Among the investigations of the pure science fellowships noted in the report may be mentioned those on techniques for ascertaining the quantitative distribution of pollution from industrial or other sources over large geographical areas, in which, for example, an hourly dust-fall sampler was developed, and the work on simpler and more reliable apparatus and techniques for measuring dust loading in stack gases. Results already obtained in a long-range investigation in the toxicological laboratory have demonstrated that the acute toxic effects of fine synthetic and natural inorganic particles may be of fundamental importance in explaining the action of fine particles on lung tissues. Zinc dust fires and zinc losses in metallizing operations were under investigation to learn why frequent fires occurred in the dust-collector system, and to see if zinc losses through the dust collector could be reduced. Preliminary studies were made in the pharmacology of eighty newly available chemicals and more advanced investigations on thirteen other compounds likely to be retailed. The plastisol shoe-pillar devised under the multiple fellowship on orthopædic appliances has relieved some two hundred cases of foot distress, an improved knee lock has been developed for an aluminium tubular brace, and the project on the traction brace has supplied a means of walking for persons with missing or dislocated hip joints.

Fundamental researches in glass science have included the design and assembly of microwave spectrographic equipment for following paramagnetic resonance absorption, the spectrophotometric study of the colour centres of irradiated natural crystalline silica samples, and the study of glass surfaces. Under the multiple fellowship on the properties of synthetic rubber, increased attention has been given to molecular size, chain stiffness and the extent to which the long-chain molecules may deviate from linearity because of branching. A semi-quantitative method has been developed for estimating the degree of branching in diene polymers, and research on the dynamic and flow properties of concentrated solutions of polymers has resulted in a theory of flow of visco-elastic materials which accounts for non-Newtonian viscosity, dynamic behaviour and the 'normal stress' or Weissenberg effect. The fellowship on artists' materials has succeeded in isolating factors involved in the ageing of spirit varnishes and in developing materials superior in each respect. Under the multiple fellowship on computor components two novel devices for storing binary information were developed and tested, and the non-linear voltage-current characteristics of semi-conducting materials were further applied in constructing complete logical switching circuits.

Researches under the applied science fellowships included the development of an improved synthetic lubricant for horological instruments; the improvement of selenium power rectifiers; the development of improved methods for testing the effect of weathering on glazes and coating materials for bricks and tiles, and of a more satisfactory method for determining the refractoriness of materials used in industrial furnaces; and studies of the dynamic properties of glass at temperatures in the transformation region, which point to the possibility of manufacturing glass with a permanently oriented structure. The ceramic chemicals fellowship has concentrated its effort on simplifying enamel formulations so as to determine more precisely the effects of varying amounts of single components and of combinations of two or more components. Under the abrasive grinding wheel programme, investigation of factors which influence residual stresses in ground surfaces of tool steel has been extended to a study of the effect of grinding severity on residual stresses in ball-bearing steel. Another fellowship is exploring the chemical behaviour of silicon carbide with the view of finding new uses for this compound; the chemical storage fellowship has investigated widely the storage of aminoethyl alcohol, lard, tallow, raw sewage sludge, calcium carbonate and acetylene, and much work was done on the cause of cracking in making welded joints and on the properties of the metal in welded joints. Further progress is reported in the development of the icosasphere, a new type of spherical tank, and research continued on components for supersonic wind tunnels, as well as on the 'Stypol' resins, a series of liquid thermosetting materials devised by the Robertson multiple fellowship on protected metals. Research was started on the chemistry of the nickel sulphides, and the multiple fellowship on coal-waste control has recommended methods of constructing refuse piles that assure a desired degree of resistance to spontaneous, incidental or deliberate ignition and has studied in the field a number of methods of extinguishing refuse fires.

The multiple fellowship on acid recovery has extended its scope to include the investigation of other wastes from the manufacture of steel, besides spent pickle liquor, and a survey of literature on the toxicity to aquatic and animal life of substances in streams and on tastes and odours has induced an investigation to determine whether a balance between phenol-consuming and phenol-producing organisms can result in a phenol equilibrium concentration. The chemical potentialities of pyridine were being studied, as well as the development of methods for the treatment and disposal of industrial wastes, the utilization of the ethylbenzene in aromatic petroleum-naphtha fractions for the manufacture of styrene, and the suitability of plastic pipe in a low-pressure distribution system for natural gas. A study of the kinetics of the oxidation of lubricating oil has been leading to new concepts of the function of additive materials in the process, and work on hydrocarbon synthesis over catalysts of the iron group was being completed. Much effort was being given to the development of analytical techniques for detecting and determining the sulphur compounds of petroleum. Work continued on the composition of petroleum waxes and the relation between their composition and physical and engineering properties, and a theory has been formulated which relates the solubility of a gas in wax to the critical constants of both solvent and gas.

A chemical study of the pyrrole pigments and their relations to the chlorophylls and hæmins was resumed, while that of the chemical composition of petroleum waxes and petrolatums led to the devising of special analytical techniques for measuring the physical properties of small fractions. Further detailed research was conducted on the factors affecting absorbent efficiency in cane-sugar refinery operations, and experiments on the variation in composition of gases dissolved in purée fruit and vegetable products over prolonged storage confirmed that a fundamental reaction in discoloration is oxidation. Most of the end-products of the discoloration of fruit and vegetables are small enough to go through a dialysis membrane. Compositions containing piperonyl butoxide have now been shown to be safe and effective additions for protecting grain and other stored products from infestation by insects. Zein emulsions have been obtained which possess low viscosity at high solid content and yield films comparable in clarity, gloss and resistance to water to coatings obtainable from alcoholic solutions. Investigations of industrial fabrics have centred on the improvement of dimensional stability and resistance to heat, water and chemicals, and those on alkyd resins indicate the value of 1 : 3-dimethyl-2-hexenolide as component. Work on the utilization of non-ionic surface-active agents has progressed, and much was done on test methods for evaluating soil conditioners and on the utilization of vinyl resins and silicones.

ROTHAMSTED EXPERIMENTAL STATION

REPORT FOR 1953

IN the annual report for 1953 of the Rothamsted Experimental Station*, it is apparent to the most casual reader that the research staff of the Station have been by no means idle during the year covered by the report. The rapid expansion in the scope of Rothamsted's activities since the Second World War—there are at present approximately three hundred and seventy people actively engaged in research and administration—has necessitated an active building programme, and several new buildings are being provided to meet the more pressing needs for accommodation.

In the Chemistry Department the assessment by laboratory and field tests of the agricultural value of water-insoluble phosphates is receiving attention in view of the attempts made by manufacturers to economize in the use of sulphuric acid for phosphatic fertilizer production. In general, the outstanding merits of water-soluble phosphates on most classes of land have again been evident, particularly when used as a starter dose placed close to the seed; but on some soils and with certain crops, various forms of insoluble phosphates have yielded results comparable to superphosphate. On all classes of soil, with potatoes and swedes, dicalcic phosphate in finely divided form gave results only slightly inferior to superphosphate; silicophosphate gave good results with potatoes on very acid soils, but was markedly less effective on moderately acid and neutral soils. On the other hand, 'Gafsa' phosphate was ineffective for potatoes on even very acid soils. All three forms gave good results with swedes. Experiments with nitro-phosphates indicate that the phosphate in these compounds has a value akin to that in high-soluble basic slags.

Work on fertilizer placement with potatoes indicates that with moderate dressings better results follow when the fertilizers are placed than when broadcast; the reverse is the case when heavy dressings are applied. With horticultural crops—lettuce, cabbage, beetroot, broad beans and runner beans—better results are obtained by placement of fertilizer.

In the Physics Department, work on the crumb structure of soils continues, and a technique for measuring the resistance of crumbs to dispersion developed. Using this technique on grass and lucerne plots sited on a field that had been under arable cultivation for many years, it has been established that two to four years under grass has materially improved the cohesion of the surface crumbs. By using a deep-rooted crop to dry out the subsoil during the summer, the permeability of heavy clay soils during the winter months may be improved, a point of practical importance to those concerned with drainage of heavy clay soils.

A simple method for measuring the deficit of divalent ions in soils flooded by sea water has been devised and will be used for estimating the dressings of gypsum needed on such land to prevent breakdown of crumb structure during the next few years.

The production of antibiotics in the soil by certain Actinomycetes and their influence on combating root-infecting fungi is being studied by the Soil Microbiology Department. Such antibiotics tend to be adsorbed and rendered inactive by certain soil constituents, particularly the clay fraction, and attempts are being made to ascertain which Actinomycete antibiotics are least affected in this way and to measure their activity in various types of soil. Pot experiments have definitely confirmed that root rot by *Helminthosporum sativum* is significantly reduced by some of the Actinomycete strains.

---

* Report of the Rothamsted Experimental Station for 1953. Pp. 228. (Harpenden: Rothamsted Experimental Station, 1954.) 7s. 6d.

The work on the nodule organisms of legumes has reached an interesting stage. The number of nodules developing on the root is apparently determined more by the susceptibility of the root to infection than by the population of the nodule bacteria surrounding it, and in the case of clover it has been shown that hereditary factors influence the time at which the nodules first appear, the number of nodules produced and their effectiveness in fixing nitrogen.

In the Botany Department it has been established that some of the ill effects of excess of manganese, vanadium and molybdenum may be prevented by increasing the supply of iron, and farmers troubled with wild oat infestation will learn with interest that the sowing of winter corn instead of spring corn will result in lessened germination, and production, of new seeds by this plant pest.

Heat therapy as an aid in the control of plant viruses has received the attention of the Plant Pathology Department, with variable results. It would appear that viruses of spherical shape are inactivated by heat treatment but not rod-shaped viruses. Much information on other aspects of virus infection is contained in the report.

The study of enzyme action is the main concern of the Biochemistry Department. Special attention is being paid to ribonuclease in view of the fact that every plant virus hitherto obtained in a pure state has proved to be a ribonucleoprotein. Oxidative enzymes are also being studied, since plant hormones and growth regulators are subject to enzymatic oxidation, and such enzymes by their effect on the concentration of these substances may play a part in the regulation of plant growth. The enzymic breakdown of cellulose and chitin is also receiving attention.

Eelworms, which are becoming an increasing menace to cereal and potato growers, are being intensively studied by the Nematology Department. In attempts to combat this pest, endeavours have been made to discover resistant crop varieties and suitable crop rotations for infected land. One spring and two or three winter oat varieties appear to be resistant to stem eelworm attack, but no commercial variety of potato resistant to potato tuber eelworm was discovered. Attempts are being made to obtain resistant varieties by crossing commercial strains with *Solanum indigenum*, which is resistant to eelworm attack. Work is also in progress on root diffusates which stimulate the hatching of eelworm cysts, and on the control of eelworm by the application of chemicals to infested soils.

In the Entomology Department the work on insect migration, on the influence of weather on insect populations, on gall midges of economic importance and on aphid problems has continued. Three points of interest may be singled out: lepidopterous larvæ apparently develop and grow more rapidly when crowded together than when solitary; aphids do not normally reproduce unless they have previously made a flight, however brief; and wheat bulb flies have been successfully bred under laboratory conditions.

The Bee Department's report contains much of importance to apiarists. The fumes produced by adding small quantities of ammonium nitrate to burning smoker fuel provide a simple anæsthetic for use when transferring bee colonies from one site to another a short distance away, since on recovery the bees lose their tendency to drift back to the original site. The known ability of worker bees to cluster together when dispersed in an area in total darkness is associated with their search for warmth and food, and, if a queen is present, for 'queen substance'. Queen honey bees secrete on all parts of their bodies this 'queen substance' which is eagerly sought for by the worker bees, and is considered to be most important in the maintenance of colony cohesion. A temporary shortage of supply of this substance or a breakdown in its distribution leads to toleration by the workers of eggs and larvæ in the queen cup cells and a consequent tendency to swarm. The report contains suggested rules, based on this work, to be followed when introducing to colonies mated queens of any age or strain.

The Insecticides and Fungicides Department has continued its work on particle size and toxicity of suspensions of contact insecticides, and on insect esterases and their inhibition by organo-phosphorus compounds. The work on the relationship between the insecticidal activity and the chemical constitution of pyrethrin-like compounds has now reached an important stage. By means of displacement chromatography four known active constituents have been separated from each other and from some inactive constituents of pyrethrum extract, and their relative toxicities compared. The report also contains much useful information on bio-assay techniques, toxicity-persistence of insecticidal deposits, the mechanism of the selection of strains of insects resistant to insecticides, and, in the field, on the control of *Aphis fabæ* on field beans, control of the vectors of potato virus and control of wireworms.

CITY MUSEUM, BRISTOL

REPORT FOR 1953

THE two well-produced and excellently illustrated booklets*—the annual report of the City Museum, Bristol, for 1953 and the new handbook to Stratford Mill in Blaise Castle House Folk Park—bear unmistakable testimony to that invaluable tripartite combination, an appreciative committee, an understanding and far-seeing director and a loyal and enthusiastic staff.

The inside of the cover of the Museum report details activities and offerings of specimens, collections and services of which Bristol can justly be proud, and the report shows the gratifying and growing response received. The main duty of the Museum is rightly taken to be the portraying of local history and local natural history, and the commendable progress made is recorded in the succeeding departmental reports. Rearrangement of the collections is being made to bring the exhibition series into accord with both modern scholarship and contemporary museum display methods. The new gallery of geology has been opened, and the famous series of Lias and Inferior Oolite ammonites in the Tutcher Collection classified and labelled. Popular study of botany has been encouraged by the wild plant table throughout three of the seasons, while even winter had its offering of displays of twigs. British birds and their nests have been prepared for exhibition, while for students accessions include skins of mammals and birds from the region and the Marle collection of shells, many from the district.

* City Museum, Bristol. Report of the Committee for the Year ended 31 December, 1953. Pp. 16+2 plates.
Stratford Mill in Blaise Castle House Folk Park. Pp. 8+2 plates. 6d. (Bristol: City Museum, 1954).

The work of the department of archæology ranges from salving small Romano-British relics to erecting "an unclimbable fence" around the Roman villa at Kings Weston, and one wonders if there is any connexion between this and the reference to the unruly behaviour of certain young visitors on Sunday afternoons—a time-honoured complaint that belies "The better the day, the better . . .". Bristol played its part during the year by organizing an administration course for students for the Museums Association diploma, and in its turn sending members of its own staff to technical courses elsewhere. Twenty major temporary exhibitions were staged in the Museum, 3,420 cases of specimens were circulated to schools, etc., and 8,118 children attended for lessons—an entirely creditable performance.

The little handbook to Stratford Mill, costing sixpence, gives on art paper some five pages of text on the history and mechanism of corn-mills in general, and this one in particular, together with a photograph of the mill on its new site and an attractive drawing of its working parts. May we have others on the thatched dairy and the gypsy caravan ?

BLUE HILL OBSERVATORY OF HARVARD UNIVERSITY

THE report of the visiting committee to the Blue Hill Meteorological Observatory, Harvard University, Milton, Mass. (Reprint No. 7, 1953), includes the activities of the Observatory over the previous five years. During this period the facilities of the Observatory have had many users, among which may be noticed not only students working on research problems but also a number of Harvard departments, the United States Weather Bureau, the United States Air Force, the Massachusetts Institute of Technology, Clark University, Illinois State Water Survey, American Meteorological Society, Woods Hole Oceanographic Institution, Mt. Wilson Observatory, the Lowell Institute's Cooperative Broadcasting Council Station *WGBH*, and various business corporations and local towns.

The work of the Observatory staff is concerned with the following topics: evaluation of the Blue Hill and other climatic records, especially as indicators of climatic change; development of statistical aids to the forecasting of snow-storms for Greater Boston; designing and comparing station equipment and exposures; researches concerning clouds and the physics of precipitation; training of graduate students; and improvement of the library and its service. A very complete and mostly automatic record of the weather has been kept since the winter of 1884–85, when it was started by Abbott Lawrence Rotch. A record kept of the temperature in Milton by the Rev. A. Breck from 1849 has supplied further data on temperature conditions, and it appears that during the past hundred years there has been a remarkable amelioration of the climate. In recognition of the value of the Observatory's current work on climatology, the United States Weather Bureau is supplying it with standard instruments, broadcasting its monthly data and publishing its records. Under instrumentation is included an account of the work of Dr. Wallace E. Howell and Mr. John H. Conover in designing and testing new instruments for Blue Hill and other institutions. In research on clouds and precipitation, work was carried out at Blue Hill before Schaefer's experiment in November 1946 of dropping solid carbon dioxide on a cloud of supercooled droplets to make snow, and a month after this Dr. W. E. Howell successfully repeated the experiment on Mt. Washington.

Finally, mention must be made of the Observatory's Library, which is widely used by professional meteorologists all over the country, but particularly in the large group in Boston ; so great has been the demand for the Observatory's research publications that Blue Hill has always received on an exchange basis the publications of weather services, universities, research stations or institutes and individuals from all over the world.

THE COLLECTION OF DATA FROM FIRMS

THE research workers who need to collect data from firms cover a wide range of studies and use the data for many different purposes. As, nevertheless, they have many difficulties and problems in common, the Acton Society Trust held a conference on April 28 on "The Pitfalls in the Collection of Data from Firms", at which twenty-three research workers attended, drawn from universities, national research organizations, government departments, co-operative research associations and private industry. They included economists, psychologists, sociologists, statisticians and some whose particular speciality it would be hard to define.

After the formal opening of the conference by Mrs. Honor Croome, Dr. T. E. Easterfield (Department of Scientific and Industrial Research) opened the first session with a discussion of some of the main sources of error in data obtained from firms. The firm's own records may not be kept correctly, or may be kept in a form suitable for its own needs but misleading to the research worker. Information supplied in reply to questionnaires is particularly unreliable, as even the simplest question may not fit every case and may be misunderstood in many different ways.

The second morning session was opened by Mr. Stafford Beer (Samuel Fox and Co.), who spoke of the pitfalls found in data by workers doing research inside industry. Many seemingly excellent data are derived from notebooks and scraps of paper filled up by the semi-literate. Measurements may be given a misleading appearance of accuracy by being recorded to too many significant figures. Nomenclature may also be misleading, the same words being used in different senses in different places. But the worst source of error is the pure blunder : Mr. Beer himself recently reached some quite wrong conclusions by analysing a column giving furnace numbers under the impression that it gave the number of ingots in the furnace. The best way of avoiding these errors, he said, is to record the data oneself, or to control the recording. This makes it especially necessary for the research worker to have technical knowledge of the industry he is studying. Mr. Beer thought the use of automatic recording devices to be necessary if human error is to be eliminated.

In the afternoon, Mr. W. F. Luttrell (National Institute of Economic and Social Research) described his methods of collecting economic data. He said that the sending of questionnaires is useful only for collecting figures already kept in an agreed form, and even then visits to firms are often necessary. In all other cases data must be gathered personally. Mr. Luttrell starts to work in a firm by making a list of all the records which can possibly bear on the matter being investigated. Where the records do not show what is wanted, it is often possible to get it from the notebooks in which the data were first recorded; but these may have been destroyed. The notebooks are also useful for test checks—to show how the records derived from them are compiled. The cost records of firms are seldom suitable for research as they stand; it is quite common, for example, for overhead costs to be allocated in an arbitrary and distorting way, perhaps by a fixed percentage addition to labour costs. A further source of bias is the greater readiness of firms to give information about successes than about failures. The last session was opened by Mr. J. D. Handyside (National Institute of Industrial Psychology), who stressed the large amount of work involved in the various methods of avoiding errors suggested by other speakers.

The conference as a whole showed that a methodology of research on industry has grown up which cuts across the normal boundaries of a number of disciplines. It also showed that the data produced by industry to-day are not sufficiently accurate to be worthy of the elaborate methods developed by theoretical statisticians.

SIPHONOPHORA OF THE INDIAN OCEAN

STRUCTURE and taxonomy of the Coelenterata continue to interest zoologists even in this period when the concern of the majority is experimental. Since the War three major monographs have been published in Great Britain alone. The life-work of the late Cyril Crossland culminated in his report (edited by A. K. Totton) on the Madreporaria, Hydrocorallinae, Heliopora and Tubipora of the Great Barrier Reef Expedition. Following in the footsteps of Ellis, Forbes, Allman, Hincks and Browne, E. S. Russell has produced his admirable "Medusae of the British Isles". Now A. K. Totton renders no less service by the work here reviewed*.

Opportunity has been taken not only to study and report on collections made by the *Discovery II* in 1935, 1950 and 1951, but also those made by the *John Murray* and other expeditions since 1933, eight collections in all. We gain some idea of the labour involved, and so of the stimulating enthusiasm inspired initially by study of H. B. Bigelow's 'Albatros' Report on the Siphonophora. "For many years now", the author informs us, "I have been occupied with the laborious task of picking out hundreds of thousands of fragmentary specimens from plankton samples and of trying to form some idea of how many species are represented, and then attempting to apply old specific names and, where none are available, giving new ones". And again, "One may search for a very long time before being lucky enough to find a really well-preserved specimen, or a larval or other much desired stage, of some particular species. . . . There is also the inherent difficulty of dealing with fragmentary specimens. Again, many of the species occur in two phases. . . .". Meanwhile in the Discovery collections alone there are thousands of still unexamined plankton hauls.

The suspected wide distribution of Siphonophores is confirmed; no species would appear confined to the Indian Ocean or, apart from purely antarctic species, excluded from it. There is great restriction of species within the Red Sea, as there is in the Mediterranean in comparison with the Atlantic, and probably for similar reasons, namely, outflow of deep water over the sill and high minimum temperatures in deep water.

Attempts to interpret the extraordinary complexity of structure in the Siphonophores, on the success of which must depend final conclusions about classification, raise what are among the most perplexing, if not *the* most perplexing, problems in zoology. The fantastic development of polymorphism probably involves, apart from precocious budding, both neoteny and early manifestation in ontogeny of structures or individuals which appeared late in phylogeny. Totton pays tribute to the morphological acumen of Garstang, who made fundamental contributions by revealing that the 'medusome' theory of Haeckel is untenable and that the pelagic habit of the Siphonophores probably represents prolongation of an actinula-like larval phase.

Unfortunately Garstang failed to realize the extent of the dissimilarity between the Chondrophora (= Disconanthae) comprising *Velella*, *Porpita* and *Porpema* and the Siphonophora (= Siphonanthae). As Totton clearly shows, these represent distinct orders, not suborders. The former are really floating Tubulariid hydroid-phases of inconspicuous Codonid medusae. The ancestral Siphonophora, on the other hand, had probably a larval polypoid stage and an adult medusoid stage, both, in various structural manifestations, eventually making simultaneous appearance in the same colony.

This is a beautifully produced report, admirably illustrated by text-figures and plates, a credit alike to author and to publisher.

THE CYTOCHROME *b* COMPONENT OF CHLOROPLASTS

By DR. ROBERT HILL, F.R.S.

Department of Biochemistry and the Molteno Institute, University of Cambridge

DAVENPORT[1] isolated etiolated chloroplasts from barley seedlings grown in the dark and observed in them the spectrum of cytochrome *f*. As the chloroplasts in this case are developed to a size and number approaching those in the normal green leaf, this appeared to establish beyond doubt that the cytochrome *f* isolated from green leaves was not an artefact but was a characteristic component of the green cell. The chloroplasts of the etiolated barley leaves were found to contain also a cytochrome *b* component[1,2] present in amount definitely larger than that of cytochrome *f*. The *b* component, which here will be designated b_6, was autoxidizable in the chloroplast suspensions and did not combine with carbon monoxide. It was not found possible to remove it from the solid material in an unmodified form. It was easily modified by treatment with various organic solvents and then reacted with carbon monoxide. The position of the sharply defined α-band was visually estimated as 563 mμ, and after modification either by reagents or by heating to 70° the α-band became broader and less sharp. It has been found that by treating chloroplasts from normal green leaves with acetone and suspending the chlorophyll-free residue in buffer at *p*H 7, on reduction with sodium dithionite ($Na_2S_2O_4$), the α-band corresponding with that of the b_6 component present is similar to that observed in the etiolated barley chloroplasts. An apparently identical b_6 component was found to be present, together with cytochrome *f*, in *Chlorella*[3]. If the treatment of the chloroplast material with acetone is carried out rapidly in the cold, the α-band of b_6 is sharp and carbon monoxide produces only a slight weakening effect on the absorption spectrum, showing that only a portion of the hæm reacts. Thus it was concluded that the rapid removal of the chlorophyll with acetone only modifies a small amount of the b_6 component. In contrast to this, treatment of the Keilin–Hartree preparation of the cytochrome system with acetone at once destroyed the component *b* and allowed the resulting denatured hæm protein compound to combine with carbon monoxide. This made it probable that the b_6 component observed in the chloroplast differs from *b* in the normal cytochrome system. Experiments on the oxidation-reduction behaviour of cytochrome b_6, when in equilibrium with the ferri–ferro–oxalate system, $E_0'h$ = zero[4], now confirm that it is different from the *b* component of the normal cytochrome system.

Preparations of the chloroplasts from etiolated barley were made according to Davenport. They were suspended in 0·5 *M* potassium oxalate and *M*/15 phosphate buffer at *p*H 7. Ferric iron was added to give a concentration of *M*/1,000, and part of the mixture was examined spectroscopically in a vacuum tube in absence of air. The mixture was then titrated *in vacuo* with a solution of ferrous sulphate (*M*/2). As soon as a minute amount of ferrous iron was added, there appeared to be almost complete reduction of cytochrome *f*; but no reduction of cytochrome b_6 was observed. No reduction of b_6 could be detected until the logarithm of the ratio ferrous/ferric iron was equal to 0·16. The titration was continued and the amounts of b_6 reduced estimated by visual comparison with another portion of the chloroplast preparation reduced with sodium dithionite. The practicable limit was reached when the logarithm of the ratio of the ferrous to the ferric iron was equal to 1·1, and at this point the cytochrome b_6 was about half reduced. In making these observations time was allowed for equilibrium to be approached, and the system was shown to be reversible with respect to the ferri–ferro–oxalate system. The result is shown in Fig. 1, where the

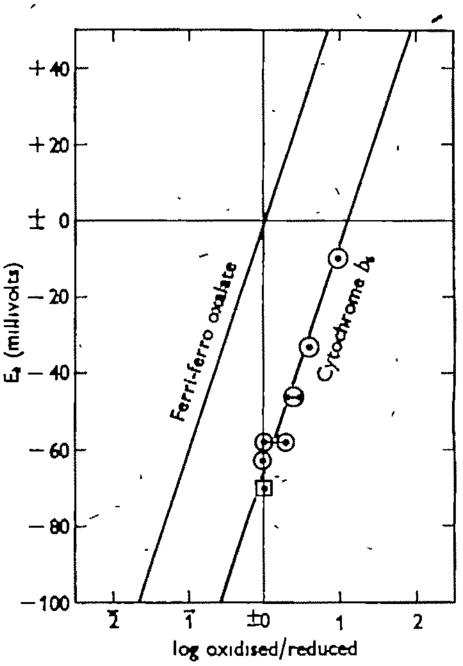

Fig. 1. Oxidation-reduction equilibrium of cytochrome b_6 with the iron oxalate system at *p*H 7 and 20°
⊙, Barley; ⊡, cabbage

logarithms of the ratios of oxidized and reduced cytochrome b_6 are made equal in potential to the corresponding values derived from the logarithms of the ratios ferric/ferrous iron in equilibrium. The results indicate that the $E_0'h$ of cytochrome b_6 at *p*H 7 is of the order of −0·06 V., and definitely more negative than the ferri–ferro–oxalate system. The characteristic potential of component *b* of cytochrome in a Keilin–Hartree muscle preparation was estimated to be nearly equal to that of the iron oxalate system.

It was found that preparations of chloroplasts made from the pale yellow mesophyll tissue of cabbage hearts contained appreciable amounts of both cytochrome *c* and *a* in addition to the components *f* and b_6; thus considerable contamination with other cytoplasmic particles was probable. Such a preparation, when examined in the presence of the iron oxalate system, showed a definite amount of a reduced *b* component when the oxidation-reduction potential was estimated as zero. If it was assumed that this corresponded to half-reduced cytochrome *b* of the normal cytochrome system present together with oxidized b_6, the potential corresponding to half-reduced b_6 after further addition of ferrous iron was estimated to be −0·07 V.

The chloroplasts thus contain a characteristic cytochrome component which is autoxidizable and which has, in the barley chloroplast preparation, an oxidation-reduction potential of about −0·06 V. The presence of cytochrome b_6 could account for the experimentally observed reducing properties of chloroplast preparations when illuminated in the presence of certain hydrogen acceptors. As this cytochrome component can be readily reoxidized by molecular oxygen, it could limit the range of possible 'chloroplast reagents' to those with characteristic oxidation-reduction potentials more positive, at neutral *p*H, than about zero volt (*r*H 14). The difference between the characteristic oxidation-reduction potentials of cytochrome *f* and b_6 is

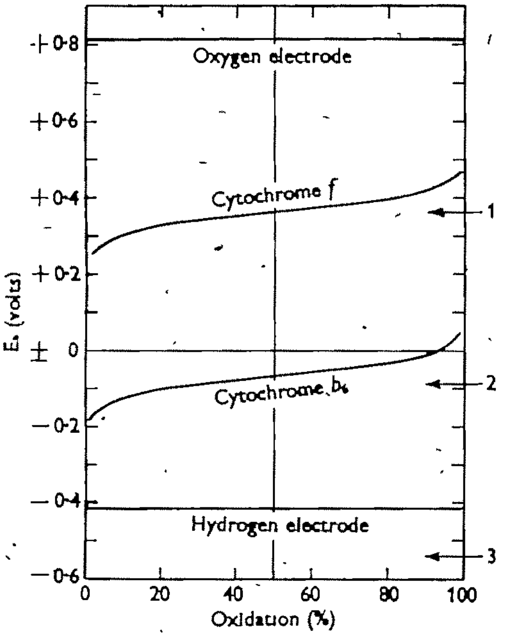

Fig. 2. Oxidation-reduction potentials of cytochromes *f* and b_6 in relation to the hydrogen electrode at *p*H 7. The arrows represent three hypothetical oxidation-reduction steps referred to in the text

approximately equal to the difference between the potential of cytochrome *f* and the oxygen electrode. Davenport and Hill[5] pointed out that the free energy of the reaction at *p*H 7:

$$4f\,(\mathrm{Fe}^{2+}) + \mathrm{O}_2 + 4\mathrm{H}^+ = 4f\,(\mathrm{Fe}^{3+}) + 2\mathrm{H}_2\mathrm{O}$$

(representing the oxidation of four equivalents of cytochrome *f* by one molecular equivalent of oxygen) was equal to the energy of one mol.-quantum of light corresponding to the maximum of the fluorescence spectrum of chlorophyll *a* in the plant. This is shown in the diagram, Fig. 2, where also the potential of b_6 is shown in relation to a second hypothetical oxidation-reduction step. If a third step is postulated, this would correspond to a system the characteristic potential of which, at *p*H 7, would be slightly less than that of the hydrogen electrode. These three steps are sufficient to cover (in theory) the whole range of hydrogen transport required for photosynthesis. The chloroplast reactions *in vitro* observed up to the present time appear to cover the first and second steps only, and this limitation may be due to the ready oxidation of cytochrome b_6 by the oxygen liberated during the photochemical reduction of the hydrogen-accepting reagent.

In the living cell, it seems possible that the cytochrome b_6 may be in a nearly completely reduced state even though oxygen is being produced. With the leaves of the 'golden varieties' of certain plants, a sharply defined absorption band can be observed visually with the microspectroscope at 563 mμ. When chloroplast preparations from the plants are examined, no absorption band can be observed in this position until the preparation is reduced with sodium dithionite; in this condition, however, the absorption band is broadened towards the region of shorter wave-lengths. The absorption might then be due to the mixture of reduced cytochrome *f* and b_6; if this is so, it would mean that in an illuminated leaf (of a golden variety) cytochrome b_6 is reduced while cytochrome *f* is oxidized. This represents obviously a definite amount of available chemical energy, as may be seen from Fig. 2. It should not be assumed at this stage, however, that cytochrome *f* and b_6 alone determine the course of the hydrogen transport. The fact that the absorption spectrum of the chlorophyll in a leaf shows a relative minimum in the region of the α-bands belonging to cytochromes of groups *b* and *c* makes the two particular cytochrome components (b_6 and *f*), in a few cases, accessible to direct observation in living cells.

This work is part of a research programme supported by the Agricultural Research Council.

EFFECT OF PITUITARY STALK SECTION ON LIGHT-INDUCED ŒSTRUS IN THE FERRET

By B. T. DONOVAN and
PROF. G. W. HARRIS, F.R.S.

Department of Neuroendocrinology, Institute of Psychiatry,
Maudsley Hospital, London, S.E.5

It is well known that œstrus may be induced in the sexually quiescent ferret by artificially increasing the length of day during the winter months[1]. This response is dependent on increased anterior pituitary secretion of gonadotrophic hormone, since it is abolished by hypophysectomy[2]. The sensory receptors for the light stimulus appear to be the eyes, since animals with the optic nerves cut fail to respond to extra illumination[3].

Recent reports from the Department of Anatomy, University of Birmingham, have dealt with the anatomical pathways underlying the light-induced œstrous response. Thomson[4] has investigated the optic structures involved. His conclusion that the optic nerve fibres are essential for the response is in agreement with previous workers; but his experimental data are unsatisfactory owing to the techniques employed to blind the animals. The three methods used were: (i) section of the optic nerve fibres inside the sheath of the optic nerve; (ii) midline sagittal section through the optic chiasma; and (iii) incision between the posterior margin of the optic chiasma and the anterior limit of the hypothalamus. From the neuroanatomy of the visual pathway there is no reason for believing that the animals subjected to the latter two procedures, at least, would be blind, and since the post-mortem examination of the brains of these animals has not been made (Thomson, personal communication), this work is unconvincing.

The pathway traversed by the light stimulus between the optic nerves and anterior pituitary gland is unknown. It is possible that the structures involved are nerve fibres passing from the optic tract into the hypothalamus, and the hypophysial portal vessels of the pituitary stalk. There is no good evidence of a direct secreto-motor nerve supply to the adenohypophysis[5].

Thomson and Zuckerman[6] have reported the results of experiments in which the light-induced response of ferrets was studied after section of the pituitary stalk. The pituitary stalk was cut by a buccal approach, and out of twenty-three animals so operated the stalk was found to be completely severed in seventeen. Two ferrets that reacted to the light stimulus by becoming œstrous were found to lack any vascular connexions between the median eminence and the adenohypophysis. On the basis of these two animals, the conclusion was drawn[6,7] that the hypophysial portal vessels do not form part of the pathway by which the stimulus reaches the anterior pituitary gland.

In the present study, a temporal approach to the hypothalamus and pituitary has been used. This operative exposure has several advantages, for the present purpose, over the parapharyngeal or buccal route: (i) it permits an excellent view of the whole pituitary region, (ii) it allows the insertion of a large waxed paper plate (5 mm. × 3 mm.) between the cut ends of the pituitary stalk, and (iii) it leaves a clean field in the pituitary region (intact skull base and dura mater), so that the microanatomy of the stalk area can be more easily studied at a later date.

The pituitary stalk of twenty-four ferrets has been exposed by this method. In four animals the stalk was left intact, in six simple stalk section was performed, and in fourteen the stalk was cut and a paper plate inserted between the hypothalamus and pituitary gland. Twelve of these twenty-four ferrets became œstrous during the winter of 1953–54 when exposed to prolonged illumination. These included the four blank-operated control animals, five of the six subjected to simple stalk section and three in which a paper plate had been inserted. After killing, the vascular system was perfused through the aorta with 200 ml. diluted mandarin black indian ink (1 part ink : 3 parts distilled water), the head fixed in formalin, decalcified and a block of tissue containing the hypothalamus, pituitary gland and base of the skull embedded in low viscosity nitro-cellulose. Serial sections were cut at a thickness of 130–200 μ (usually 160 μ). In two cases the pituitary region of anœstrous ferrets with plates was dissected, without indian ink perfusion, and the gland placed in Susa's fixative for more detailed cytological study.

Histological examination of the pituitary region gave the following results:

(a) The pituitary stalk had been successfully sectioned in all but the blank-operated animals.

(b) The appearance of œstrus could be correlated with the presence of vascular connexions between the median eminence of the tuber cinereum and the anterior pituitary gland. These connexions were clearly visible in all eight stalk-sectioned ferrets that became œstrous. Study of the three animals in this group, in which plates had been inserted, showed that the plates had been misplaced (two were situated too anteriorly and one obliquely) and that vascular connexions had been re-established around the borders of the plates. No case of œstrus was observed in the absence of vascular connexions.

(c) The anœstrous animals had few, if any, vascular connexions between the median eminence and anterior pituitary gland. The animals in this group (one simple section, and nine with plates) showed a well-marked primary plexus and a well-vascularized adenohypophysis.

(d) Some atrophy of the pituitary gland occurred in all animals in which the stalk was sectioned. It may be seen from Table 1 that the posterior lobe of the stack-sectioned ferrets is less than 50 per cent the volume of the posterior lobes of the blank-operated animals, whereas the anterior lobe (pars distalis) has a volume of more than 75 per cent that of the controls. There was no correlation between the development of œstrus in the stalk-sectioned animals and the extent of anterior lobe atrophy.

Table 1. COMPARISON OF THE VOLUMES OF THE PITUITARY GLANDS AND OF THE ANTERIOR AND POSTERIOR LOBES IN THE BLANK-OPERATED, ANŒSTROUS AND ŒSTROUS FERRETS

These figures were obtained by the 'paper weight' method, and are the averages for the animals in each group

	No. in group	Total volume	Anterior lobe	Posterior lobe
Blank-operated (œstrus)	4	100	100	100
Stalk-cut (anœstrus)	10	73	95	45
Stalk-cut (œstrus)	8	61	80	39

From these results it is concluded that the hypophysial portal vessels form a necessary part of the pathway of the light-induced œstrous response in the ferret. This conclusion is in keeping with much previous work[8]. The suggestion of Greep and Barrnett[9] that the disturbance of reproductive activity following section of the pituitary stalk is due to ischæmic atrophy of the pars distalis is unlikely to be true for the rat, and can be eliminated as a possible explanation of the present results on the ferret.

The conclusion of Thomson and Zuckerman[6] that light-induced œstrus occurs in the absence of nervous or vascular connexions between the tuber cinereum and adenohypophysis may best be explained on the following grounds:

(i) Their conclusion was based on the results obtained in only two animals.

(ii) The surgical approach used by these workers (buccal route)[10] gives poor facility for placing plates between the cut ends of the stalk, and the plates are "with a few exceptions . . . eliminated from the wound"[6]. Further, this operation often results in anatomical disorganization of the pituitary stalk region, which complicates the final histological study.

(iii) The microscopic study of serial sections through the pituitary–hypothalamic region was made after imbedding the specimens in wax and sectioning at 10 μ (Zuckerman, personal communication). In our experience, it is necessary to imbed in 'Celloidin' and cut thick sections at 100–200 μ in order to obtain a clear picture of the vascular anatomy.

(iv) Through the kindness of Dr. Thomson and Prof. Zuckerman, we have had the opportunity of examining sections through the pituitary region of one of their critical ferrets. Inspection revealed that a significant proportion of the visible blood vessels did not contain indian ink. Conclusions drawn from incompletely injected specimens must be regarded as unreliable. Composition of the Earth's Outer Core

ATTENTION has lately been given to the following set of four postulates: (*a*) the Earth, Mars and Venus have a common primitive composition; (*b*) compressibility is essentially a smoothly varying function of pressure at pressures beyond $0 \cdot 4 \times 10^6$ million atmospheres in all three planets; (*c*) the outer core of the Earth is a high-pressure modification of ultrabasic rock; (*d*) each planet has an inner core chemically distinct from the matter in the outer core.

With the use of an Earth model referred to as Model B[1], I showed[2,3] that this set of postulates yielded values of the mean densities of Mars and Venus and of the ellipticity of figure of Mars that were within the standard errors of the observational data available to me at the time. The purpose of the present communication is to direct attention to implications of revisions of the data in question, and to bring up to date a statement in my recently published book[4].

I am indebted to Dr. G. P. Kuiper for kindly supplying me with the latest information on revisions of the astronomical data. He informs me that the most probable diameter of the solid surface of Mars is now about 3,330 km., as against 3,389 km. computed using postulates (*a*)–(*d*); also that estimates of the diameter of Venus are being reduced. In addition, Dr. Kuiper has informed me that it is innate in Woolard's work[5] that, while the observed ellipticity of Mars is not sensibly changed from Struve's value which had been used by me in my previous calculations, the standard error of the determination has been reduced by roughly two-thirds. This has the effect of making the ellipticity calculated on the basis of (*a*)–(*d*) different from the observed value by about three times the standard error of the latter.

The effect of these revisions is to demand some reconsideration of postulates (*a*)–(*d*), especially (*c*). A significant feature of the revisions is that they all point the same way. Examination of a diagram of Bullen and Low[6] shows that the influence of postulate (*d*) is to increase the computed mean diameters of both Venus and Mars above the values which would be yielded if the inner core were composed of iron silicate rather than of purely uncombined iron. The effect of this is to show that, given the masses of Mars and Venus and assuming the postulate (*a*), then increasing the assumed amount of uncombined iron in their cores diminishes the calculated diameters. Further, with the use of postulates (*a*)–(*c*), it had been found[3] that the assumption of (*d*) led to an estimated ellipticity of Mars of 1/188, as against 1/181 if the inner core contained no uncombined iron. Thus increasing further the assumed quantity of uncombined iron in the core has the effect of bringing the estimated ellipticity of Mars closer to Woolard's value of $1/191 \cdot 8$ ($\pm \frac{1}{2}$ per cent).

On the assumption that the terrestrial planets have a common primitive composition, all three of the astronomical revisions indicate that the Earth's outer core is composed of a mixture of uncombined iron and of material the representative atomic number of which is smaller than that of iron. It is interesting that this conclusion finds support in two other independent investigations. In 1952, Birch[7] concluded that the density in the outer core "is perhaps 10–20 per cent lower than the density of iron or nickel-iron under the same conditions"; Birch suggested alloying with other materials as a possible explanation of the discrepancy. Again, recent work of Knopoff and Uffen, kindly communicated to me in advance of publication, indicates a mean atomic number of 22 for the region *E*, a value four units less than that for iron, six units less than that for nickel.

The lighter material which seems to be present in the outer core may consist of material such as the rock fayalite. The latter may be in the form of a high-pressure modification as assumed in postulate (*c*), although Dr. W. M. Elsasser informs me (in a personal communication) that there are serious theoretical difficulties in assuming an accompanying density increase in a ratio as high as $1 \cdot 6$, which is the ratio of the densities on the two sides of the boundary between the core and mantle of the Earth. It is possible that a more detailed calculation which I hope to carry out will throw some light on this question.

An incidental point, of some cosmological importance, is that it still appears possible, by a suitable modification of postulate (*c*), to reconcile seismic and astronomical data with the hypothesis of a common primitive composition for the Earth, Mars and Venus, although further calculation is needed to confirm this. Such a result is important in that earlier work[8] appeared to have excluded this hypothesis. Moreover, there is little difficulty in adapting any model to bring the Moon into the same picture. Mercury remains an apparent exception; but I have earlier suggested[9] that observations of the present-day Mercury may be inapplicable to the primitive Mercury.

Proposal for a New Æther Drift Experiment

IT is interesting to learn from L. Essen's communication[1] that the accuracy of measurement of frequencies in the 9,000 Mc./s. region attained at the National Physical Laboratory with existing equipment is high enough for the new æther drift experiment to be carried out. I understand that preparations have been made for the same purpose at the Zeeman Laboratory of the University of Amsterdam by F. Bruin, to whom I suggested the experiment last summer.

May I point out that the experiment proposed by me[2] is not a repetition of the Michelson–Morley experiment, in which interference between *progressive* waves is observed. It is an experiment with *standing* waves, and resonance frequencies are measured for different orientations of the axis of the resonator.

A fixed distance ('axis') between two parallel mirrors, moving with uniform velocity through the æther of classical physics, represents a variable 'effective optical length' for standing waves, depending on the angle between that velocity and the axis. Therefore, according to classical optics it ought to be impossible to keep the resonant frequency of a cavity resonator constant for any length of time if the resonator is fixed in a certain position in the laboratory; for the orientation of its axis relative to the earth's velocity with respect to the æther changes in the course of the day and the year. The resonant frequency would in general change periodically between two limits during one stellar day, and the frequency-range would periodically expand and contract annually, reaching its greatest width when the directions of the earth's orbital movement and of the movement of the solar system coincide.

Analysis of records of frequency fluctuations of a stationary cavity resonator could in principle give information on whether an æther drift exists; but it is most probably not possible to keep the system free from external disturbances for a sufficient length of time.

Transformation in a Titanium - Chromium Alloy

IN metallic systems which may undergo a diffusionless (or martensitic) transformation on cooling, it has been found that transformation may also be induced above M_s by plastic deformation under favourable conditions[1]. The phenomenon has been investigated exhaustively in steels and in one or two non-ferrous systems; but its study in titanium alloys has received little attention up to now. Many titanium systems show a very interesting phenomenon in that a rather abrupt drop in M_s occurs when the alloy content is increased above a certain critical value[2]. Such an effect is not to be expected from general thermodynamic considerations of the constitution diagrams and has been attributed to the occurrence of some form of stabilization[3]. To examine this in greater detail, an investigation was made of the effect of deformation on a titanium – 10 per cent chromium alloy, for which, according to extrapolation of known data, M_s should be about 200° C.[3], although the alloy can be cooled down to – 196° C. without transformation occurring.

The alloy used was arc-melted in an inert gas (argon) atmosphere and received in the fully β-condition, as metallographical and X-ray examination confirmed. Specimens about $\frac{1}{16}$ in. × $\frac{1}{4}$ in. × $\frac{1}{4}$ in. were cut off under water and deformed by compression between two steel blocks; low-temperature deformation was carried out by surrounding the specimen and blocks with liquid nitrogen. X-ray examinations were made at room temperature using filtered copper $K\alpha$ radiation and an aluminium foil 0·002 in. thick placed over the photographic film to absorb the secondary radiation. The surface of the specimens were electrolytically polished and set at an angle of 20° to the incident beam, with an oscillation to 25°, in a cylindrical camera of 10 cm. diameter.

Room temperature deformation (expressed in terms of true stress and strain) up to 20 per cent (corresponding to a stress of about 150 kgm./mm.^{2}, 210,000 psi) produced no transformation of the body-centred cubic structure. The diffraction pattern obtained from the electropolished surface of the specimen parallel to the compression axis showed only spotty body-centred cubic lines due to coarse grain size. The same result was obtained after a heat treatment of 42 hr. at 1,100° C. (to eliminate any inhomogeneity that might have existed in the alloy as received) followed by quenching in 20 per cent sodium hydroxide solution at 10° C., and then deforming at room temperature.

Similarly, deforming at – 196° C. until fracture occurred (at about 17 per cent strain and 175 kgm./mm.^{2}, 250,000 psi) gave no definite evidence of transformation either, judging by the X-ray pattern from the fractured surface. By pre-straining (in compression), however, approximately 2 per cent at room temperature prior to the sub-zero deformation quite definite diffraction lines of the hexagonal close-packed structure were discovered in addition to those of the body-centred cubic structure; the sub-zero deformation was produced at – 196° C. by a stress not much above 200 kgm./mm.^{2} (300,000 psi), at which the specimen fractured (the amount of deformation could not be measured as the specimen fell apart on removing it from between the deformation blocks).

These observations confirm that the β-phase is very stable thermodynamically, and in addition indicate that it has also considerable mechanical stability, which, however, may be influenced under certain conditions.

This work was done at the Case Institute of Technology, and Prof. A. R. Troiano's interest is gratefully acknowledged.

A Light Source for Köhler Illumination

THE advantages of Köhler illumination have recently been discussed by Barer and Weinstein[1], and also the difficulties involved when a single auxiliary lens is used. They describe a new microscope lamp with a variable auxiliary lens-system which overcomes these difficulties. For most purposes, however, a single auxiliary lens can be used if a sufficiently large and reasonably uniform light source is available. This can usually be obtained without serious loss of light if a piece of ground glass can be placed very close to the filament of a suitable car headlamp bulb or projector bulb; but unfortunately, in most lamps, whether commercially available or home constructed, it is difficult to arrange this. A satisfactory method is to grind lightly a circular patch on the end of the bulb, using a mixture of fine well-worn 'Carborundum' powder and water on a glass plate. It is not suggested that this provides so versatile an illuminant as that described by Barer and Weinstein; but it does enable an ordinary so-called 'research' lamp to be used for Köhler illumination with medium- and high-power objectives, while if the auxiliary lens is of large diameter it will also illuminate most of the field of low-power objectives.

A bulb treated in this way is also very satisfactory with a field diaphragm as a source for 'critical' illumination, and the grinding process then has the advantage of removing the maker's name and other lettering which would otherwise be liable to appear in the field of view.

Reaction of Stearic Acid Monolayers with Copper and Cuprous Oxide

A number of workers have obtained results which indicate that only a portion of an adsorbed monolayer of stearic acid will react immediately with a copper substrate. (Of course, the reaction is actually with cuprous oxide since, at room temperature in air, all clean copper surfaces rapidly oxidize to cuprous oxide.) Bowden and Moore[1] studied this reaction by putting stearic acid monolayers on radioactive copper and measuring the activity which could be removed by extraction with benzene. They found that when they placed a Langmuir–Blodgett monolayer of stearic acid on a copper surface and allowed it to stand for 18 hr. or heated it, only about 0·14 atom of copper reacts for every molecule of acid in the monolayer. They interpreted this as signifying that their procedure lost 75 per cent of the cupric stearate activity, due to adsorption on their equipment, since reaction was presumed to be complete. Consequently, they adopted an empirical correction factor of 4.

Since the present work was begun, this interpretation was apparently refuted by Beischer's work[2], in which he found that, if radioactive stearic acid is placed on a clean copper surface and the surface is heated until reaction occurs, initially only about 30 per cent of the stearic acid reacts. Here, there can be no possibility of the results being in error due to adsorption on apparatus since, in this technique, unreacted stearic acid is removed and the remaining stearic acid is measured. Therefore, Bowden and Moore are apparently mistaken in assuming that a Langmuir–Blodgett monolayer reacts completely. The molar ratio of copper to stearic acid (0·14–0·30) seems to indicate quite clearly that, in the initial reaction of the Langmuir–Blodgett monolayer, about 30 per cent of the stearic acid reacts to give cupric stearate.

Bowden and Moore's results on the reaction of copper with a benzene solution of stearic acid were difficult to interpret quantitatively in this fashion. Therefore, experiments were carried out to measure the exact extent of the initial reaction of adsorbed monolayers. Clean copper foils were weighed on a microbalance, immersed in a 0·1 per cent solution of stearic acid in benzene, and the excess stearic acid washed off with benzene. After drying, the foils were reweighed, the increment representing the weight of stearic acid adsorbed. The foils were then extracted overnight with benzene in Soxhlet extractors and the extracts analysed for copper using a colorimetric method with sodium diethyl dithiocarbamate[3]. The foils were then weighed again. Since the final weights were equal to the initial weights minus the amount of cuprous oxide removed, the extraction must have removed virtually all the stearic acid and soap.

Analysis of the results indicated that the ratio of moles of copper reacted to moles of stearic acid adsorbed was approximately constant and equal to 0·26 ± 0·04 for varying amounts of adsorbed acid. According to Preston and Bircumshaw[4], when copper is oxidized in air at room temperature, the preferred orientation is for the (111) plane of the cuprous oxide to be parallel to the metal surface. In this plane, there is one copper atom for every 7·8 $A.^2$. Since the cross-sectional area of stearic acid in a monolayer is 21·0 $A.^2$, each stearic acid molecule adsorbed on the cuprous oxide surface should have about 2·6 copper atoms available to it for chemical reaction. Even if one takes planes at somewhat different angles, the amount of copper per unit area will be at least enough to furnish a copper atom for each stearic acid molecule. It is therefore difficult to understand why only about one-quarter of the adsorbed stearic acid reacts, since thermodynamic calculations indicate that complete reaction should occur.

Of course, other planes will be exposed, and these may contain no copper atoms at all or may vary greatly in their rates of reaction with the monolayer. At present, however, no really satisfactory explanation of this phenomenon is available.

It is also of interest to see if copper itself will react with adsorbed stearic acid. Tingle[5] has shown that when a copper surface is cut under a 1 per cent solution of lauric acid in paraffin oil, the fresh metal surface has a high coefficient of friction, which indicates that no reaction takes place. The previous experiments were repeated under an atmosphere of hydrogen, using copper foils which had been reduced in hydrogen at 450° C. Blanks were run in the same way, merely omitting the copper foil. Application of the *t* test to the results indicated that there was no significant difference between the blanks and the runs with copper. Thermodynamic calculations confirmed that metallic copper should not react with stearic acid in a non-oxidizing atmosphere.

We are indebted to Dr. E. A. Gulbransen for illuminating discussions on surface oxides. A full account of this work will be published elsewhere.

[5] Tingle, E. D., *Nature*, 160, 710 (1947).

The interesting results on partial reaction of the monolayer quoted by Dobry and Mahncke are of general interest and do in fact support the earlier observations of Bowden and Moore[1]. Even allowing for the factor of 4, they found that with copper surfaces immersed in a benzene solution of stearic acid the initial reaction was very slow, and after an immersion time of 5 min. considerably less than a single monolayer of soap was formed (see their paper, footnote p. 904). After prolonged immersion, chemical attack was quite heavy and corresponded to the reaction of several molecular layers. Results of this type obtained with layers adsorbed from solution are probably more significant than those obtained with layers deposited from the Langmuir trough. The latter are often unstable and tend to collapse; they appear to form bridges over the surface irregularities so that the area of molecular contact may be

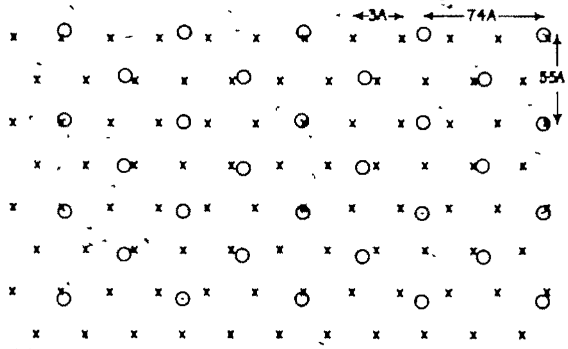

Fig. 1. Approximate lattice arrangement: ×, copper atoms in (111) face of copper oxide; ○, fatty acid molecules in basal plane of fatty acid lattice

considerably smaller than the area of coverage. With layers adsorbed from solution this is not so, though as Daniel[2] and Hirst and Lancaster[3] have pointed out, dilute solutions themselves may give less than a complete adsorbed monolayer.

The difficulty of obtaining effective chemical reaction between adsorbed fatty acids and metal oxide surfaces has also been observed by Tingle[4], by Hirst and Lancaster[5] and Lancaster and Rouse[6]. In general, the presence of water facilitates reaction, and it may be that the non-reactivity of reduced copper surfaces described by Dobry and Mahncke is due to this effect, rather than to the supposed absence of any oxide on the surface.

The main observation that only about one-quarter of the adsorbed fatty acid molecules on a copper surface react (although there are numerous copper atoms available for complete reaction) could be explained as a steric effect. The copper atoms in the 111 face of the cuprous oxide crystal constitute a regular hexagonal array (crosses, Fig. 1) while the molecules in the basal plane of the fatty acid form a face-centred rectangular array (circles, Fig. 1). If an attempt is made to fit these lattices, it is found that the best fit (over a limited area) corresponds to the arrangement in Fig. 1 where only one out of every three rows of acid molecules is close to a copper atom. Thus if the surface consists of small cuprous oxide crystals and the acid is adsorbed as a close-packed film possessing limited mobility at room temperature, only 33 per cent of the molecules would be able to react. With prolonged immersion (or on heating), diffusion of the reacted molecules would enable further reaction to occur. This explanation must be treated very tentatively since the solid surfaces are by no means atomically smooth, and in addition adsorbed long-chain monolayers often have appreciable mobility even at room temperature. If, however, this mechanism is valid, one might expect a different behaviour with other types of metal oxides. On the other hand, if, as the work of Hirst and Lancaster[5] suggests, the observation is mainly due to the effect of minute quantities of moisture on the surface or in the reagents, controlled experiments should readily reveal this.

Trapped Atoms and Radicals in a Glass 'Cage'

THE preparation of highly reactive free radicals and atoms in non-equilibrium concentrations high enough for their direct observation by physical methods has hitherto depended on the use of special rapid techniques such as that of flash photolysis. Here we describe a general method for the preparation of these species under conditions which permit their observation at high concentrations for an indefinitely long period of time. The method involves the photolytic dissociation of a substance dissolved in a transparent rigid solvent at very low temperatures. The only related work which we have been able to find is that of Lewis and Lipkin, who showed that certain rather stable radicals, such as triphenyl methyl, could be detected after photolysis of the parent saturated molecule[1].

The essential conditions to be fulfilled if a reactive species, such as an iodine atom, is to be permanently isolated are: (1) diffusion to the vicinity of another atom must be prevented by using a very viscous solvent; (2) reaction with the solvent must not occur; such reactions are usually accompanied by appreciable activation energies and may therefore be avoided by working at a sufficiently low temperature. We have found that both conditions are fulfilled, for most radicals so far investigated, by using glasses formed from a mixture of hydrocarbons or from ether, alcohol and *iso*pentane at the temperature of liquid nitrogen.

The method was first tested in a very simple manner by irradiating a 10^{-3} *M* solution of molecular iodine in a hydrocarbon glass at 86° K., using a conventional high-pressure mercury arc. The absorption spectrum of the iodine molecule occurs at a wave-length considerably less than that corresponding to the energy of dissociation to normal atoms, and it was believed that this energy might be sufficient to allow the atoms to diffuse apart through the rigid solvent by a process of local softening of the glass. Rapid dissipation of this energy would then result in a system of trapped iodine atoms. In complete accordance with this reasoning, we have found that, on irradiation, such an iodine solution becomes colourless throughout the visible and quartz ultra-violet regions of the spectrum and remains so indefinitely at 86° K. On softening the glass, by warming, the colour returns as the atoms recombine.

Further experiments have established that the phenomenon is a very general one. The results of photolysis of a number of other substances in glassy solvents at liquid nitrogen temperatures are summarized below.

(1) *Ethyl iodide.* On irradiation, the spectrum of ethyl iodide decreases in intensity; but no other spectrum appears. On warming, molecular iodine is formed and recooling has no further effect. We conclude that the iodine atoms have been trapped as before, and it seems probable that trapped ethyl radicals were also present.

(2) *Carbon disulphide.* The first four bands of the $v'' = 0$ progression of CS appear at very high intensity after several minutes irradiation and can be observed for many hours. The spectrum is removed instantly on warming and cannot be detected during irradiation of an ordinary solution at room temperatures. In the gas phase, carbon disulphide disappears by polymerization in a few minutes[2].

(3) *Chlorine dioxide*. The spectrum of chlorine dioxide, which is mainly diffuse in the glassy solvent, is rapidly destroyed and replaced by a second diffuse spectrum the position of which agrees exactly with that of the ClO radical[3]. It has been shown[4] that the flash photolysis of gaseous chlorine dioxide results in the formation of ClO, the life-time of which at comparable concentrations to ours is only a few milliseconds.

(4) *Aromatic compounds*. Porter and Wright have recently shown that the gas-phase photolysis of many single-ringed aromatic molecules results in the appearance of transient banded spectra with life-times less than 10^{-4} sec., which are attributed to free radicals such as benzyl[5]. We have observed similar spectra from the same series of compounds for several hours after photolysis in rigid solvents. These spectra vanished completely on warming the glass, and were therefore readily distinguished from the spectra of permanent products.

In all these examples the spectra were observed, with undiminished intensity, several hours after photolysis; they were removed by softening the glass and did not reappear on cooling.

This method should have many applications. It may be used for trapping the primary products of photochemical or radiation chemical processes for identification. It makes possible the measurement of properties such as infra-red spectra of free radicals, which has not hitherto been possible owing to the need for rapid recording. Bearing in mind the possibility of using still lower temperatures and other solvents, the method should be applicable to practically all free radicals which can be produced by photolysis.

Full details of our techniques and results will be submitted for publication in the *Transactions of the Faraday Society*. One of us (I. N.) is grateful to the Fulbright Commission for a fellowship during the tenure of which this work was carried out.

Anhydrous Trifluoroacetic Acid as a Solvent for Proteins

IT has recently been reported[1] that liquid anhydrous fluoride is a powerful solvent for a wide variety of proteins. It has now been found that the lower perfluoro-aliphatic carboxylic acids possess solvent properties for proteins very similar to those of hydrogen fluoride. Thus it has been observed that trifluoroacetic acid (m.p. − 15·6° C., b.p. 72° C.) readily dissolves the proteins lysozyme, ribonuclease, trypsin, pepsin, crystallized egg albumin, bovine plasma albumin, bovine plasma globulin, edestin, peanut protein globulin, casein, zein, urease, uricase, blood fibrin, insulin, silk fibroin, hide collagen and rat-tail tendon. Solutions in the concentration-range 20–30 mgm./ml. of the above proteins can easily be prepared at 25° C. Solutions of proteins in trifluoroacetic acid prepared *in vacuo* are clear and colourless; on exposure to air, a purple colour develops. Cytochrome *c*, hæmoglobin and catalase are also soluble; solutions of these iron-containing proteins are browner in colour than are the corresponding solutions in hydrogen fluoride.

The physical properties of trifluoroacetic acid are such that dissolved proteins can be readily recovered either by direct evaporation or by lyophilization. Of the proteins listed above, ribonuclease, bovine plasma albumin, trypsin, lysozyme, insulin, cytochrome *c*, hæmoglobin, hide collagen and rat-tail tendon are recovered in a water-soluble condition. Recovered bovine plasma albumin dissolves readily in distilled water; the *p*H of such a solution can be adjusted to neutrality without precipitation of protein, and the recovered material yields a pattern on ultracentrifugation identical with that of the starting material. Cytochrome *c* recovered from trifluoroacetic acid gives a typical ferricytochrome spectrum in aqueous solution; this solution can readily be reduced to ferrocytochrome *c* with sodium hydrosulphite. Cytochrome *c* recovered from hydrogen fluoride, on the other hand, although still water-soluble, can neither be oxidized nor reduced.

Perfluoropropionic and perfluorobutyric acids behave like trifluoroacetic acid except that proteins are dissolved at a much slower rate, especially by perfluorobutyric acid. The lower perfluoro-aliphatic carboxylic acids are all reasonably volatile and can be handled in ordinary glass apparatus. They therefore pose much less serious experimental problems than does the manipulation of hydrogen fluoride. The experiments described here were all carried out on a conventional glass vacuum line with the solvents transferred by vacuum distillation.

As in the case of hydrogen fluoride, these media lend themselves to the carrying out of chemical reactions on proteins, and reactions on proteins using nitrogen dioxide, hydrogen peroxide and trifluoroacetic acid anhydride, as well as other reagents have been carried out. It has further been observed that hydrogen fluoride and trifluoroacetic acid are miscible in all proportions with each other and with sulphur dioxide in the liquid phase. While most proteins are substantially insoluble in pure liquid sulphur dioxide, mixtures of sulphur dioxide and hydrogen fluoride, or sulphur dioxide and trifluoroacetic acid are very good solvents, even when the sulphur dioxide is present in large excess. These mixed solvent systems may be of special interest in protein fractionations and in the study of other high polymeric materials.

A detailed description of these experiments is being prepared for publication elsewhere.

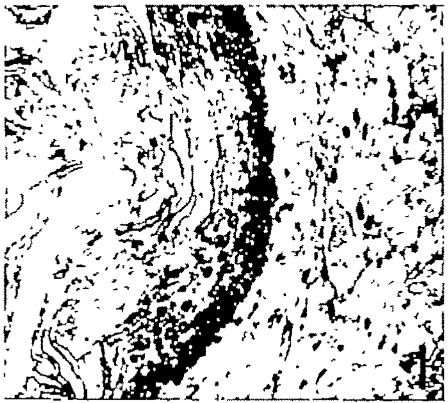
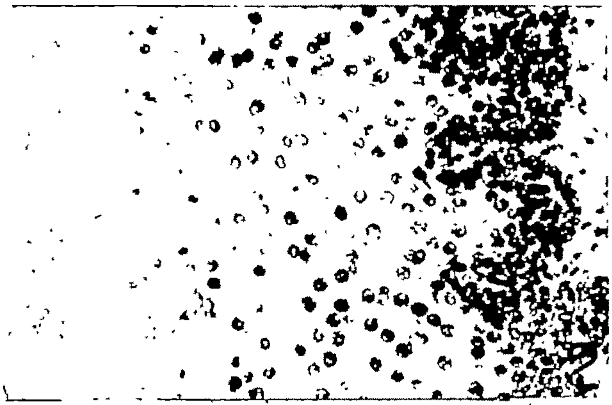
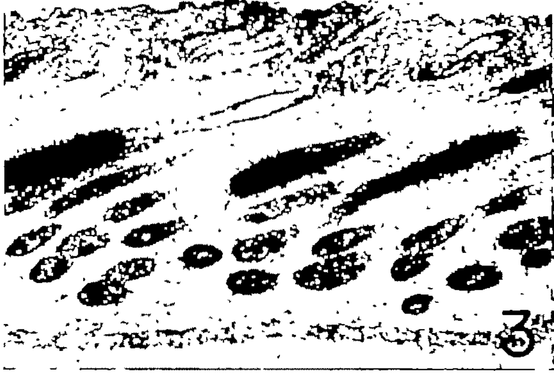
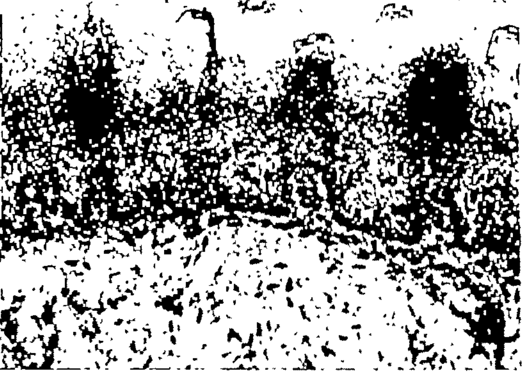
Histology and Chemistry of Keratin Formation

KERATINIZATION, by the holocrine transformation of epithelial cells, occurs normally in the mammalian epidermis, œsophagus, œstrous vagina, and thymic corpuscles. It accompanies abnormal epithelial transformations after œstrogen administration (in genital organs), in vitamin A deficiency, consequent to trauma (including radiation), and in certain cancers. The etiology of keratinization, which represents differentiation by organized cell deaths,









(1) Transverse section through oesophageal wall of dusky-footed wood rat (*Neotoma fuscipes*) Note distinct stratum granulosum Hæmatoxylin and eosin × 175.

(2) Transverse section through oesophageal wall of mountain beaver (*Aplodontia rufa*). Note absence of keratohyalin. Hæmatoxylin and eosin × 175.

(3) Radioautograph of sagittal section of mouse belly skin showing hair follicles in anagen. Note concentration of radiocystine in keratogenous zone 8 hr after injection Emulsion coating. Hæmatoxylin and eosin, prestained × 70

(4) Radioautograph of conical papillæ of mouse tongue in transverse section. Note concentration of radiocystine above dermal papilla (base of spine) 8 hr. after injection. Emulsion coating Hæmatoxylin and eosin, post-stained. × 175

remains unknown; however, the suggestion that a local lack or inactivation of vitamin A is responsible is a possibility[1,2].

A principal obstacle to our understanding of the mechanism of keratin formation is the lack of correlation between morphological and biochemical knowledge of the process. The significance and reality of the organelles in keratinizing cells are still being debated. Recently, Medawar[3] has termed artificial the tonofibrils and the intercellular bridges, hitherto two of the best-established microstructures of the mammalian epidermis (and of keratinizing epithelia generally). While his interpretation of the intercellular 'bridges' as really intracellular structures seems justifiable, these areas do represent definite contact points between adjacent cells. Changes in these areas associated with the growth-rate of epidermis are indicated in the electron microscopic studies of von Albertini[4]. We have seen[5,6] alterations with acanthosis following topical application of vitamin A similar to those occurring in the initial phases of carcinogen-induced hyperplasia[4], wherein the cells are closely applied to each other, the intercellular spaces disappear and the 'bridges' are reduced to desmosomes.

Little evidence remains to indicate that the keratohyalin granules of the classical histologist are keratin precursors, as was originally supposed. Leuchtenberger and Lund[7] have shown that granules containing ribonucleic acid occur in the stratum granulosum region of human and dog epidermis, and we find such granules to be distributed extensively even in the thin rat epidermis, although they appear considerably different from those seen with routine histological stains. In addition, whereas ribonuclease treatment results in the disappearance of azurophilic granules from the normal rat epidermis, it does not affect the appearance of the hæmatoxylin-staining granules (cf. Montagna[8]). Thus, the keratohyalin granules may consist only in part of ribonucleic acid, as Leuchtenberger and Lund suggest[7], or conceivably the keratohyalin and the azurophilic granules are different entities. No granules are seen with the Bennett or Barrnett–Seligman methods for protein-bound sulphydryl groups[6,9–11]. It is difficult to conceive of the significance of keratohyalin in terms of cytoplasmic basophilia associated with protein synthesis. Acanthosis of the nipple epidermis of the guinea pig involves a striking increase in keratohyalin whether accompanied by hyperkeratosis (after œstrogen treatment) or presumed hypokeratinization (after vitamin A treatment)[6].

Leblond[12] has pointed out that 'hard' keratin, such as occurs in nails and in the cuticle and cortex of hair, can be distinguished from 'soft' keratin by the absence of keratohyalin, the adhesion of the cells, the lower lipid content, and the higher sulphur content. That the presence of keratohyalin always characterizes 'soft' keratinization may be questioned. A stratum granulosum is a constant feature of the œsophagus of many rodents (rat, mouse, guinea pig, gopher, several cricetids, etc.); in the mountain beaver (*Aplodontia rufa*) and the fox squirrel (*Sciurus niger*): however, the granular layer is absent (Figs. 1 and 2) (cf. Goetsch[13]). This is also true of the œsophagus of man and carnivores, where the process can be described as parakeratotic, resulting in the sloughing of cells with pycnotic nuclei. In the mountain beaver and squirrel, however, the sloughing layers remain temporarily as true 'soft' keratin, just as in other rodents. Eisen *et al.*[10] question the distinction between 'soft' and 'hard' keratinization and consider the latter to represent parakeratosis, evidently ignoring its characteristic 'non-scurfiness' (cf. Medawar[3]).

It might be expected that an active synthesis of keratin, such as Biggers[14] postulates for the œstrogen-treated vagina, would involve a specific uptake of cystine and other sulphur-containing amino-acids. Radioautographic and tracer studies of mouse vaginal epithelium now in progress[15] do not indicate an uptake of cystine labelled with sulphur-35 in œstrogen-induced keratinization appreciably different from that in androgen-induced mucification (in both instances cell proliferation and protein synthesis are involved). However, during the active growth phase (anagen) of mouse hair, high activity of the keratogenous zone of the hair follicle is seen 8 hr. after administration of radiocystine (Fig. 3). The 8-hr. radioautograph parallels almost exactly the published figures of localization of sulphydryl[10,16].

The conical papilla of the mouse tongue presents an interesting picture in that it consists of a core of 'hard' keratin projecting posteriorly, covered on its anterolateral surfaces by a sheath of 'soft' keratin. The 'hard' keratin (readily distinguished by its refractoriness to eosin staining and its affinity for picric acid) arises from a keratohyalin-free area at the apex of the small dermal papilla. Eight hours after administration of radiocystine, this region is highly radioactive, in contrast to the limited activity in the adjacent 'soft' keratin-forming epithelium (Fig. 4). The concentration of cystine by 'hard' keratin-forming structures may reflect specific uptake by keratogenous zone cells for the synthesis of keratin or 'capture' by rapidly proliferating cells of the cystine which is not turned over once the living cells keratinize. Work in these areas is being continued.

This investigation was aided in part by cancer research funds of the University of California.

Biosynthesis of *l*-Ascorbic Acid

THE rat is known to synthesize ascorbic acid in the course of its normal metabolism. It has been observed by Longenecker and associates[1] that this synthesis can be greatly stimulated, resulting in the high urinary excretion and tissue reserve of the vitamin, when the rats are given daily a variety of compounds, particularly narcotics like chloretone. It has been previously reported in several communications[2-6] from this laboratory that the high urinary excretion of ascorbic acid stimulated by chloretone can be completely suppressed, if the animals are made deficient in thiamine, riboflavin, pantothenic acid or folic acid. This action of the narcotic can be restored by correcting the respective deficiency with the particular vitamin. The effect of inanition has been taken into account by pair-feeding the experimental animals. The excretion under chloretone is unaffected by adrenalectomy or pancreatectomy of the rats. A definite inhibition of pyruvic acid oxidation by brain tissue of the rat has been observed in presence of chloretone under aerobic condition. The high urinary excretion of ascorbic acid stimulated in the rat under chloretone can also be almost entirely suppressed by the daily administration of either adenosine triphosphate, malic acid or thyroxine in suitable doses. The effect of chloretone is promptly restored when the administration of these compounds is stopped. Other compounds, such as adenosine diphosphate, adenylic acid, dinitrophenol, glutathione and dicarboxylic acids such as oxaloacetic, fumaric and succinic, have been tried without any such suppressive effect on the urinary excretion of ascorbic acid by the narcotized rat.

With the inhibition of pyruvic acid oxidation under chloretone there is a simultaneous decrease in the phosphorus esterification by the brain tissue of the rat. Relative to oxygen consumption, the phosphorylation of that tissue decreases considerably in the presence of chloretone. In the chloretonized condition, the inorganic phosphorus-level in the liver tissue of the rat is appreciably raised, while the adenosine triphosphate phosphorus, hexose-phosphates and triose-phosphates determined both by the chemical and the paper chromatographic methods are considerably diminished, the lowest value being obtained in the case of phosphopyruvic acid. The tissue reserves of these intermediary phosphorylated compounds can be restored to normal levels by the administration of adenosine triphosphate or malic acid or thyroxine in spite of the administration of chloretone being continued simultaneously. We have previously suggested[6] that pyruvic acid might be a precursor for the synthesis of ascorbic acid by the rat. The results of some *in vivo* experiments by Ghosh[7] from this laboratory lent additional support to this view. He showed that pyruvic acid administration increased the ascorbic acid excretion by the chloretonized rat. It has now been observed that by incubating liver tissue with sodium pyruvate under suitable conditions, an increase of 15–20 per cent in the ascorbic acid content occurs over that without the added substrate. This increase becomes more than 30 per cent, if the incubation is carried out in presence of thiamine.

Further evidence in support of these findings has been obtained by the use of the tracer technique. By administering labelled pyruvamide ($CH_3{}^{14}COCONH_2$) to rats under chloretone, it has been possible to separate in a pure and crystalline form both radioactive ascorbic acid and the 2 : 4-dinitrophenyl hydrazine derivative of dehydroascorbic acid from the urine of the experimental animals[4]. In this separation, column chromatography with Brockmann alumina or ion-exchange resin as adsorbing material has been used. The purity of the ascorbic acid isolated and its derivative has been established by chemical analysis and also by absorption-spectra measurements. The ascorbic acid and its derivative gave 315 and 110 counts per min. per mgm. of the compound respectively with a Geiger–Muller counter.

After administration of the isotopic pyruvamide to the chloretonized rats, the following intermediary compounds were separated from the liver tissue of the treated rats by paper chromatographic technique: glucose-1-phosphate, glucose-6-phosphate, fructose-1-6-phosphate, *dl*-glyceraldehyde phosphate, dihydroxyacetone-phosphate, 3-phosphoglyceric acid, and phosphopyruvic acid. Radioautographs of the different compounds have been prepared by the method of Benson *et al.*[8] by prolonged exposure of the paper containing the individual compound to the X-ray film and developing the latter for the radiation study. It has been observed that none of the phosphorylated intermediaries studied had incorporated any carbon-14 in their respective molecules. By the application of the same techniques and from the same liver tissue either treated or hydrolysed, as the case may be, it has been possible to separate the citric, α-ketoglutaric, succinic, fumaric and malic acids of the Krebs cycle and also fifteen amino-acids. The radioautographs of these acids indicate that no carbon-14 had been incorporated into any of them. Glycogen isolated in pure form from the same liver tissue gave an activity of 70 counts per min. per mgm.

It would appear from the above that pyruvic acid lends itself to the synthesis of ascorbic acid in the chloretonized rat. The exact pathway of this synthesis requires further exploration.

We are indebted to Prof. B. D. Nag Chaudhuri and Mr. B. Bose of the Institute of Nuclear Physics, Calcutta, and to Dr. D. P. Burma of the Bose Research Institute, Calcutta, for their help, and to Prof. M. Calvin and Dr. A. A. Benson of the Radiation Laboratory, University of California, for gifts of some of the phosphorylated intermediary compounds used for comparison. One of us (S. C. R.) is indebted to Dr. E. S. G. Barron and Dr. R. Redfield of the School of Medicine, Chicago, for their kind co-operation in the preliminary investigation of the problem with labelled pyruvamide. Acknowledgment is made to the Indian Council of Medical Research for financing this work. One of us (N. C. G.) is indebted to the Ministry of Education, Government of India, for a scholarship.

Metabolism of Elastin in the Adult Rat

The fully formed collagen fibrils of connective tissue in adult animals are known to have a very slow rate of metabolic turnover[1]. Recently, evidence has been presented for the existence of a soluble precursor of collagen of high turnover-rate[2]. By contrast, I have been unable to find any published information about the metabolism of elastin—another important connective-tissue protein which is a major constituent of the larger arteries and certain spinal ligaments. The following experiments were therefore conducted to supply some information on elastin metabolism.

In view of the high glycine content of elastin, and since carbon-14 labelled glycine had been used in the experiments on collagen metabolism referred to above, (α-^{14}C)-glycine, injected intraperitoneally in a dose of 10 μc. per 100 gm. body-weight, was used in these experiments. The rats used were all adult males and were in two groups of twelve rats each. The first group were normal rats killed in two lots of six at one day and nine days after injection of the labelled glycine. The second group were rats with atrophy of the right hind-limb produced by operation six weeks previous to receiving the labelled glycine[3]. These were also killed in two lots of six rats, one day and nine days after injection of (α-^{14}C)-glycine. On killing, the aortæ were dissected out from the heart down to the bifurcation of the common iliacs and pooled in lots of three or six to ensure a sufficiency of material. Elastin was separated and purified according to Tunbridge and co-workers, who state that this method appears to give homogeneous preparations on examination by electron microscopy[4]. Although our material has not been examined in this way, the morphology and staining characteristics suggest that the preparation consisted of pure elastin. Crystalline glycine samples from hydrolysates of the elastin were separated by column chromatography as the dinitrophenyl derivative and the radioactivity determined on solid samples[5].

RADIOACTIVITIES OF DINITROPHENYL-GLYCINE PREPARED FROM ELASTIN OF AORTÆ OF RATS WHICH RECEIVED (α-^{14}C)-GLYCINE BY INTRAPERITONEAL INJECTION

	No. of rats used	Interval between injection and killing (days)	Radioactivity of DNP-glycine (counts/min./sq cm ('infinite thickness'))	Total wet weight of aortæ (gm)	Weight of DNP-glycine recovered (mgm.)
Normal	6	1	175	1 26	66
	3	9	153	0 71	37
	3	9	186	0 57	29
Operated	6	1	169	1 38	55
	3	9	191	0 68	32
	3	9	142	0 61	23

The radioactivities found in glycine derived from elastin of the aortæ of the normal and operated rats are shown in the accompanying table. It will be seen that there is no significant fall in specific activity with time in the elastin glycine from either normal or operated rats. Indeed, all the observed counts are very similar, and are of the same order as those found previously in adult bone collagen[1,3]. Although the time interval of this experiment is not very long, it is long enough to have allowed demonstration of an active metabolic turnover in elastin if indeed this did occur in adult rat aorta. It therefore seems probable that in the adult rat elastin, in common with the major portion of collagen, has a very slow rate of metabolic turnover.

Enzymatic Conversion of Two Geometrical Isomers into Enantiomorphs

MUCONIC acid is an intermediate in the oxidation of certain aromatic compounds by bacteria. It is formed enzymatically by an oxidative ring cleavage from catechol[1], and is then re-arranged to β-ketoadipic acid, which cannot be further degraded by the cell-free extracts. Evans, Smith, Linstead and Elvidge[2] studied the action of crude cell-free bacterial extracts on the three isomers of muconic acid, and found that only the *cis-cis* isomer could be converted to β-ketoadipic acid. They also tested the ability of extracts to attack certain lactones related to the muconic acids, and demonstrated that γ-carboxymethyl-Δ^{α}-butenolide could be rapidly converted to β-ketoadipic acid. On the basis of these findings they postulated the reaction sequence shown in Fig. 1.

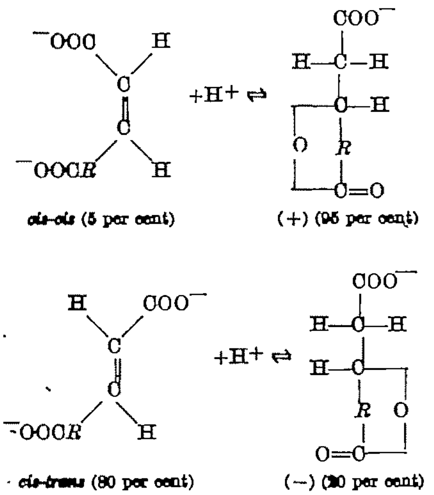
Fig. 1. Mechanism proposed by Evans *et al.* (ref. 2) for conversion of catechol to β-ketoadipic acid

From extracts of *Pseudomonas fluorescens* we have isolated a lactonizing enzyme which converts *cis-cis*-muconic acid to γ-carboxymethyl-Δ^{α}-butenolide, and a delactonizing enzyme which converts this lactone to β-ketoadipic acid, thereby confirming the reaction mechanism postulated by Evans *et al.*[2]. The details of the work will be described elsewhere, and the main purpose of the present communication is to direct attention to a remarkable pair of reactions catalysed by the lactonizing enzyme.

When γ-carboxymethyl-Δ^{α}-butenolide is formed from *cis-cis*-muconic acid, a centre of asymmetry is established at the γ-carbon atom. Consequently, the chemically prepared lactone[2] is a racemic mixture. The lactone prepared enzymatically from *cis-cis*-muconic acid is the (+)-lactone ($[\alpha]_D = +53\cdot2°$). Since whole cells and also the delactonizing enzyme are stereospecific for the (+)-lactone, the unnatural (−)-lactone can be simply prepared by allowing a cell suspension to act upon the synthetic lactone. By these means we were able to obtain both isomers of the lactone.

The lactonizing enzyme catalyses a freely reversible interconversion of *cis-cis*-muconic acid and the (+)-lactone. At pH 8·0, the equilibrium mixture contains 95 per cent lactone. The *trans-trans* isomer of muconic acid is not attacked; but the *cis-trans* isomer can be decomposed at a rate about 0·02 per cent of that with the natural substrate. Moreover, the (−)-lactone can be substituted for the (+)-lactone in a back reaction. Further study has established the fact that the lactonizing enzyme can catalyse a second reversible reaction, parallel to the natural reaction, which results in the interconversion of *cis-trans*-muconic acid and the (−)-lactone, but cannot interconvert the two geometrical isomers or the two enantiomorphs. At pH 8·0 the equilibrium mixture of *cis-trans*-muconic acid and (−)-lactone contains 20 per cent lactone. From the equilibrium constants of the two parallel enzymatic reactions, the free energy change for the *cis* → *trans* isomerization can be calculated; it is − 2·5 kcal., a value which agrees with the known chemical properties of the two isomers and is within the range recorded for similar isomerizations.

Since the double bond in the lactone ring has a *cis* configuration[2], it is evident that the lactonizing enzyme must act upon the *trans* bond of *cis-trans*-muconic acid. The essential features of the two reactions which it catalyses are shown in Fig. 2. It seems clear that the basis of this pair of reactions is an ability of the enzyme to distinguish between two chemically identical atoms or bonds. Thus in the forward reaction, only one of the two component bonds of the γ-δ double bond is split; and in the back reaction only one of the two δ-hydrogen atoms is removed. The ability of an enzyme to distinguish between chemically identical groups has been demonstrated in the dehydration of citric acid[4] and the oxidation and reduction of diphosphopyridine nucleotide by alcohol dehydrogenase[5]; a three-point attachment of substrate to enzyme has been proposed as the mechanism for this discrimination. Fig. 3 shows graphically how such a mechanism would apply in the present case. For simplicity, the drawing shows only those regions of the molecules concerned with the stereoisomeric changes. The following arbitrary restrictions are imposed: (*a*) when the double bond is attacked, only the lower bond is opened, and (*b*) in the removal of *HB* only the right-hand hydrogen is removed.



cis-cis (5 per cent) (+) (95 per cent)

cis-trans (80 per cent) (−) (20 per cent)

Fig. 2. The two reversible reactions catalysed by the lactonizing enzyme, $R = -CH{=}CH-$. The equilibrium values shown are for pH 8·0

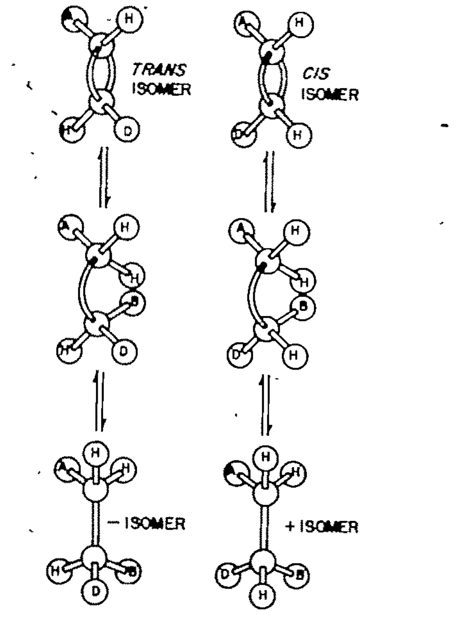


Fig. 3. A three-dimensional diagrammatic representation of the reactions catalysed by the lactonizing enzyme

Krebs[6] has postulated that the formation of L-malic acid from fumaric acid by fumarase involves a similar mechanism. Fumarase apparently cannot catalyse the 'unnatural reaction', maleic acid → D-malic acid; this is not surprising, since the structural difference between maleic acid and fumaric acid is much greater than that between *cis-cis* and *cis-trans*-muconic acids.

Cell Activity and Deoxyribonucleic Acid Content of the Nuclei of the Thyroid Gland of the White Rat

Recently, it has been claimed that the deoxyribonucleic acid content of the interphasic nuclei in the different tissues corresponds, for a given species, to a value which is double that for the deoxyribonucleic acid content of the spermatic nuclei of that same species. Nevertheless, some exceptions were observed, namely, by L. Lison and J. Pasteels, J. Govaert, C. Leuchtenberger and A. Schrader[1], and lead to the hypothesis that this 'theoretical diploid value' would only be an equilibrium value, from which the deoxyribonucleic acid content would vary more or less widely as a function of the cell activity.

From this point of view, we have carried out some experiments on the thyroid gland of the white rat. It is easy to influence the activity of the cells of this organ and to control histologically its physiological state[2]; and it is well known that the activity of the thyroid cell can be inhibited by thyroxine and stimulated by thiouracil. On histological examination, the physiological states are represented on one hand by the endotheloid aspect, on the other by the columnar aspect of the cell.

Fifteen white male rats aged six to seven months were used. A first group of five rats served as controls; a second group received daily during seventeen days an intramuscular injection of 0·1 mgm. thyroxine; a third group received daily, by gastric probe, and during the same period a dose of 20 mgm. propylthiouracil. All the rats were killed at the same time. The thyroids were quickly removed and fixed in a mixture of alcohol (96°, 75 parts), formalin (40°, 20 parts) and acetic acid (5 parts) as well as a testicle of a control rat. All the manipulations of dehydration and embedding were performed simultaneously. The sections (10 microns) were placed on the same slide and treated by the Feulgen reaction. The deoxyribonucleic acid content of each nucleus was measured with Lison's histophotometer. The extinction coefficient obtained in the wave-length region 5200–5400 A., multiplied by the projection area, gives in arbitrary units the relative value of the deoxyribonucleic acid content. Details of this technique have been given by L. Lison[3].

In every thyroid gland we measured a hundred nuclei. The results of the statistical computations for each rat are shown in Table 1. We noted some haploid and doubly charged nuclei, probably prephasic[4]. For the present computations we took into consideration only the diploid nuclei; this explains why the number of measured nuclei was sometimes less than 100. The mean value for the spermatocytes I being at 1,934, the theoretical diploid value will be at 967 arbitrary units.

Table 1

Spermatocytes I		n	$\bar{x}$	$S_{\bar{x}}$	S
		100	1,934	± 15·5	155·4
Controls	Rat 52	93	825	± 22·8	220·4
	Rat 53	87	827	± 15·0	140·2
	Rat 54	87	828	± 17·0	159·4
	Rat 55	97	830	± 23·2	229·1
	Rat 56	79	817	± 20·4	181·1
Thyroxine	Rat 57	97	747	± 18·5	182·3
	Rat 58	98	700	± 18·7	185·9
	Rat 59	94	758	± 18·7	179·0
	Rat 60	94	732	± 19·9	193·0
	Rat 61	100	557	± 14·6	146·4
Thiouracil	Rat 62	92	877	± 16·7	160·4
	Rat 63	98	838	± 16·9	167·6
	Rat 64	100	906	± 17·6	176·4
	Rat 65	98	825	± 16·5	163·8
	Rat 66	92	948	± 23·8	228·6

n, Number of measurements; $\bar{x}$, mean value; $S_{\bar{x}}$, deviation of the mean; S, standard deviation.

The mean values of the five controls (rats 52–56) are statistically very constant but obviously less than the diploid value.

The mean value of the five rats receiving thyroxine (rats 57–61) is reduced by 10 per cent and even, for one, by 32 per cent. This marked decrease cannot arise from a technical error, as the mean, itself, arises from a hundred consistent measurements.

On the other hand, the mean value of the five rats receiving thiouracil (rats 62–66) shows a clear tendency to increase.

In order to demonstrate more clearly these variations, we pooled all the measurements in each group; Rat 61 was not included, since its mean value was not 'consistent' with the four other rats of the same group (Table 2).

Table 2. POOLED RESULTS

	n	$\bar{x}$	$S_{\bar{x}}$	S
Controls	443	884	± 8·6	179·7
Thyroxine	383	737	± 9·4	185·0
Thiouracil	480	879	± 8·4	185·8

By 'Student's' t-test we have demonstrated that the observed variations are highly significant (Table 3).

Table 3. t-TEST

	t	P
Controls/thyroxine	7·5	< 0·001
Controls/thiouracil	3·7	< 0·001
Thyroxine/thiouracil	11·0	< 0·001

By these experiments we have demonstrated the existence, in the thyroid of the white rat, of a correlation between the variations in cell activity and the deoxyribonucleic acid content of the nuclei; the deoxyribonucleic acid increases with stimulation of cell activity and decreases with inhibition of cell activity. The deoxyribonucleic acid content of the thyroid of normal rats, and especially those with thyroxine-inhibited thyroids, is markedly below the diploid value; on the other hand, in the stimulated thyroid, the content of deoxyribonucleic acid reaches, approximately, the theoretical diploid value.

This investigation was aided by a grant from the Belgian National Foundation for Scientific Research.

Composition and Action of Yeast Polygalacturonase

YEAST polygalacturonase is an exo-cellular pectic enzyme produced by *Saccharomyces fragilis* in a synthetic, protein-free medium. The enzyme is constitutive and is not accompanied by pectinesterase[1]. When it is allowed to act on pectic acid, the following series of reactions occurs[2]:

(a) Pectic acid → penta- + tetra- + tri- + digalacturonic acids;

(b) Pentagalacturonic acid → tetra- + galacturonic acids;
Pentagalacturonic acid → tri- + digalacturonic acids;

(c) Tetragalacturonic acid → tri- + galacturonic acids;

(d) Trigalacturonic acid → di- + galacturonic acids.

Reactions (a) and (b) comprise the initial rapid linear phase of the hydrolysis. The optimum pH of (a) is 4·4. A slower linear phase, beginning at 25 per cent hydrolysis, is characterized by reaction (c) which is optimal at a pH of approximately 3·5. After about 50 per cent hydrolysis, (d) is the main reaction, and it occurs at a very low rate. Finally, after 70 per cent hydrolysis, the reaction ceases, leaving the dimer and monomer as end products. Reaction (d), like (c), is much slower at the higher pH; hence at pH 4·5, the reaction appears to cease at 50 per cent hydrolysis and the apparent end products are tri-, di- and galacturonic acids[3].

In view of the postulations of Dingle *et al.*[4] and Schubert[5] which suggest that several polygalacturonase components occur in mould pectic enzymes, the nature of yeast polygalacturonase was studied.

We have found that yeast polygalacturonase of the crude culture liquid can be adsorbed in the cold on a pectic acid gel at pH 3·0 and eluted with 1 N acetate buffer at pH 5·0. This resulted in a 13-fold concentration, but only in a negligible increase in specific activity. An electrophoretic analysis was performed after further concentration by precipitation with saturated ammonium sulphate followed by dialysis. The pattern indicated two components. The major one comprised about 95 per cent of the total protein. A variable solvent solubility test also indicated two fractions. At 4° C., the minor fraction was precipitated at 0·2 ammonium sulphate saturation and the major one was salted out between 0·8 and complete saturation. A specific property solubility test based on the procedure of Falconer and Taylor[6] showed that only the major fraction had yeast polygalacturonase activity. The specific activity of this fraction, calculated by the last method, was 0·179 yeast polygalacturonase unit per mgm. protein (1 unit of activity releases 1 mM of reducing groups per min. at pH 5·0 from a 0·5 per cent pectic acid solution). The material which was precipitated between 0·75 and complete saturation moved as a single boundary in the ultra-centrifuge.

The rates of yeast polygalacturonase activity on tri-, tetra- and poly-galacturonic acids were compared, using the filtrates obtained at four different concentrations of ammonium sulphate. The ratios of activity remained roughly constant during the salting out, indicating that the hydrolysis of pectic acid to the digalacturonic acid stage is catalysed by a single enzyme. Full details of this work will be published elsewhere.

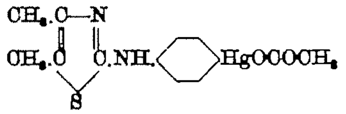
Use of Mercurated Thiazoles as Fungistatic Agents

In the course of our studies on methods of synthesis of thiazole derivatives and their possible useful applications, it appeared of interest to examine their fungicidal properties, since these contain in a cyclic ring structure the grouping N—C—S which is present in known fungicides like tetramethyl thiuram disulphide, thioureas and thioacetamide. Some new mercurated derivatives of thiazoles have also been prepared by us, and since mercury is a powerful fungicidal element, phenyl mercuric acetate being actually used for such diseases as apple scab, it was considered worth while to test these mercurated thiazoles for their fungicidal action.

The thiazole compounds employed were thirteen new 2-substituted-amino 4-5-dimethyl thiazoles prepared by reaction of ethyl methyl ketone with substituted thioureas in presence of iodine by a modified method already reported by us[1]. These compounds have been mercurated by treatment with mercuric acetate in acetic acid. The position taken up by the acetoxy mercuric group has also been fixed by us[2]. The resulting mercurated thiazoles have been assigned the structure :



All the twenty-six new thiazoles (thirteen unmercurated and the rest mercurated) have been tested. For fungicidal assay, the method of Montgomery and Moore[3] was used. *Alternaria polandui* Ayyangar was used as the fungus indicator.

The unmercurated thiazoles completely inhibited spore germination even at a concentration of 100 parts per million. At 250 p.p.m. the percentage of inhibition was only 25–30 per cent.

The mercurated thiazoles were, however, more powerful, being 100 per cent effective in inhibiting spore germination of the fungus even at a concentration of 2 p.p.m.

Detailed investigations will be published elsewhere.

Glutathione Breakdown and Transpeptidation Reactions in *Proteus vulgaris*

The enzymic breakdown of glutathione by animal tissues has been extensively studied[1]. Both peptide bonds are split by enzymes of rat kidney homogenates ; the γ-glutamyl bond is first hydrolysed to glutamic acid and cysteinylglycine, the latter being afterwards further broken down to cysteine and glycine[2]. In 1950, Hanes, Hird and Isherwood[3] demonstrated that preparations of sheep-kidney not only hydrolysed glutathione, but also catalysed the transfer of the γ-glutamyl residue to the products of hydrolysis and to other added amino-acids. A more detailed analysis of the relative reactivities of various amino-acids with glutathione has recently been carried out[4]. Transpeptidation reactions were also observed between other γ-glutamyl and glycyl peptides and amino-acids in animal and plant tissues[5]. The discovery of such reactions led to speculation on their possible role in the formation of new peptides and of proteins. Although cell-free extracts of *Escherichia coli* synthesize glutathione from its component amino-acids[6], these extracts do not hydrolyse the tripeptide. Breakdown of glutathione and transpeptidation in micro-organisms have not been previously reported ; a study of these reactions in the bacterium *Proteus vulgaris* is described here.

Washed whole-cell suspensions or cell-free extracts of *Pr. vulgaris* (prepared by sonic disintegration) were incubated with glutathione with or without added amino-acids at *p*H 7·4 for 1 hr. at 37°. After deproteinization with ethanol containing N-ethyl maleimide[3], the supernatant was examined for amino-acids and peptides by paper chromatography. Fig. 1 shows a typical chromatogram of the products obtained when *Pr. vulgaris* suspensions or extracts are incubated with glutathione. In addition to the glutamic acid, glycine and small amounts of cysteine expected (cysteine is further metabolized to pyruvate, hydrogen sulphide and ammonia by *Pr. vulgaris*[7]), two new ninhydrin-positive materials with R_F values similar to γ-glutamylglutamic acid and γ-glutamylglycine are produced. The new compounds are increased in amount respectively by the addition of L-glutamic acid or glycine to the original incubation

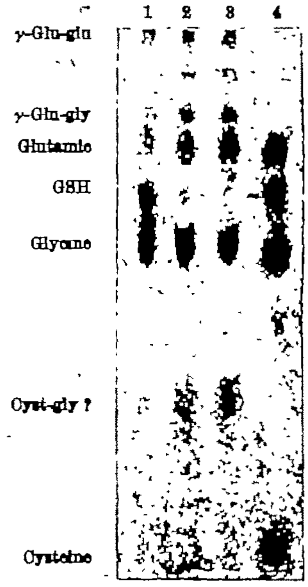

Fig. 1. Descending paper chromatogram showing products of the reaction of *Proteus vulgaris* on glutathione. 1, 2 and 3 represent respectively 7·2, 14·4 and 21·6 mgm. dry weight of organism in phosphate buffer *p*H 7·4 in 0·4 ml. incubation mixture containing 5 μM glutathione. 4 is a control strip of amino-acids and glutathione. Incubations were carried out for 1 hr. at 37°. Whatman No. 3 filter paper developed in propanol–water (80 : 20) for 17 hr. Colour developed by spraying paper with 0·1 per cent ninhydrin in chloroform and heating for 5 min. at 105°

mixtures. Unless high concentrations of the micro-organism are used (of the order of 12 mgm. dry wt./5 μM glutathione), detectable quantities of the new materials are not produced and only small quantities of the component amino-acids of glutathione are observed. The new material obtained when glycine is added to the incubation mixture was eluted and shown to behave like γ-glutamylglycine when compared chromatographically with authentic samples of the α- and γ-peptides. This material was obtained in chromatographically pure form, hydrolysed and shown to contain only glutamic acid and glycine.

Transpeptidation to foreign amino-acids added to the incubation mixture has been likewise observed. New materials corresponding to the γ-glutamyl peptides have been obtained with L-methionine, L-valine, L-phenylalanine, L-leucine and L-glutamine. As with the system from kidney, the quantities of new γ-peptides formed are dependent not only on the amount of acceptor amino-acids present, but also on the particular amino-acids in the system; thus, for example, phenylalanine is more active in transpeptidation than leucine as judged by the intensity of paper chromatographic spots. Using concentrations of acceptor amino-acids up to ten times the concentration of glutathione, increasing the amount of amino-acid increased the amount of γ-peptide formed. The abilities to hydrolyse glutathione and cause transpeptidation remain with the supernatant after centrifugation of the extract for 60 min. at 11,000 *g* and are lost on exposing the extract to temperatures of 55° for 10 min. Of the antibiotics known to interfere with protein synthesis in *Staphylococci*[8], terramycin, aureomycin and chloramphenicol had no effect on transpeptidation at levels of 100 μgm./ml.

These experiments demonstrate the presence in bacterial cells of enzymes catalysing transpeptidations of the same type as in mammalian tissues[3]. Although these exchange reactions appear to be widely distributed in Nature, their significance as a potential mechanism of peptide formation remains uncertain.

Norvaline: a Growth Factor for Excised Tomato Roots

EARLY reports[1] that norvaline, a synthetic amino-acid, was detectable in protein hydrolysates have not been confirmed using modern techniques[2]. No reports are known to me of the detection of norvaline as a free amino-acid in tissues. It has, however, been reported[3] that on addition of α-ketovaleric acid and glutamine to extracts of rat liver, the α-ketovaleric acid was converted to norvaline. A number of other α-keto acids were converted to the corresponding amino-acid by the extract. The conversion to norvaline, therefore, could be attributed to low specificity of the postulated enzyme. In spite of this, it was decided to include DL-norvaline in a series of amino-acids tested for ability to replace pyridoxine in the nutrition of a clone of excised tomato roots. Some nutritional requirements of this clone and the experimental techniques are given elsewhere[4].

Replacement of pyridoxine by norvaline gave approximately 50 per cent of the growth obtained in the presence of pyridoxine. The best concentration was found to be 4×10^{-4} *M* of the free base. A representative result, using this concentration of norvaline, is shown in Table 1.

Table 1. FINAL LENGTH OF MAIN AXIS PER ROOT (MM.) OF EXCISED TOMATO ROOTS GROWN FOR SIX DAYS IN: MEDIUM (1) WITHOUT PYRIDOXINE; (2) WITH PYRIDOXINE; AND (3) WITH NORVALINE REPLACING PYRIDOXINE. MEANS ARE FOLLOWED BY STANDARD ERRORS AND NUMBERS OF REPLICATES IN BRACKETS

Medium	Length of main axis per root (mm.)
1. Minus pyridoxine, minus norvaline	23·1 ± 1·05 (9)
2. Plus pyridoxine, minus norvaline	97·6 ± 4·24 (9)
3. Minus pyridoxine, plus norvaline	62·0 ± 6·09 (9)

This result has been confirmed on separate occasions and using DL-norvaline from two different sources. Paper chromatography of solutions obtained on autoclaving norvaline, either in water or in the medium, did not reveal any substance with an R_F value, or colour (ninhydrin test), different from those of norvaline. The calculated amount of norvaline per spot on the chromatogram was 125 μgm.

The fact that norvaline may act as a growth factor provides tentative evidence that it is involved in 'normal' metabolism. Whether this is so, and the precise relation of vitamin B_6 to norvaline, is being examined.

Succinoxidase Inactivation by a Lecithinase in Barley Seedlings

RECENTLY, several investigators[1–4] have isolated mitochondrial fractions from plant tissues which are similar to animal mitochondria in that they are capable of oxidizing all the known substrates of the Krebs citric acid cycle, concomitantly synthesizing adenosine triphosphate from adenylate and inorganic phosphate. However, the oxidative and phosphorylative capacities of mitochondria from different plant tissues vary considerably. For example, mitochondria from oats show much less activity in the oxidation of Krebs-cycle acids than do those from the mung bean; while mitochondria from mung bean hypocotyls are more effective in oxidative phosphorylation than particles from leaves and roots of the same plant[2,3]. Paquin (unpublished work) in our laboratory has also observed that the mitochondria from tomato leaves are considerably less active in the oxidation of succinic acid than are those from hypocotyls of the same plant, and that this is accompanied by a higher endogenous oxygen uptake in the former as compared to the latter.

In our studies on the enzymic activity of mitochondria isolated from barley seedlings (*Hordeum vulgare* L. var. Montcalm) by the procedure of Millerd *et al.*[1], we have observed that fractions from 4–5 day old seedlings apparently lose the ability to oxidize succinic acid, whereas embryonic mitochondria (after 24 hr. soaking) actively oxidize this substrate. Also, there is a marked increase with seedling age in the dependence of mitochondrial cytochrome oxidase on exogenous cytochrome *c* for the oxidation of *para*phenylenediamine (Table 1). The injurious effect of the physical environment on the enzyme activities of plant mitochondria, studied by Laties[4], was found to bear no relationship to the inactivation of barley succinoxidase. However, he also observed that mitochondrial enzyme systems suffer damage by processes of an enzymic nature during their isolation. A characteristic feature of mitochondria from barley seedlings which lack the ability to oxidize succinic acid is their relatively high endogenous oxygen uptake ($QO_2(N) = 100$). This value is five to ten times greater than that of mitochondria from mung bean[1] or tomato hypocotyl (Paquin, unpublished work), pea seedling[6], or cauliflower[5]. Similarly, the endogenous oxygen uptake of embryonic barley mitochondria is only one-tenth of the value of those from 4–5-day old seedlings.

Table 1. ENZYMIC ACTIVITIES* OF MITOCHONDRIA FROM BARLEY SEEDLINGS AT DIFFERENT AGES

Enzyme systems	Hours from soaking 24	36	48	60	72	110
Cytochrome oxidase	—	—	282	236	181	48
" with 10^{-4} *M* cytochrome *c*	—	—	347	330	304	253
Succinoxidase	214	172	83	28	0	0
Lecithinase *C*	0	22	—	317	—	648
Lipoxidase	512	—	704	—	—	782

* Average values expressed as $QO_2(N)$ except lecithinase $QCO_2(N)$.

We have shown that the endogenous oxygen uptake of barley mitochondria is catalysed by a lipoxidase which appears to be distributed among particulate and soluble fractions of the cytoplasm. Mitochondria are capable of oxidizing lecithin and linoleic acid, but not oleic acid. The oxidation of these substrates, like the endogenous oxidation, is activated by cupric and ferric ions and is inhibited by diethyldithiocarbamate, hydroquinone and manganous ions, thus characterizing both the endogenous and the substrate-supported reactions as lipoxidase-catalysed oxidations. However, the loss of succinoxidase activity from older seedlings cannot be due to this enzyme, since it occurs in considerable concentration in embryonic tissue from which 'active' mitochondria may be isolated (Table 1).

We have also identified a lecithinase *C* in older seedlings using the method of Zamecnik, Brewster and Lipmann[7]. This enzyme is absent from the embryo but appears early in the growth of the seedling and rapidly increases in activity. Quastel and Braganca[8], and also Nygaard and Sumner[9], have demonstrated the inactivation of succinoxidase in animal mitochondria by lecithinase *A* prepared from snake venom. We believe that by a similar mechanism lecithinase *C* in barley inactivates the mitochondrial succinoxidase system during the course of isolation. The inverse relationship between succinoxidase and lecithinase activity in mitochondria from seedlings of different ages is shown in Table 1. Moreover, this table shows that the dependence of cytochrome oxidase upon exogenous cytochrome *c* is also inversely related to lecithinase activity; but it is clear that other parts of the whole system, perhaps succinic dehydrogenase, are more sensitive to the damaging effect of this enzyme.

Lecithinase *C* is inhibited by sodium fluoride, and the inactivation of succinoxidase in 4–5-day old seedling mitochondria can be partially prevented by adding 0·01 *M* sodium fluoride to the isolation medium (0·4 *M* sucrose, 0·02 *M* phosphate, *p*H 6·8). This protection is increased if the seedlings are infiltrated with 0·02 *M* sodium fluoride under vacuum prior to grinding.

Lecithinase *C* attacks phospholipids at the phosphate–glycerol linkage, yielding phosphorylcholine and a diglyceride. Phospholipids occur in high concentration in plant mitochondria[10], and apparently play an important structural part in the enzymic organization of these bodies. It is evident that hydrolysis of these 'cementing substances'[11] would bring about a breakdown in the functional integrity of complex enzyme systems such as succinoxidase. Mitochondria which lack the ability to oxidize succinic acid have a high endogenous oxygen uptake because lecithinase *C* has caused a partial disintegration of the mitochondrial structure, and the unsaturated fatty acid components of phospholipids have been exposed to the oxidizing action of lipoxidase. Conversely, mitochondria which have a fairly high succinoxidase activity show a low endogenous oxygen uptake because the phospholipids remain intimately associated with the architecture of the particles, and are inaccessible to oxidation by lipoxidase.

Reports in the literature[12] indicating the apparent transience of the whole or part of the succinoxidase system of seedlings may require re-interpretation in view of this demonstration of *in vitro* inactivation by a native lecithinase in barley seedlings.

Grateful acknowledgment is made to the National Research Council of Canada, which provided generous financial assistance for this study.

The Rat as a Test Animal in evaluating Artificial Human Milk for Infants

MANY attempts have been made to develop artificial milk formulations to replace breast milk in the feeding of young infants. Tests have been carried out on infants themselves, and there are very few reports of attempts to use animals in such studies[1-3].

We believe that animal experimentation is necessary in studies of artificial human milk, and we have tried to find an indicator which would rapidly show the influence of different formularies on the animal. We observed that feeding with human milk or cow's milk, respectively, causes similar changes in the fæces of rats and the fæces of infants. Using the *p*H of the fæces as an indicator, we then tried to modify cow's milk in such a way that its effect on the rat would be similar to that of human milk.

The technique used in our experiments was very simple. Rats previously kept on an ordinary laboratory diet were caged individually and fed the milk or milk mixtures to be studied *ad libitum*. No extra water was given, and since the experimental period was always very short (1–2 weeks) no minerals or vitamins were added to the milks. The fæces were collected during a few hours each day, suspended in distilled water and the *p*H of the suspension determined electrometrically.

In the first experiments, three-weeks old weanling rats were used. In accordance with Scott and Norris[1], it was found that human milk was unsuitable for these young rats, whereas the cow's milk permitted some gain in weight (Table 1). In later experiments, older rats (9–22 weeks) were used. Although neither cow's milk nor human milk produced growth in these rats, the animals maintained their weight, and it was evident that the results obtained during the short experimental periods were not due to inanition.

Table 1. EFFECTS OF COW'S MILK AND HUMAN MILK AS DIET FOR RATS OF DIFFERENT AGES

Age of rats	Diet	Average body-weight (gm.) initially	Average body-weight (gm.) at 2 weeks	Gain in weight in 2 weeks (gm.)	No. of survivors
3 weeks	Cow's milk	34	51	17	5/6
3 weeks	Human milk	32	29	−3	4/6
9 weeks	Cow's milk	145	162	17	7/7
9 weeks	Human milk	143	148	5	7/7
22 weeks	Cow's milk	214	220	6	5/5
22 weeks	Human milk	220	215	−5	5/5

In Fig. 1 are given some typical *p*H curves of the fæces of rats fed either human milk or cow's milk. It can be seen that there is a distinct difference between the rats on these two diets. Feeding with human milk has given *p*H values between 5 and 6 whereas cow's milk, on the other hand, has given *p*H values above 7. This difference was usually apparent as early as two days after the beginning of the experiment.

The purpose of the further experiments was to find out how cow's milk must be modified to get the *p*H of fæces down to the human-milk level. A great number of cow's milk modifications were prepared including changes in the quality and quantity of protein, fats, carbohydrates, minerals and vitamins. In most of these cases the *p*H of the fæces did not change in the desired way. However, decreasing the calcium content of the milk and a simultaneous addition of lactose led to positive results. In all experiments with decreased calcium and added lactose the *p*H of the rat fæces was distinctly acid, the acidity curve closely resembling that obtained with human milk.

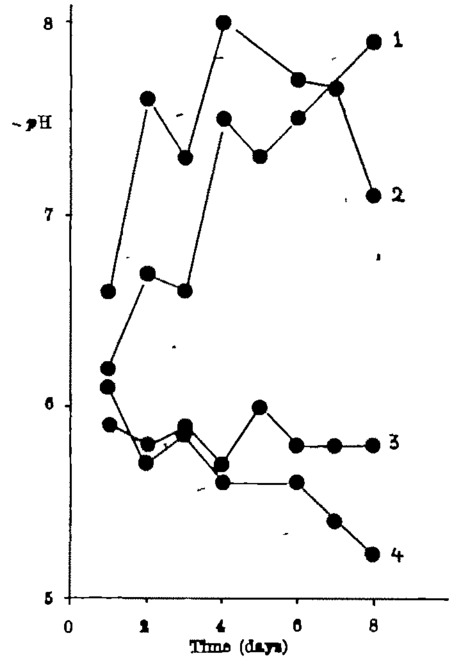

Fig. 1. *p*H of the fæces of rats fed either cow's milk or human milk (averages of 5–7 rats): (1) cow's milk, 9 weeks old rats; (2) cow's milk, 22 weeks old rats; (3) human milk, 9 weeks old rats; (4) human milk, 22 weeks old rats

The calcium content of the milk was lowered by treatment with cation exchangers ('Zeokarb 215' proved satisfactory, removing about 30 per cent of the calcium), by precipitation with sodium sulphate, sodium oxalate or sodium carbonate (cf. ref. 4), or by adding sodium hexametaphosphate ('Calgon') to the milk. The last-mentioned substance, which is known to form soluble complex ions with bivalent ions such as calcium and which is generally used for softening water, has earlier been used by Schwartz *et al.*[5] for the preparation of 'soft curd' milk. Of the different substances tried it was found to be the most suitable for reducing the content of the ionizable calcium. Lactose was added to the milk at the level of 5–10 per cent. Other carbohydrates, for example, dextrin, maltose and sucrose, did not lower the *p*H of the fæces when added to the milk in the same quantities.

The effect of the hexametaphosphate–lactose–milk on the *p*H of the fæces is probably due both to changes in the curdling properties of casein in the stomach and its absorption in the intestines, and to alterations in the composition of the intestinal flora. Further investigations into these questions and into the applicability of such milk formulations as food for young infants are in progress.

Size of Trichostrongyle Infective Larvæ in 'Monobacterial' Culture

In 1911, Looss[1] noticed first- and second-stage larvæ of *Ancylostoma duodenale* ingesting the bacteria 'contaminating' his cultures. He dismissed bacteria as a regular food source, however, because such larvæ "all show the outward signs of insufficient nutrition". Later, it was established by McCoy[2], and confirmed by Lawrence[3], that living bacteria were normally necessary for the nutrition of hookworm larvæ. Lapage[4] also reared the third stages of a number of strongyloid worms, including *Trichostrongylus retortaeformis*, in broth cultures of coliform bacteria. Although McCoy[5] made measurements of *Ancylostoma caninum* larvæ reared in coliform cultures, none of these workers reported any comparisons made between such measurements and those of larvæ grown in ordinary fæcal culture.

Present attempts to obtain standard larvæ of *Trichostrongylus retortaeformis* by these culture methods reveal a constant reduction in the size of the third stage compared with that achieved in fæces at the same temperature. This is so whether the bacteria are available as growing colonies on agar or in broth, or merely suspended in Ringer's solution. If, however, the micro-organism is added to autoclaved fæces, then a suitable environment seems to be provided, for the larvæ reach their normal 'fæcal' size.

The nematode eggs used in cultures 2–5 were extracted from the fæces of infected rabbits by centrifugal-salt-flotation, and surface-sterilized with White's solution[6]. The micro-organisms used as food were *Bacterium coli* Types I and II and an organism intermediate between *Bact. coli* and *Bact. aerogenes* (classification as in ref. 7).

FIGURES FOR 30° C. CULTURES

Type of culture	No of larvæ measured	No. of cultures	Mean length third stage	%
1. Fæces (normal)	100	3	646 μ	100
2. Fæces (autoclaved with coliform added)	50	2	658 μ	102
3. Monobacterial (agar)	250	10	591 μ	92
4. Monobacterial (broth)	50	2	576 μ	89
5. Monobacterial (Ringer's)	50	1	591 μ	92

A *t* test shows that the difference between grand means of (1 + 2) and (3 + 4 + 5) is significant at the 0·1 per cent level of probability.

The techniques to which the eggs and larvæ were subjected have been tested to discover whether they affected the size of the latter in an artificial manner. The results of cultures of type 2 show that centrifugal-salt-flotation of the eggs and treatment with White's solution have no depressing effect on larval size. These same cultures show, in addition, that the strain of micro-organism was not at fault, since it was also used in some of the agar, broth and Ringer's solution cultures. Comparison of larvæ grown in monobacterial flasks closed either with cotton plugs or rubber bungs has shown that limitation of oxygen to this extent has no adverse effect on size. The fact that a rubber bung seal encloses sufficient oxygen for complete development is also brought out by the results for culture 2 (see table), in which such a method of closure was adopted. The possible influence of osmotic phenomena on the size of larvæ extracted from fæces by Baermann technique was examined by the measurement of 'monobacterial' larvæ before and after approximately twelve hours subjection to this treatment. No significant increase in size was noted.

Whether the depression in size is due, as Looss supposed, to nutritional deficiencies in bacteria alone is still not established; but the elimination of many procedural factors makes the existence of a non-living, thermostable, fæcal contribution to larval nutrition a possibility.

Cobalamin Requirement in Chrysophyceae

One of the active principles in aqueous extracts of liver essential for growth of *Ochromonas malhamensis*[1] was identified as cobalamin (vitamin B_{12})[2]. Since this requirement was also found in one or two other chrysomonads, it was suggested that all members of the class might need cobalamin[3]. Some evidence lending further support to this tentative suggestion has recently been obtained from three chrysomonads isolated from brackish supra-littoral pools at Millport: *Monochrysis lutheri* Droop (Strain 60), *Prymnesium parvum* Carter (Strain 65) and *Syracosphaera elongata* nom. prov. (Strain 62).

The three strains, which were grown in bacteria-free culture, required for growth soil or, preferably, liver extract and natural sea water. Both the soil and liver extracts could be replaced completely by cobalamin plus thiamin, the latter apparently having the function of a stimulating substance rather than one for which there was an absolute requirement.

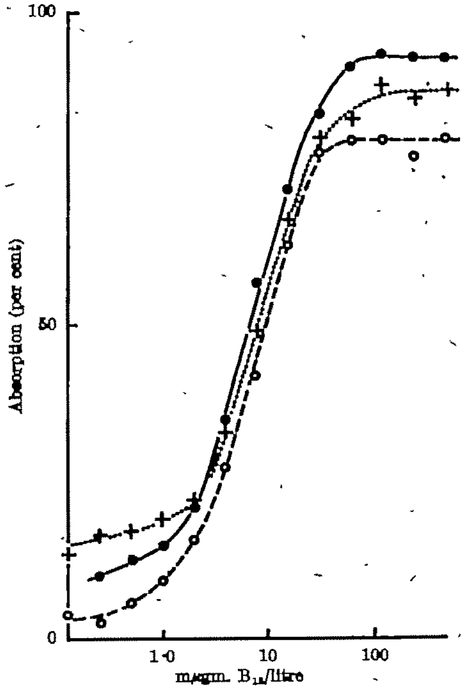

Fig. 1. Response of chrysomonads to doses of cobalamin (Oxo Ltd.). Final yields of cultures measured optically. Continuous curve, *Prymnesium*; dotted curve, *Monochrysis*; dashed curve, *Syracosphaera*

The natural sea water was replaced by an empirical synthetic metal-buffered medium of composition rather similar to Provasoli and Pintner's[3] for *Gyrodinium*, but with guanine and glycine as principal organic constituents. This medium is not ideal and it requires considerable simplification; but it has supported growth of the three strains through nine transfers without undue diminution in yield.

The requirement for cobalamin proved to be absolute and quantitative (Fig. 1); and, so far as experience goes, it was not influenced by the composition of the medium, or eliminated by methionine, some nucleotides and bases. The full pattern of specificity has, however, not yet been ascertained. Maximum growth of all three strains was given by 30–100 mμgm. cobalamin/lit., compared with 200 mμgm. for a marine *Stichococcus*[4], and 100–200 mμgm. for *Euglena*[5]. In the case of *Monochrysis*, maximum yield in culture is about 16,000 cells/c.mm., a figure comparable with that of *Monochrysis* blooms in rock pools but far above any recorded for μ-flagellates in the sea[6]. Concentration of essential nutrients in the pools is probably responsible for the blooms in them; certainly cobalamin must attain a concentration of at least 30 mμgm./lit. On the other hand, it does not appear that this vitamin is a limiting factor in the sea at all times of the year. Preliminary assays with *Syracosphaera* suggest the appreciable figure of 5–10 mμgm./lit. for coastal waters during February and March of this year; Lewin[4] suggests 10 mμgm./lit. If these estimates are even approximately of the correct order, it can be inferred that cobalamin is not a limiting factor in the early spring.

Gene Frequencies in Strains of *Trifolium repens* L.

The frequencies of glucoside lotaustralin and enzyme linamarase genes were investigated in lowland[1] and altitudinal[2] populations of *Trifolium repens*. The results obtained disclosed a continuous diminution in the occurrence of the dominant alleles from the Mediterranean region to north-eastern Europe[1], and from the lowland to the higher altitudes[2] within a range of 100–0 per cent. A significant correlation was found between the dominant allele frequencies and January mean temperature. Further study was concerned with the determination of gene frequencies in strains of *T. repens*. The picrate-paper test used was that described by Corkill[3], modified for determining small amounts of enzyme. The results obtained were used for calculating the occurrence of genes in the samples (Table 1).

The dominant glucoside allele (*Ac*) shows a decrease from 100 to 0 per cent, and the dominant enzyme allele (*Li*) from 86·3 to 10·5 per cent. Striking similarity became evident in the gene frequencies of wild and cultivated strains of *T. repens* derived from the same geographical region. The British and New Zealand strains possess high frequencies of the dominant alleles. In contrast, the Swedish, Danish and north Italian strains show comparatively low frequencies of the dominant alleles, with the exception of the Weibull's Robusta and Nora for enzyme gene.

Table 1. Frequencies of the Dominant Glucoside Lotaustralin and Enzyme Linamarase Alleles in Strains of *T. repens* (per cent)

Strains	Origin	No. of plants	Glucoside allele *Ac*	Enzyme allele *Li*
S.100 Nomark	British	321	100·0	86·3 ± 1·92
Kersey	British	151	88·5 ± 2·60	60·1 ± 3·98
S 100	British	332	80·2 ± 2·19	79·5 ± 2·22
N.Z. certified 'Mother' seed	New Zealand	178	60·5 ± 3·72	66·0 ± 3·60
S.184	British	304	57·5 ± 2·84	59·4 ± 2·82
N.Z. certified 'permanent pasture' seed	New Zealand	104	44·5 ± 4·87	50·0 ± 4·90
Morse	Danish	116	17·1 ± 3·51	10·6 ± 2·87
Weibull's Robusta	Swedish	183	8·6 ± 2·07	72·3 ± 3·31
Ladino	Italian	129	5·2 ± 1·95	25·8 ± 3·85
Weibull's Nora	Swedish	165	4·7 ± 1·65	74·2 ± 3·41
English Dutch	Dutch	126	2·8 ± 1·47	10·5 ± 2·73
Weibull's Tetraploid	Swedish	149	0·0	15·2 ± 2·92

The picrate-paper test also gives an indication of the relative chemical output of the gene. According to the amount of gene product, six colour reaction classes were distinguished. There was a positive correlation ($r = 0{\cdot}8971$, $P < 0{\cdot}001$) between the gene frequencies and the chemical output of the gene (Fig. 1).

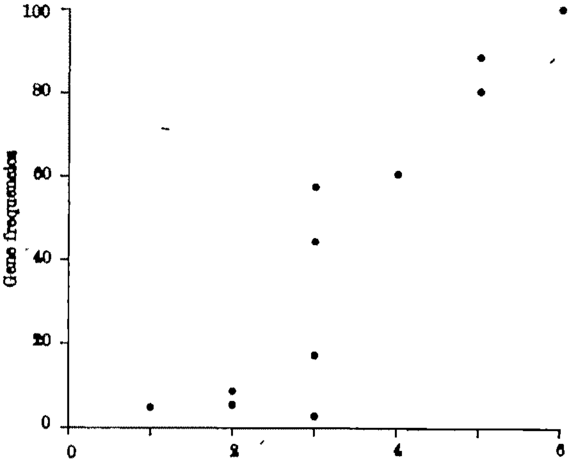

Fig. 1. Relation between the frequencies of the glucoside lotaustralin gene and the reaction intensity plotted as modal reaction classes

I consider that the variation between the gene frequencies in the samples of *T. repens* derived from different geographical regions is governed by natural selection.

I am indebted to Prof. T. J. Jenkin, former director of the Welsh Plant Breeding Station, for facilities for carrying out this investigation, and to Mr. Watkin Williams, former head of the Clover Breeding Section of the Station, for suggesting the experiment, and to Mr. R. C. O. Davies for his help.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Sunday, September 12—Friday, September 17

Society for Experimental Biology (in the Lecture Theatre, Department of Physics, The University, Leeds)—Symposium on "Fibrous Proteins and their Biological Significance".

Monday, September 13—Friday, September 17

Association of Applied Biologists (at Imperial College, South Kensington, London, S.W.7)—Jubilee Conference.

Monday, September 13—Saturday, September 18

International Union of Nutritional Sciences (at Amsterdam)—Third International Congress of Nutrition.

Wednesday, September 15—Friday, September 17

Faraday Society (in the Department of Chemistry, The University, Sheffield)—General Discussion on "Coagulation and Flocculation".

Friday, September 17

British Society of Rheology (in the Main Chemistry Lecture Theatre, Imperial College, Imperial Institute Road, London, S.W.7), at 11.15 a.m.—Conference on "Viscoelasticity in Solids, Emulsions and Solutions".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Museum Assistant (with a degree, including geology to at least pass standard, and an interest in palaeontology) in the Geology Department—The Secretary, University College London, Gower Street, London, W.C.1 (September 18).

Lecturer or Assistant Lecturer in Psychology—The Secretary, London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2 (September 20).

Lecturer or Assistant Lecturer in the Department of Pure Mathematics—The Registrar, University College of Wales, Aberystwyth (September 20).

Scientific Officer (with an honours degree in bacteriology, or an honours degree in science with a diploma in bacteriology, and preferably with a good knowledge of chemistry) in the Bacteriology Department—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (September 20).

Lecturer (with good academic qualifications and practical experience in the electrical engineering industry) in Electrical Engineering—The Registrar, The University, Leeds (September 21).

Physicist (with a first- or second-class honours degree in physics, and considerable experience of instrumentation research and development), in the Rocket Propulsion Department, Ministry of Supply, Westcott, Bucks, to lead a small section on rocket instrumentation research—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.235/54A (September 29).

Bacteriologist (graduate, with postgraduate training or experience in bacteriology), at the Wallaceville Animal Research Station, New Zealand Department of Agriculture, for research concerning the control of bacteriological diseases of domesticated animals—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting 3/4/37 (September 30).

Senior Lecturer (with a degree in statistics or in mathematics with research experience in statistics) in Mathematical Statistics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (September 30).

Experimental Officer or Assistant Experimental Officer, in the Pomology Section, to assist with laboratory and field investigations on effects of orchard soil management practices, on the tree and the soil—The Secretary, East Malling Research Station, near Maidstone, Kent (October 1).

Senior Lecturer or Lecturer in Mathematics at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 15).

Chair of Physics; Chair of Chemistry; Chair of Botany; Chair of Zoology at University College, Salisbury, Southern Rhodesia—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 18).

Chair of Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (October 25).

Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar, The University, Manchester 13 (October 30).

Lecturer (with an honours degree in chemical engineering or equivalent with postgraduate or industrial experience in chemical engineering) in Chemical Engineering, and a Lecturer (with an honours degree in petroleum, chemical or mechanical engineering or geology, with postgraduate or industrial experience) in Petroleum Production Engineering—The Registrar, The University, Edgbaston, Birmingham 15 (November 1).

Senior Lecturer (specializing either in soil science or in agricultural organic chemistry) in Agricultural Chemistry, at Makerere College, University College of East Africa—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (November 30).

Head (with research and teaching experience) of the Physics Department—The Northern Polytechnic, Holloway, London, N.7.

Senior Technical Officer (with a degree in agriculture or botany or equivalent qualifications, and with practical experience in seed production), in the Herbage Section of the Seed Production Branch—The Secretary, National Institute for Agricultural Botany, Huntingdon Road, Cambridge.

ADULT EDUCATION IN GREAT BRITAIN

WRITING on "Democracy and its Discontents" in the June issue of *Encounter*, Mr. M. Beloff argues that the outstanding event in the political history of the past hundred and fifty years in Britain is the development of the Civil Service and of an educational system which has taken enough account of the claims of talent to enable it to create a race of administrators capable of maintaining the consistency of government in spite of the advance towards democracy. Implicit, if not explicit, in this argument is the plain truth, which no party politician dare admit, that wise government is impossible if the discretion of Ministers placed in office by a political party majority is fettered by having continually to consider the effect on voters of taking the measures which are clearly indicated by facts known to them in office but which are unknown, and cannot be made known, to the electorate, even if the electorate were able to appreciate their significance. Efficient and skilful government is, in fact, impossible if many decisions to-day are not removed from the range of popular choice.

Mr. Beloff does not, however, regard the excessive power of the party system or decrease in the prestige of Parliament as the real menace to the stability of British parliamentary institutions to-day. Rather it lies in the possibility of a serious attempt to achieve literal educational equality and to kill the élite which has enabled us to afford the luxury of popular government. The claim that British democracy has been so successful largely because it has become undemocratic is not likely to pass unchallenged. It will at least be asked what has been the cost to the quality of public life and to the wisdom of public policy. Nevertheless, whatever reservations are made as to the full validity of Mr. Beloff's argument, it emphasizes the importance of education for leadership and of maintaining the highest standards of training in the schools and universities from which our future ministers, administrators and experts are drawn. In the context of such episodes as Crichel Down, the words of the University Grants Committee in 1936 regarding the responsibility of the universities are indeed pregnant: a university should stimulate and train its students "at least to think, and to think strenuously about the great issues of right and wrong, of liberty and government, on which both for the individual and for the community, a balanced judgment is essential to a rational life".

While Mr. Beloff, at least by implication, thus emphasizes the importance of education for leadership and the danger inherent in any educational policy which by levelling down hinders the emergence of such an élite, Sir Ivor Jennings's recent exposition of the working and institutions of British democracy, "The Queen's Government", points to the importance of education at the other end. He finds an explanation of the stability of British institutions rather in the fact that the coming of universal suffrage has placed the balance of political power in the community into the hands of the lower ranges of the middle class, mainly salaried employees and small proprietors, whose votes determine which political party shall win the relatively few marginal seats. The interest of these voters is on the whole against violent change, and since political parties must appeal to these voters, violent conflicts of principle are abated and a high degree of uniformity imposed on party programmes.

Whether or not Sir Ivor Jennings's theory be correct—and his view does not necessarily exclude Mr. Beloff's—it indicates the importance of adult education if the issues of the day are to be resolved more impartially and factually and less according to party political doctrines. The stress lies on instruction of the electorate rather than on parliamentary discussion if the findings of the expert are to be used fully in shaping policy. Much more practical thinking about the functioning of Parliament and the relations between Parliament and Minister and administrator and expert is clearly required than Mr. Herbert Morrison foreshadowed in his recent book, "Government and Parliament: Survey from the Inside". The Crichel Down debate in the House of Commons on July 20 at least indicated an awareness of such issues and some readiness to examine them.

While the time is opportune for a re-examination of the working of our Parliamentary institutions and of the philosophy upon which they are based, that examination should be conducted with reference not merely to the structure of government itself and to the men and women responsible for the task of government, whether Ministers, Members of Parliament, or Civil Servants, but still more to the capacity and limitations of the public who placed them in power. In essence it is a re-examination of the problem of power and influence within the framework of a democratic society under the impact of technological change, and the critical factor is likely to be at least as much the receptivity and adaptability of the average citizen as the wisdom, initiative and ability of those responsible for the task of government. If the Technical Assistance programme or the Colombo Plan have done nothing else, they have demonstrated how sharply technical assistance and economic advance in the relatively undeveloped areas of the world are limited by the general standard of education and understanding of the peoples of those areas, as well as their capacity for self-discipline and co-operation.

Those factors set the limits of government action no less sharply among the more advanced nations. If Britain, for example, is to take full advantage of the opportunities of economic development and of raising the standard of living which technological development has made possible, much will depend on the ability of statesmen to secure public understanding and co-operation in the changes, the displacements and sacrifices that may be involved. There is no room for the demagogue in such developments, or in such institutions if the Social Welfare State is to endure. An educated electorate is as essential a condition as wise and competent leadership.

Recognition of this and of the dangers inherent in the present position lies behind much of the concern with which the Government's proposals in regard to television and broadcasting are regarded by responsible leaders of all political parties and walks of life. It is also a reason why educational policy is so important an issue. Even the persistent shortage of science teachers is a factor to be considered here. The direct effect of that shortage is to handicap plans for the expansion of technological education, for example, and to make it more difficult for the nation to obtain the increased numbers of well-trained scientists and technologists who are required in industry, in government service and in the universities and technical colleges. It also affects, however, the recruitment of teaching staff for such institutions, and the number of those coming forward from the schools to enter on careers in science and technology.

But a shortage of science teachers in the schools does not merely affect the supply of those who are willing and ready to undertake studies in science and technology at the university—or technical college—level. It limits the number of those whose general education enables them to leave school with some understanding of what science is—and is not—and of the bearing of applied science on everyday life. This effect, moreover, is likely to be accentuated by the general shortage of teachers required to meet the substantial rise in the school population between now and 1960 by up to some 20 per cent on the 1950 figure. From 1960 onwards there are likely to be ten per cent more children in the schools than in 1950, and unless the present annual increase in the number of teachers is fully maintained, the proportion of children receiving education even of the standard provided in 1950 is likely to fall. Prospects of a ten per cent increase in the number of those entering on a scientific or technological career merely through the overall increase in the school population are slender, even if the shortage of science teachers is removed.

From this point of view a determined effort to reduce the size of classes at least below the regulation forty might be well worth the price demanded. For the next generation, however, the standard of public understanding will depend in large measure on adult education. Indeed, debates on education in the House of Commons suggest that the measures required to avert a fall in the standards of primary and secondary education by eliminating the over-size classes and to secure the wisest use of our limited reserves of trained man-power must wait on the support which an informed public opinion could give.

Since the county colleges for further education now appear to be a remote possibility of the future, the main responsibility for adult education must lie with existing agencies. Admittedly, as Mr. Ernest Green points out in his book "Adult Education—Why this Apathy?"*, adult education must begin in the schools, and the desire for liberal education, as distinct from mere vocational training, is either stimulated or stifled at the time of leaving school. This situation may well have to be accepted for the next ten or fifteen years. By that time we may have, as he suggests, enough teachers, better trained and with wider experience of life, adequate buildings and equipment and a curriculum which is less concerned with the job a boy or girl is to enter and more concerned with their minds, character and personality; in that event, the schools will indeed be producing citizens in the schools instead of clerks, shop assistants, apprentices, etc.

---

* Adult Education: Why This Apathy? By Dr. Ernest Green. Pp. 146. (London: George Allen and Unwin, Ltd., 1953.) 15s. net.

In the meantime, we have to face a situation in which the schools are still failing to lay the foundations for good and responsible citizenship and to strengthen the moral and spiritual values on which such citizenship is based and the preservation of all that is best in a cultured, democratic way of life. In this context the concern with which the passing of television under influences that are not primarily swayed by the idea of public service is regarded can be understood. As the Government's White Paper admits, "television has great and increasing power in influencing men's minds", and the Beveridge Report had earlier recognized that broadcasting could increase the danger of the passive acceptance by the masses of orders given to them and of things said to them. Such passivity is a serious danger to democracy and free institutions to-day, and one which television, even more than sound broadcasting, encourages.

Moreover, this concern over power and responsibility in television takes place at a time when, as various re-examinations of adult education, prompted in part by the celebration of the jubilee of the Workers' Educational Association, have shown, there appears to be a decline in both the efficiency of existing means of adult education and in the interest taken in them. Dr. Green, for example, points out that approximately one in four of the school leavers covered by his inquiry make no apparent effort to follow up their school experience, even in the direction of vocational training; and of those who do, nine out of ten appear to be uninterested in the arts or the humanities. Well may he urge that we should regard training for a job or profession as only one incident in the educational process, and that the curriculum should be one in which ideas are discussed and the student taught how to discover the facts for himself.

While Dr. Green rightly argues that we must relate all forms of education to life in society, when it comes to ways and means he focuses his attention on what he terms the educationally under-privileged, and the view he takes of the functions of the Workers' Educational Association is correspondingly narrow. He would limit its activities to meeting the needs of the manual worker. In this he takes an even more restricted view than was taken by the working party under Mr. A. Creech Jones's chairmanship which recently reported on trade union education to the Workers' Educational Association. That report called for a more specific and concentrated effort by the Association to meet the needs of the trade union movement; but it showed also a real awareness of the implications of the situation to-day, and did not suggest a policy limited exclusively to meeting even the widest educational needs of that movement.

The two reports reach similar conclusions regarding the measures which might be adopted to meet the limited demand, particularly by way of supplementing the tutors which the Workers' Educational Association draws from the universities. Useful as may be the experiments suggested, particularly in the effect on leadership in the trade unions, neither Dr. Green nor the working party pays attention to the wider aspect of the extra-mural activities of the universities. Only to a limited extent do they share the conception of adult education which Prof. R. D. Waller displays in his appreciation of H. Pilkington Turner: "Adult education", wrote Prof. Waller, "is what happens when knowledge is transmitted from mind to mind in such a way as to kindle a glow of love and hope and faith in life, and to confirm both those who give and those who receive in their sense of the dignity of human destiny and of their own responsibilities in the face of it".

Adult education in that sense is exactly what is needed to vitalize a democratic society to-day and to enable it to preserve its traditions and its free institutions. Broadcasting and television could help to encourage the receptivity on which such education proceeds; but they could equally, if misdirected, prove formidable obstacles to this enlargement by inspiration. This is not to deny that broadcasting has played an important part in raising the standard of public taste and understanding over the past twenty or thirty years; but that influence is due in large measure to the conception of public service which has dominated broadcasting policy. Only time can show whether the safeguards written into the Television Act will be adequate to ensure that the influence of television on standards is beneficial and that its educational possibilities are fully utilized.

Even if it is only to encourage the background of interest against which adult education proceeds most effectively, the importance of broadcasting and television is not to be under-rated. It is difficult to accept Prof. Robert Peers's statement that the most serious obstacle to the rapid development of science courses in adult education is the absence of any general interest in science. It may be true that the demand for science courses in extra-mural education is not advancing as briskly as might have been expected; but there is abundant evidence of a widespread interest in science which finds expression, for example, in the activities of amateur scientists in many ways. Such activities may not lead to any understanding of science as a whole and its implications; but they testify to an interest which in adult education could and should lead to such understanding, if teachers or tutors are available.

The supply of teachers is most probably the critical factor, and perhaps all the more if in future we are to look to the day-release class rather than to the traditional evening class as a vehicle of adult education. Scientists are showing themselves increasingly aware of the importance of explaining themselves. Though there are defects in scientific education in Britain to be overcome—and especially a tendency to segregate scientists—the danger is now more generally appreciated, and it is noteworthy that all proposals for the expansion of technological education seek to minimize that danger.

Scientists are already co-operating in extra-mural activities, and for all who possess some capacity for interpretation and exposition to participate, either formally in extra-mural activities, through their professional associations or in private in such ways as are open to them, this task of assisting in the public understanding of science and its implications, is one of the most important ways in which they can to-day discharge their obligations as citizens. The extent to which they respond to this need and take part in the critical discussion of proposals designed to alleviate the immediate shortage of science teachers, and assist in the most effective use of the resources at our disposal for teaching science and technology generally, will largely determine the ability of democratic institutions to adapt themselves to the needs of to-day, and to throw up leaders capable of formulating the policy required to preserve those institutions and their traditions. Whatever changes may be necessary in the nature of adult education, any limitation or segregation of students to particular social classes or industries would be deplorable.

Objective teaching cannot take place in the context of class prejudice, and the bringing together of a wide range of social strata, of men and women of varied experience and outlook, is a prerequisite if adult education is to make its full contribution to that balanced outlook and public understanding on which the continued functioning of free and democratic institutions so largely depends. It may at least be hoped that when the Minister of Education receives the report of Dr. Eric Ashby's committee on the finance and administration of adult education, she will be able to announce a policy that will do more than remove the uncertainties which, as the last report of the Universities' Council for Adult Education shows, have hindered work in this field for the past eighteen months or more. Not only is a policy required which will permit development to be planned with confidence while giving the necessary flexibility for vitality and wealth of experiment; it should equally encourage that type of adult education to which the Prime Minister referred in his message last year to the General Council of the Trades Union Congress: "The mental and moral outlook of free men studying the past with free minds in order to discern the future demands the highest measures which our hard-pressed finances can sustain". If it is also true that, as Sir Winston continued, the appetite of adults to be shown the foundations and processes of thought will never be denied by a British administration cherishing the continuity of our island life, it is no less true that the continuity of effective administration and of free institutions may well depend on the extent to which public understanding is fostered in exactly that way.

BIOCHEMISTRY OF GENETICS

The Biochemistry of Genetics
By Prof. J. B. S. Haldane. Pp. 144. (London: George Allen and Unwin, Ltd., 1954.) 15s. net.

THIS book, by Prof. J. B. S. Haldane, is, as one has come to expect, a remarkable, a stimulating, and yet a motley work. The brief volume is an outgrowth of a series of lectures delivered to the Department of Biochemistry, University College, London, in 1950 and 1952, and is thus directed primarily towards biochemists. The contents, however, may well prove even more stimulating to geneticists.

Haldane discusses primarily the action of genetic material, described in biochemical terms as deduced from studies on viruses, bacteria, fungi, higher plants and animals. He describes in brief terms the genetic control of biochemical reactions in bacteria and fungi, of pigment formation in higher plants and animals, of antigen formation, and the genetics and biochemistry of a variety of inborn metabolic errors in man. Thus the book is remarkable for the great diversity of material considered from a common point of view, and so bears testimony to the extraordinary wide reading and interests of the author. It is, in fact, this breadth of material as well as the point of view of the author which makes the book stimulating reading.

The brevity of the treatment of such a diverse field leads of necessity to a somewhat superficial consideration, as well as to a great deal of unevenness in the material covered. Furthermore, in considering fields in which he himself has not worked, Haldane's choice of material is rather selective. The book also contains numerous errors of fact. Thus, this work should not be used as a reliable source of information, but is rather a delightful essay on the genetics of biochemistry.

One cannot read this volume without deriving pleasure from certain sallies of the author, and taking exception to others. Thus Haldane's observation of the lack of appreciation by the "American School" of the origin of the postulate that genes make enzymes is a happy one and perhaps justified. On the other hand, when considering the Neurospora work of the "American School" he comments: "It is moreover possible that more is known than has been published. Some of the workers concerned are now paid by the Atomic Energy Commission and such an affiliation at best imposes a delay on publication, at worst holds it up indefinitely". It may well be true that more is known than has been published; but if so, as far as this reviewer knows, it is for human rather than political reasons. While it is true that a great deal of research on microbial genetics is supported by the United States Atomic Energy Commission, this support has facilitated research and has neither suppressed nor delayed publication in this unrestricted field. Haldane's book also has many political quips concerned with the Lysenko controversy. These lose a great deal, however, as Haldane poses the problem primarily on the basis of whether Lysenko is right or wrong, where it would appear to many that the controversy is on an entirely different level, namely, does Lysenko make use of truly objective scientific methods? This obscurantism again does not seriously detract from the book as a whole, since it consists primarily of asides and thus does not enter into the mainstream of the problems under consideration.

In reading the book as an essay, one derives great pleasure and stimulation, a great deal of which comes from the breadth of knowledge and interests of the author. The conclusions concerning the nature of gene action are refreshingly different. Haldane feels that biochemical genetics is approaching a critical epoch, a time one may well be able to specify what a given unit of genetic material is doing. With this most geneticists will agree. He feels, however, that this knowledge will stem from a study of 'vitaminless' mutants rather than 'amino acidless' mutants, as he feels the action of gene-controlling vitamin synthesis may well be direct, while the genetic control of amino-acid synthesis must be indirect. The evidence for such a difference in the action of genetic material is scant indeed, and, in the opinion of this reviewer, based on studies not referred to by Haldane, this difference is improbable. The discussion of problems of this nature makes, however, for pleasant speculation. Lastly, Haldane concludes that genes need not act by a direct replicating process, but rather that genetic material in its action and replication passes through a cycle involving intermediate states. Considerations of this sort have been given scant attention in recent years, and it is with pleasure that one reads and ponders these ideas, since the straws in the wind suggest that they will be the problems of the future. DAVID M. BONNER

STRESS WAVES IN SOLIDS

Stress Waves in Solids

By H. Kolsky. (Monographs on the Physics and Chemistry of Materials.) Pp. x+212+3 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1953.) 25s. net.

STRESS propagation in solids has recently become the object of a remarkable revival of interest. This is partly due to the recent development of electronic apparatus capable of generating and detecting stress pulses; for, without this, experimental work was a matter of considerable difficulty. Further, the study of stress pulses of large amplitude is obviously of military importance, and the Second World War not only focused attention upon elastic waves but also led to the initiation of plastic wave theory. However, those who are interested in stress waves have been handicapped by the lack of a reference book on the subject and by the state of the literature, which has become scattered in journals of engineering, physics, seismology, acoustics and mathematics. In writing this monograph, the author has materially improved the situation.

The book is divided into two parts and, of these, the first is concerned with elastic waves. The introduction to this subject is very clear and includes a brief treatment of æolotropic media. The theory of the extended isotropic solid is dealt with in detail, and some of the effects which are associated with boundaries are discussed; these include the two-dimensional problems of Rayleigh waves, reflexion and refraction. A chapter on propagation in bounded solids includes an outline of the various engineering theories of thin rods together with the 'exact' Pochhammer treatment of cylinders and a discussion of the ways in which the former approximate to the latter. The rest of this part of the book deals with experimental investigations, and mention is made of the well-known pressure-bar experiments of B. Hopkinson and of R. M. Davies. Some recent work on ultrasonics is summarized very briefly.

In the second part of his book, the author deals with stress waves in imperfectly elastic media; this is particularly welcome. It starts with a treatment of internal friction and stress propagation in visco-elastic solids. A chapter is devoted to the experimental determination of dynamic elastic properties and includes a discussion of results. A very interesting treatment is given of plastic and shock waves in solids, which includes the theories of G. I. Taylor, Th. von Kármán and K. A. Rakhmatulin for the infinite wire. In the last chapter, the author deals with the important subject of fractures produced by stress waves; he mentions the work of J. Hopkinson and of B. Hopkinson and describes the very illuminating experiments which he and his associates have made and which will surely become very well known.

The list of references indicates that the work is intended chiefly for the physicist; while it is excellent for this purpose, the engineer will find this list inadequate in some respects. The book is written lucidly and the mathematics is simple. Thus, the elasticity equations are presented in component form in the manner of Timoshenko, and the use of vectors is reserved as the subject of an appendix. There can be no doubt that this book will be widely read. It is excellently written and is a valuable contribution.

R. E. D. BISHOP

MKS UNITS

The M.K.S. System of Units

A Guide for Electrical Engineers. By T. McGreevy. Pp. xii+283. (London: Sir Isaac Pitman and Sons, Ltd., 1953.) 21s. net.

IN Britain, general interest in the MKS system of electrical units really began some four years ago with the publication by the Institution of Electrical Engineers of a symposium of papers on the subject. Since that time, the rationalized MKS system has gained considerable popularity with teachers, quite apart from its adoption in technical practice, and several short explanations of it have been published. Mr. T. McGreevy's book is considerably fuller than any of these, and is written both for the engineer who is concerned with using the system, and the teacher of electrical engineering for whom it offers new approaches to the subject. It will interest also teachers of physics, for the author discusses the fundamental principles of measurement in some detail.

The œrsted, gauss and maxwell always seemed to have a firm co-opted status as practical units, and it may be harder for the engineer to learn to think habitually in amperes per metre and volt-seconds than it is simply to accept the change of units. Here the book should be most helpful. The author derives many of the chief results in motor, generator and transformer theory from first principles, gives some worked examples on the properties of magnetic materials, and has tabulated formulæ and conversion factors for reference.

The earlier chapters are directed chiefly to teachers in technical colleges. A scheme for introductory classes at two different standards is outlined, in simple terms for part-time students and in a more analytical form for full-time students. With the ampere established as the fourth fundamental unit, the definitions of H as the line integral of I and of B in terms of a flux-cutting e.m.f. are logical first steps in electromagnetism. The ballistic galvanometer is used in the earliest stages, and no objection to using an instrument before its full theory is taught can fairly be made by teachers whose own study of electricity was probably initiated with the leaf electroscope. The treatment at both levels is convincing (though at one stage an imaginary experiment is invoked), and should be readily understood by students, which is its justification. In developing an introductory treatment, the teacher is rather in the same difficulty as the centipede; concern for logical sequence will not necessarily make things run more smoothly. The basis for accepting the Biot–Savart law and the first circuital theorem is the experimental work of Ampère; but a purely deductive approach on these lines would be too severe. Again, a rigid deductive presentation founded on Coulomb's law is within the grasp of accomplished mathematicians; but no beginner could ever understand it. Mr. McGreevy asks the student to accept the first circuital theorem and the concept of magnetomotive force with the help of rough quantitative experiments, and after this the path is clear and easy to follow.

The book is to be recommended, and should meet a need which has been felt for some time. It should also stimulate much thought and discussion about elementary teaching methods. G. R. Noakes

PROF. MEGHNAD SAHA: SIXTIETH BIRTHDAY TRIBUTE

Professor Meghnad Saha

His Life, Work and Philosophy. Edited by S. N. Sen. Pp. viii+176+19 plates. (Calcutta: Meghnad Saha Sixtieth Birthday Committee, Indian Association for the Cultivation of Science, 1954.) 5 rupees; 10*s.*; 1.50 dollars.

THIS account of Prof. Meghnad Saha's scientific and political career has been issued as a tribute to him in celebration of his sixtieth birthday by a committee under the chairmanship of Prof. D. S. Kothari. It emphasizes, rightly, Prof. Saha's pioneer work on thermal ionization and selective radiation pressure which established his position in the world of astrophysics more than thirty years ago and led to his election to the Royal Society. But his heart was in physics, and it was only after a considerable output of papers on purely spectroscopic problems and nuclear physics that he returned to the solar corona as a subject of study. Active interest in the propagation of electromagnetic waves in the ionosphere led later, with the development of radio-astronomy, to further work on radio-waves escaping from the sun and stars.

Meanwhile, Prof. Saha had been living a very active and successful life as a professor of physics at Allahabad and Calcutta, building up research schools in ionospheric studies and nuclear physics. He had become an active member and leader in the development of scientific societies and other activities in India. The Indian Science Congress, the United Provinces Academy of Sciences (later the National Academy of Sciences, India), the Indian Association for the Cultivation of Science and the National Institute of Science, all in turn elected him as president. Prof. Saha was also mainly instrumental in the formation in Calcutta of an Institute of Nuclear Physics for training personnel and carrying out fundamental research. He was appointed honorary director of the Institute. He was also a member of the Board, later the Council, of Scientific and Industrial Research. Through many articles, signed and unsigned, in *Science and Culture*, Prof. Saha published his views on science and its social relations.

In 1951 Prof. Saha stood for Parliament as an independent member and was elected by a large majority. In his work as a member of Parliament he has been concerned with education, industrialization, river valley projects and national planning. Throughout his life he has been a fighter for causes which he felt to be right, and it is largely due to his forthright spirit that he has risen from a humble beginning to the position of leadership that he holds to-day in the world of Indian science.

FOSSIL BOTANY

An Introduction to the Study of Fossil Plants

By Prof. John Walton. Second edition. Pp. x+201. (London: Adam and Charles Black, 1953.) 30*s.* net.

THERE have been many notable advances in the field of palæobotany since the first edition of this useful text-book was published in 1940; the problem in preparing the second edition has been to make a limited selection of these for inclusion, and this the author has done chiefly from among the pteridophytes and pteridosperms of the late Palæozoic. For example, as further illustration of significant phases in the evolution of some of the chief groups of vascular plants, substantial information is included about the structure of the Lower Carboniferous horsetail cone *Protocalamostachys*, in particular of its sporangiophore; about the structure of various Carboniferous seeds, especially *Calathospermum* and *Salpingostoma* from the Scottish Calciferous Sandstone Series; and about the demonstration of heterospory in the Carboniferous fern *Stauropteris*. Space has also been found to add a brief discussion of such recent critical studies of more modern seed plants as Simpson's stratigraphical use of Tertiary pollen floras from Mull and Ardnamurchan, and Elias's work on grass fruits in studies of the evolution of the grasslands of North America during the Miocene and Pliocene—the latter of particular palæontological interest in its relationship to the evolution of the horse.

The opportunity has also been taken to revise some of the useful tables of stratigraphic correlations, and of age of geological periods, to bring them into conformity with more modern data; and the final chapter on climate and world floras has been amplified, with a broader discussion of evolutionary aspects and including such a recent theory as Hoyle's astrophysical explanation of the former occurrence of tropical floras at high latitudes.

When so many sections of the book have thus been brought up to date within the limits of the publication, it is indeed to be regretted that space could not have been found to revise the chapters on the Cordaitales, Coniferales and Cycadales; for in these groups some of the most significant of the recent additions to palæobotanical knowledge have been made through the work of Florin, Harris and others. It is to be hoped that in any future edition the account of these groups may be amplified, for the existing text-books on gymnosperms are notoriously out of date in this respect.

MYXOMATOSIS IN BRITAIN

By Dr. C. H. ANDREWES, F.R.S.

National Institute for Medical Research, Mill Hill, London, N.W.7

THE deliberate introduction into Australia of myxomatosis or rabbit-plague has undoubtedly brought immense economic benefit to that country. Rabbits are a pest in Britain also, and myxomatosis has now reached these islands. Are we to expect wholesale destruction of our own wild rabbit population and corresponding economic gain ? The answer to these questions is not easy, for myxomatosis seems to be behaving very differently in South America, which is its native land, in Australia, in France and in Britain.

In South America the virus of myxomatosis infects the native rabbit or tapeti (*Sylvilagus brasiliensis*), causing a non-fatal disease and being carried by mosquitoes (*Aedes* spp.). Its existence became known when, in 1898, it infected Sanarelli's laboratory rabbits in Montevideo and almost wiped them out. Domestic rabbits are derived from wild European rabbits, *Oryctolagus cuniculus*, and, in them, in contrast to the tapetis, myxomatosis is almost uniformly fatal. Accordingly, Aragão[1] suggested that the virus could be used for exterminating wild European rabbits where these were a pest, as they decidedly are, especially in Australia.

Early attempts to follow up this idea in Australia, Britain and Scandinavia attained only limited success: the disease obtained no permanent foothold. In 1950 further attempts were made in Australia to use the infection for destroying wild rabbits. Six of seven liberations apparently came to nought; but the seventh, just when it was thought to have failed likewise, suddenly flared up over unexpectedly wide areas. Probably it was spread by mosquitoes. Since 1950 myxomatosis has spread over much of south-eastern Australia, where it is estimated to have killed four-fifths of the rabbits in 1952–53 and to have increased rural production by £50,000,000.

In 1952 a French doctor introduced the infection into his estate south of Paris. He succeeded in his object of killing off his wild rabbits; but the disease did more: it spread beyond his park and in less than two years it had covered most of France and has now reached the north of Scotland. Why the disease has been spreading so widely when previous attempts to introduce it failed, we do not know. In France, the disease was by no means generally regarded as a blessing. Possibly the economic gains were on balance greater than the losses. But the disease affected not only wild rabbits but also the tame ones in rabbitries, which are of much economic value; and the *petits chasseurs* were very vocal because their week-end sport was spoilt.

Myxomatosis reached Britain about September 1953—how, we do not know. It could have been deliberately introduced by man, carried in infected mosquitoes or in rabbit fleas which had become accidental passengers on birds. The occurrence of the early outbreaks in counties facing the Channel—Kent, Sussex and Essex—suggests a natural method of spread rather than an intentional introduction. In view of the early failures to spread the disease, it seemed likely that the disease might die out during the winter months. On the contrary, it smouldered in its original foci and new centres of infection were reported nearly every week in south-east England.

Late in 1953 an advisory committee was appointed by the Minister of Agriculture and Fisheries and the Secretary of State for Scotland. Its first decision was to approve the attempts made by the Ministry to 'contain' the early outbreaks, to give time for the whole position to be assessed. But the virus was not to be contained; it spread despite man's efforts and with increasing momentum as summer followed spring[2]. There is no doubt that when farmers began to realize that they had much to gain from destruction of rabbits, they obtained infected animals and released them on their own properties. The bigger 'jumps' of infection in the early summer of 1954 can be traced to such introductions.

The official attitude hitherto has been to take no part in, and in fact to deprecate, intentional spreading of the disease. A major reason for this concerns an aspect of the disease not yet discussed: the disease is a very unpleasant one. Infected rabbits are of a revolting aspect; their eyelids are so swollen that their eyes are closed; their faces, the bases of their ears and often their genitalia are swollen. When they are ill they come into the open and sit about, breathing slowly and often with difficulty, for several days before they die. Letters to newspapers reporting that they are "in agony" and attempting suicide need not be literally believed; nevertheless there is a very powerful and vocal humanitarian argument against spreading the infection in order to obtain economic rewards.

In order to foretell the likely future of myxomatosis in Britain, we need to know more of its method of spread and the controlling factors here and elsewhere. Thus we can better judge whether its activity in Britain should be helped or hindered.

Method of Spread

The natural disease in South America is apparently mosquito-borne. So, too, in Australia, mosquitoes seem to play a major part. They and other biting insects seem to act only as mechanical transmitters of infection—'flying pins'. In its first year there, the killing of rabbits was mostly along river-beds only, *Culex annulirostris* being the main vector. But in 1951–52 spread occurred far away from rivers, *Anopheles annulipes*, a wide-ranging mosquito, being largely concerned[3]; this species is believed to feed on rabbits in warrens underground. The seasonal incidence and character of outbreaks in Australia are quite closely linked with rainfall and associated prevalence of different biting insects.

There is little exact information as to the method of spread of myxomatosis in France. The rapidity of spread and the frequency of attack on tame rabbits suggest that a flying insect, probably a mosquito, plays a major part.

In Britain there has been no evidence of dramatic 'jumping' of infection, as in Australia, except where man has intervened. It is thus interesting that there is, as yet, no evidence that mosquitoes are playing any major part in spreading the disease in this country[4]. The fact that there is widespread infection in wild rabbits but only a few authentic infections of tame rabbits is also evidence against participation of a winged vector. On the other hand, rabbit fleas (*Spilopsyllus cuniculi*), which do not occur in Australia, may well be acting as a vector here. I have found, as have others, that among rabbits kept free from ectoparasites, cage-to-cage infection in the laboratory has not occurred. Fleas are abundant on wild rabbits and with warmer weather congregate more on the head where myxomatous lesions chiefly occur. Though specific parasites of rabbits, they are occasionally carried on birds and presumably could in this way help in wider spread of infection[5].

Changes in Rabbit-virus Relationship

A relationship in which a parasite kills more than 99 per cent of its hosts is not likely to be stable. In associations of long standing, host and parasite become adapted to living together, as is the case with myxoma virus and the South American tapeti. An adjustment in this sense is sure to take place elsewhere. Development of inherited resistance is likely to take a long time in rabbits—even they are slowly breeding beings in comparison with a virus. There is so far little evidence that offspring of recovered rabbits are resistant. On the other hand, there have been found in Australia virus strains of lowered virulence, taking longer to kill and killing only 90 per cent instead of more than 99 per cent. Rabbits living longer remain infectious longer and the virus can therefore spread more readily, so that one with a tendency to kill more slowly has an evolutionary advantage[6]. So far there is little or no evidence of emergence of an attenuated virus in Britain, or, so far as one knows, in Europe. Indeed, the apparently more stable European strain is being used for re-introductions of virus into Australia.

Human Intervention and Myxomatosis

In Australia, even where the kill of rabbits is very high, the disease passes on, and surviving rabbits begin to breed. The new generation of rabbits will not be immune and to keep them down and, as the Australians say, to "back up the virus", other destructive measures are being used and, when needful, virus is re-introduced. Thus, myxomatosis is greatly helping Australian economy; but to take full advantage of it, scientific "backing-up" is being used on a very large scale.

In the British Isles, myxomatosis has now reached nearly every county of England and Wales and a number in Scotland and Ireland. Its incidence, however, is very patchy. In most counties one can walk for miles and see plenty of healthy rabbits and not a single diseased one. The total destruction of rabbits must be still trivial. The poor summer of 1954 may have militated against spread by 'flying pins', and a warm September might yet alter the picture. It seems likely, however, that myxomatosis, except perhaps in south-east England, is only here and there. Things might remain like this into the indefinite future, with the disease spreading naturally or otherwise from farm to farm, parish to parish and back to its starting point as new susceptible rabbits grow up. There might well be no striking effect on rabbit numbers, except indirectly as the existence of the disease affected the trapping industry and the taste of the people for rabbit-meat; these factors might leave us in many areas with more rabbits rather than less. Further, we should still have the disease with us, with local epidemics killing the rabbits in hundreds in its highly unpleasant fashion. If such should indeed be the outcome, we should have all the disadvantages of myxomatosis with no compensating economic gain. It might then be cogently argued that we should follow the Australian example, introduce the disease simultaneously into areas of convenient size and "back it up" intensively. The rabbit population might thus be drastically reduced with a resultant gain not only to our economy but also to our very natural wish to inflict the least possible suffering on the rabbits. Maximum suffering over a long period would be caused if the disease kept going spontaneously round the country like a travelling circus. Scientists did not introduce the disease into Britain, and no official or unofficial action of man can possibly stop it. What the disease will accomplish 'on its own' we cannot yet foresee.

NUCLEAR AND MESON PHYSICS

INTERNATIONAL CONFERENCE IN GLASGOW

THE International Union of Pure and Applied Physics and the United Nations Educational, Scientific and Cultural Organization sponsored a conference on nuclear and meson physics which was held in the Department of Natural Philosophy, University of Glasgow, during July 13–17, under the general chairmanship of Prof. P. I. Dee. A wide range of topics was covered, and more than one hundred papers were presented. In these circumstances it is impossible, in a short review, to do justice to, or even mention, all the contributions.

The opening session was on nuclear forces and nucleon scattering. The present state of knowledge in this field was surveyed by Prof. H. S. W. Massey, who stressed the need for more work on the very light nuclei, in addition to that on proton–proton and proton–neutron scattering, to try to gain some direct evidence on the presence or absence of many-body forces. The recent work on nucleon–nucleon scattering at Harvard and Brookhaven was described by Prof. N. F. Ramsey; the extension of proton–proton scattering experiments to high energy has shown that the apparent constancy of the total cross-section at high energies is due to a broad flat minimum in the range 200–400 MeV.

In the angular distribution of proton–deuteron scattering at 20·6 MeV., described by Dr. D. O. Caldwell, a minimum at small angles has been found, due to the interference between the Coulomb and nuclear scattering. This interference should enable data to be fitted with a unique set of phase shifts and decide between the two sets which both fit the earlier data. Work was also reported from several laboratories on the scattering of polarized nucleon beams.

An account of the present status of the meson theory of nuclear forces by M. M. Levy and R. E.

Marshak was presented by Prof. Marshak, who emphasized the different approximations used in current treatments. He made it clear that, although the present theory includes many of the observed features of nuclear forces, further developments towards a fully non-static approximation are required.

The sessions on nuclear data and nuclear models was opened with review papers: by Prof. J. A. Wheeler on nuclear models, and by Prof. S. Devons on the experimental determination of energy-levels. Prof. Wheeler dealt with the work currently in progress on different aspects of the problem and, in particular, described the work of K. A. Brueckner. This considers a test nucleon passing through an infinite nuclear medium. The wave describing the nucleon is scattered by each of the moving centres in the medium, the forward-scattering amplitudes adding coherently to the primary wave. No elementary law of interaction enters the calculations—only the phase shifts which describe the nucleon–nucleon scattering up to 100 MeV. The present experimental information, however, is not sufficiently complete to exploit this approach.

Prof. Devons emphasized the great theoretical and experimental advances of the past few years, and pointed out that in some cases theory has now outstripped experiment. He instanced the small differences in the Coulomb energy for corresponding levels of a T-multiplet (which have considerable interest, but are not always known with great accuracy) and the low-lying rotational levels of some heavy nuclei which need to be determined with the highest precision. Of great interest was his description of the measurement at the Imperial College of Science and Technology, London, of the reduction of the Doppler shift as a recoil particle passes through slowing-down materials. This method promises to fill the gap in the lifetime measurements of radiative transitions. Of the numerous interesting experimental papers read at this session, that of Dr. W. W. Buechner describing the work at the Massachusetts Institute of Technology, using a magnetic spectrograph as a particle analyser, most emphasized the great accuracy attainable with present-day techniques. A theoretical paper of particular significance was that of J. P. Elliot and B. H. Flowers, who derived the even parity, low-lying levels of mass-19 nuclei. These are assumed to arise from configurations of the form $\Sigma d^{3-x}s^{x}$ ($x = 1$, 2 or 3). By using essentially only one free parameter, the positions and spins of these levels are predicted and show good agreement with the somewhat sparse experimental data. Prof. V. F. Weisskopf closed these sessions with a stimulating and provocative summary of the present position. The problems he discussed included that of the effective mass of a nucleon inside the nucleus, and the possibility of the internucleon forces in nuclei being different from those between free nucleons.

Another aspect of low-energy nuclear physics was discussed at the session on photo-disintegration. The results of Dr. H. W. Koch on X-ray scattering were interpreted by Dr. U. Fano as showing that the giant resonance does not possess a detailed structure. A tentative theory of the giant resonances was put forward by Dr. D. H. Wilkinson. This explains the resonances in terms of single-particle transitions for the absorption process, and the anomalously large yield of high-energy particles and their angular distribution are predicted in terms of the same absorption process.

The field of beta- and gamma-ray transitions was surveyed by Dr. K. Siegbahn, who described the recent developments which enable extremely accurate measurements to be made. A most stimulating talk on the interaction in β-decay was given by Dr. C. S. Wu. The Fermi and Gamow–Teller components have approximately the same magnitude, and recoil experiments on helium-6 show that the latter is a tensor interaction. Preliminary results on neon-19 recoils suggest that the Fermi interaction is scalar, as favoured by other evidence. The more recent calculations which nullify the necessity for the pseudoscalar component have been confirmed in their conclusion by the direct measurement of the spin of radium E by K. Smith, who has obtained a value of 1.

The conference was divided into two halves: during the first two days nuclear phenomena not involving π-mesons directly were discussed, and the last two were mainly devoted to mesonic (largely π-mesonic) physics. The intervening day, July 15, was spent in a chartered steamer sailing among some of the lochs and islands of the Firth of Clyde; this not only allowed a view of some beautiful scenery, but also gave the delegates an opportunity for discussion, particularly valuable by reason of the rather tight programme.

Prof. H. A. Bethe opened the morning session on July 16 with a general survey of pion–nucleon interactions. He discussed the cross-sections for pion–proton scattering up to about 200 MeV. which are interpretable in terms of phase shifts for angular momentum states $P_{3/2}$, $P_{1/2}$ or $S_{1/2}$ and states of total isotopic spin $T = {}^3/_2$ or $T = {}^1/_2$. Of the three possible analyses into phase shifts, only one gives a resonance in the $P_{3/2}$ $T = {}^3/_2$ state, but physical reasons are given for this being the most plausible analysis. These results, including the low-energy P-wave scattering, are interpreted in terms of the pseudoscalar coupling theory of mesons to nucleons, using Tamm–Dancoff approximate methods. The more difficult interpretation of the photo-production cross-sections was also discussed. In this session, papers on experimental researches on pion–nucleon scattering and pion production up to energies of 1·5 BeV. were presented by Dr. R. H. Hildebrand (Chicago), Dr. J. Ashkin (Carnegie Institute of Technology), Dr. J. B. Platt (Rochester, N.Y.) and Dr. A. C. Helmholtz (Berkeley).

In a session on detailed meson theory, Prof. F. J. Dyson gave an account of the surmounting of difficulties, in the Tamm–Danooff mèthod, at Cornell. Other papers included two on the origin of spin orbit coupling in nuclei, while Dr. M. Cini reported the application of the variational method of Cini and Fubini to pion–nucleon scattering. This latter method gives a correct fit of the P-wave, though not the S-wave, phase shifts to the 'Glicksman set' of phase shifts, and seems capable of refinement by, for example, the introduction of a further variational parameter.

The afternoon of July 16 consisted of four simultaneous meetings of special interest. These were on β and γ transitions and mesic X-rays, detailed theory of nuclear models, field theory and photodisintegration (mentioned earlier).

Dr. J. Ashkin reported on measurements of the intensities and energies of X-rays from π-mesic atoms. Energy measurements of X-rays from *transitions* between outer shells, where the π^--meson nucleon interaction does not appear, gives a close determination of the π^- mass, while measurements of line shifts in inner shells where the nuclear interaction operates can be related to phase shifts in the meson–nucleon scattering. Dr. J. B. Platt reported work on the relative intensities of X-ray lines in order to find the attenuation resulting from nuclear capture from inner shells.

The field theory meeting was opened with a talk by Prof. W. Heisenberg on "Quantization of Non-linear Wave Equations"; it is proposed to introduce just one wave function for all matter, obeying a non-linear field equation. The equation

$$\gamma_\nu \frac{\partial\psi}{\partial x_\nu} + l^2\psi(\psi^+\psi) = 0$$

is taken as an example, and study of the likely commutation rules leads to the conclusion that the laws of quantum mechanics would be modified in a certain region of Hilbert space.

The conference ended on the afternoon of July 17 with a full meeting of all delegates, at which papers on heavy mesons and hyperons were presented. Dr. C. C. Butler opened the session with an excellent review of our present knowledge of heavy mesons and hyperons, and the conference closed on a high note with a paper by Drs. A. Pais and M. Gell-Mann on some theoretical speculations concerning the heavy particles, which included an interpretation of Λ^0 particles as particles of high intrinsic spin. The full proceedings of the conference will be published by the Pergamon Press.

SCIENCE, ANIMALS AND HUMANITY*

By W. LANE-PETTER
Laboratory Animals Bureau, Medical Research Council Laboratories, London, N.W.3

If I were a psychologist I might understand, and even be able to explain, why animals, and in particular certain animals, evoke an emotional response in human beings, so strong in some that it is beyond the reach of reason. We all know of the cat lovers who carry their devotion outside the limits of economy or hygiene; of the dogs who lay undisputed claim to the best armchair or the master's place on the hearth-rug; of the horses, canaries and other animals who receive more consideration from their owners than persons more nearly related zoologically and therefore having, one would think, better claims to affection. On the other hand, by taking some animals into domestication, or keeping others in captivity, man accepts an obligation to look after them, for they are entirely dependent on man for the necessities of their being. It makes it easier for us to do our duty towards our animals if we are fond of them.

Emotion, then, is bound to creep into any discussion of relations between animals and man, and it is a deep and often disturbing emotion. To ignore it is unrealistic, and to be ashamed of it unnecessary; but it should not be allowed to cloud our reason, any more than any other emotion. Such undisciplined feeling is often associated with a morbid preoccupation with brutality—a revealing word—in books and articles, on the cinema screen, in conversation and perhaps in real life, and the minutiæ of violence excite a thrill of disgust, guilty pleasure or any other emotion; but above all a thrill. There can be few normal people who are totally unaffected by the sight or image of injury, be it accidental, criminal or surgical; but in most of us that basic attraction–repulsion is clothed in reason or rationalization. So in a discussion of animals let us try to recognize the shadow of the brute within our souls and keep him chained, and let us be especially wary lest any moralizing we may indulge in be the brute tugging at his leash.

There exists a great gulf between those whose primary interest is in the welfare of animals, and the scientists who use animals in their work. It is a gulf of misunderstanding so wide that the leaders in each field are often not on speaking terms with one another, at least in public. "Callous torturer", says the humanitarian, and the scientist replies "sentimental crank". Yet the first may be a reasonable, intelligent and responsible person, and the second as deeply moved by cruelty as any of his fellows, for whom the obligation of humanity is so obvious that he does not bother to explain it. But of course he should explain what he is about, and the layman who criticizes him should listen to the explanations.

What Dr. J. Bronowski says of the nuclear scientist[1] has a more general application. The scientist, he says, ". . . has one special responsibility . . . of enlightenment in scientific matters . . . the responsibility of knowledge, not of power . . . to illuminate for all men the choice which his work offers them. . . . Outside his laboratory, his task is to educate us in what goes on inside it, and to give it a meaning for us. In a world in which statesmen as much as voters are ignorant of the simplest implications in science, this is a formidable responsibility . . . [the scientist] has no other choice to-day but patiently to become a teacher, in a world in which distrust and prejudice are free. . . . There is no alternative to an informed public opinion: and that can exist only where scientists speak to voters, and voters accept their responsibility, which is to listen, to weigh, and then to make their own choice".

Now this is just the reverse of the point of view that I have heard from the lips of both scientists and administrators. Let us, they have said, keep quiet about animal experiments. People do not want to hear about them, and if we direct their attention to this side of scientific activity, it will merely give stamping-ground to the anti-vivisectionists. Or, perhaps they will say, nobody bothers much about rats and mice and guinea pigs; but whatever you do, leave cats and dogs out of it; these animals to-day occupy the place in men's hearts that horses did a century ago, and we should let them lie sleeping. But is this playing fair with the voters?

We need not concern ourselves with the abolitionists who are unreservedly opposed to any sort of animal experimentation. It is possible to respect their feelings, but not their way of conducting controversy. Perhaps I may digress a little in order to show how careful one has to be in the matter of anti-vivisection propaganda. In 1948 a deputation of antivivisectionists met the Home Secretary, and cited a number of alleged cruelties. Referring to the work of Mellanby on experimental rickets[2] in puppies they quoted "animals were confined absolutely in kennels, 8 ft. 6 in. by 2 ft. 6 in., for 13 weeks. . . . These animals were most seriously attacked by mange". It seems a strange tactic to attempt to pillory work on rickets, which was at that time a major scourge, and which has now, as a result of that work, become a rarity. But on referring to the report itself we find that the purpose of prolonged confinement was to investigate the part played by exercise and confinement in the production of rickets, and that the animals so confined "grew well and kept in perfect condition". The animals attacked by mange were the subjects of an entirely separate experiment, and "because of the severity of the disease, the experiment was concluded".

---

* Substance of a paper read on September 6, 1954, before Section D (Zoology) of the British Association meeting at Oxford.

The same deputation referred to some work done at Cambridge in 1931 by Florey and Webb[3], in which the effects of mustard oil on various tissues of the cat were examined. They said that the work was done under "a narcotic, chloralose", and that the experiments lasted from 3½ to 8½ hours. Now, the use of chloralose as an anæsthetic is limited to non-recovery experiments, and this fact is well known to scientists, but not apparently to their critics; and, although it was not specifically mentioned anywhere in the paper describing the experiments, the cats never felt any pain at all, for they were unconscious before the experiments started and never regained consciousness.

While the scientist's main job is to get on with his work, his opponents can spend all their time and resources on attacking him. Moreover, to answer ten words of accusation, however preposterous, may take a hundred words in reply.

Antivivisectionists have not yet succumbed to the advance of medical knowledge; but they are of no great consequence, although it is still possible for them to be a real nuisance. They should certainly not be allowed to inhibit scientists from expressing humanitarian views on animal experimentation. But what can one say when the Royal Society for the Prevention of Cruelty to Animals, the most influential body of organized animal welfare, whom we should all, I hope, wish to support and see prosper, asks "Why not endeavour to reduce the vast total of animal suffering in the laboratories? Until the animal experimental section of the scientific world shows some sign of concern in this direction, the R.S.P.C.A. would fail in its duty if it did not sound the drum of alarm"[4]. How have the scientists so come to neglect their duty of informing the public of what they are about that these questions can in all seriousness be asked?

Experiments on animals have led, and may be confidently expected in the future to lead, to great benefits to man and to animals, with all that that implies in the relief of suffering and the saving of life. The cost is the infliction of some pain on a number of animals that are neither consenting nor direct beneficiaries. Is this not, we are asked, "to do a little wrong" in order that one may be enabled "to do a great right"? Is it not the old argument of the end justifying the means?

Now these questions beg one assumption, that to inflict pain, in itself, is always wrong. But is it? Man, by entering into the arrangement of domestication, assumes the power of life and death over his animals. Civilized man also assumes the responsibility of avoiding cruelty to these same animals, and Great Britain has a good record in this respect. Pain is inseparable from life itself, and the occasional infliction of it from our dealings with each other and with our animals. But the infliction of pain is not synonymous with cruelty. The Shorter Oxford English Dictionary defines cruelty as "a disposition to inflict suffering: delight in or indifference to another's pain", and here is the real point. In the words of Lord Wright in the House of Lords on July 2, 1947, ". . . it is impossible to apply the word cruelty to efforts of the high-minded scientists who have devoted themselves to vivisection experiments for the purpose of alleviating human suffering . . ." Those who, for whatever motives, inflict pain on animals and are indifferent to the fact, are cruel, and deserve condemnation. But a word of caution is necessary here. Because a scientist, in reporting his work, does not explicitly state that he was aware of the pain he was inflicting, that he did it with reluctance and was careful to minimize it, it must not be assumed that this was not so. He has a right to be regarded as a humane person unless he gives evidence to the contrary. Moreover, as we have seen, scientific language is too often indigestible material for the layman, and technical descriptions of experimental procedures can make hair-raising reading for him. But in all the responsible examinations of alleged horrors perpetrated, in Great Britain at least, the scientist has been vindicated.

Scientists do not like being called callous blackguards, and, though individualists by training and inclination, they can show a surprising solidarity when unfairly calumnied. As Major Hume, of the Universities Federation for Animal Welfare, says, ". . . public opinion in scientific circles, which in the eighteen seventies befriended animals as a matter of course, has until recently been rendered allergic to any reference to the prevention of cruelty. Then animals enjoyed the open patronage of scientists as such, but subsequently they were largely deprived of it by the polemical intemperance of those who intended to act as their champions"[5]. One reads some personal feeling between these lines, for in some of its activities U.F.A.W. has not been immune from criticism by scientists, myself among them. But the point is well made. To-day we can state fearlessly what is generally accepted, that painful experiments should have a worth-while object and should be conducted with every effort to minimize the pain; and that pain beyond a certain level in severity or duration or a combination of both is never justifiable. To state such a principle requires that its observance be demonstrated, and this means bridging the gulf between scientists and animal protectionists.

Is the "total of animal suffering in laboratories" so "vast"? How are scientists to convince those who are open to conviction that this is a gross exaggeration? I think it very reasonable that laymen should want to satisfy themselves on this score, and understand why and how experiments, when they are painful—and most of them are not—are carried out. It is in fact one of the main functions of the Research Defence Society to explain, in language intelligible to the layman, what we all owe to animal experiments, and what safeguards exist against the unjustifiable exploitation of animals. Their journal contains some interesting accounts of the conquest of many diseases and deserves wider reading than it gets. But more, much more, needs to be done.

As a matter of fact, scientists themselves have anticipated the R.S.P.C.A. in showing "some sign of concern". As long ago as 1870 the British Association appointed a committee, which reported in 1871, "to consider the subject of Physiological Experimentation"[6]. The British Medical Association also turned its attention to the controversy at about the same time, and reported in like vein. Earlier still, the giants of the biological world, men like Charles Darwin and Thomas Huxley, had expressed their concern about the possibilities of cruelty in laboratories. All this led directly to the Act of 1876, which controls painful experiments on animals in Great Britain, and was supported by most scientists. Under this Act, which has been and still is faithfully observed, all severely painful experiments are carried out while the animal is completely under the influence of an anæsthetic; if severe and enduring pain follows on recovery, life is destroyed forthwith. What more is wanted, if we are not to abandon the most fruitful method of medical research so far devised?

Prof. Robert B. Lawson, writing about animals in pædiatric research, says "... one cannot escape feeling the intense debt due the research animal. The way in which each type of investigation requires a particular animal is particularly striking. Rats play a key role in one study—mice in another—and the dog in a third. Rarely can one take the place of the other. We are indebted to all research animals for the tremendous advances in medical science that have made this generation of children healthier, bigger, and with more promise, than ever before"[7]. In a recent symposium on the design of animal houses, the chairman, Dr. Parish, said, "It is a good thing that laboratory workers themselves wish to improve the living conditions of animals and thus repay the debt ..." Indeed, the progress that has been made in recent years in the housing, feeding, care and management of laboratory animals is quite remarkable, and owes everything to the initiative of the scientists.

It is a symptom of the times to try to make scientists the scapegoats for that which disturbs the public conscience. They are not the high priests of a secret cult, dealing in matters not to be revealed to ordinary men and women; neither are they mental acrobats and moral imbeciles. They are as good and as bad as the rest of the community, but no more indifferent to the sufferings of others than farmers or financiers.

If this tragic misunderstanding is to be got rid of, scientists must take time off to explain the mechanics and implications of their work and show that they respect the feelings, even the misgivings, of the humanitarians; and the public must modify its "Scientists—I'd like to drown the lot" attitude. An example of what mutual goodwill can achieve is to be seen in Vancouver, British Columbia, where, by friendly agreement on both sides, the local Society for Prevention of Cruelty to Animals supplies to the medical school unwanted, unclaimed animals, which would otherwise be destroyed. In a nine-point agreement, the conditions in which this surrender of unclaimed strays operates are laid down, and the medical faculty has been only too happy to abide by them. As a result of the agreement, the medical school gets the animals it must have, it allows the S.P.C.A. to visit its animal quarters, and indeed looks to that enlightened organization for advice and help in maintaining the best possible conditions for its animals. An atmosphere of co-operation exists which is a help, and a credit, to both sides.

It is worth examining this arrangement more closely. The animals supplied to the medical school may only be used for non-recovery experiments, that is, they are anæsthetized before use, and never recover consciousness; and they must be used within forty-eight hours of being handed over. All long-term experiments are done on animals obtained elsewhere.

Only dogs otherwise destined to be destroyed may be handed over, and these must not include any brought by their owners specifically for destruction, nor any bearing identification marks. The animals must be kept two days beyond the legal claiming holding period before being handed over. The S.P.C.A. inspectors may witness experiments and have access without appointment to records and to animal premises. No animal handed over by the S.P.C.A. ever suffers any pain at all; it has a painless death under anæsthesia. At the same time, the S.P.C.A. can and does satisfy itself that all the animals used are well cared for. This shows how far mutual trust and co-operation can go.

There can be no objection on humanitarian grounds to any animals, including cats and dogs, being used for non-recovery experiments. If objections are raised, they must be based either on an aversion to animal experiments on principle, whether or not they are painful; or on a profound mistrust of the scientist. The first alternative leads one into such a philosophical morass as few if any of us could escape from. I am inclined to think that the second alternative, mistrust of the scientist, is the real obstacle to co-operation. Sentiment comes into this question, and it is no use pretending we can keep sentiment out. It should not, however, be allowed to ride us. Scientists would prefer to obtain the animals essential to their work in ways which remove the danger of their being sold a stolen pup, and to have impartial people satisfy themselves about the propriety and humaneness of their work.

I would not like to leave the impression that to get scientists and humanitarians sitting around the conference table has, for the scientist, no more interest than to obtain more cats and dogs more easily. If that were one of the results, so much the better; but the issue is much larger.

To-day we have a duty to pursue medical research by all legitimate methods, and one of those methods is the use of animals. We also have a duty to be considerate in our dealings with animals, and the two duties are not incompatible. Can we not, like the British Columbians, explore the no-man's-land of misunderstanding and discover instead the common ground of humanity?

OBITUARIES

Dr. Herman A. Spoehr

By the death on June 21 of Dr. Herman A. Spoehr, at the age of sixty-nine, plant physiology has lost one of its best known and most distinguished research workers and exponents.

Herman A. Spoehr was born in Chicago on June 18, 1885, and was educated at the University of Chicago, where he took his bachelor's degree in 1906. After working for a time in the laboratories of Emil Fischer in Berlin and L. Maquenne in Paris, he returned to Chicago, where he worked with the well-known sugar chemist, J. U. Nef, and where he took the degree of Ph.D. in 1909. In the following year he joined the staff of the Carnegie Institution's Desert Laboratory in Tucson, Arizona, where he remained for ten years. During this period he published a number of papers which established his reputation as an original and critical investigator. Among his more important publications of this period may be mentioned those dealing with the mechanism of photosynthesis. At that time the theory that formaldehyde was an intermediate product in photosynthesis was very largely accepted. Spoehr, on repeating under properly controlled conditions the experiments which were supposed to provide the evidence for this theory, was unable to find the slightest indication of formaldehyde production, and Spoehr's work was no doubt largely responsible for the ultimate abandonment of that theory. Perhaps the most important of Spoehr's publications during his time at Tucson was his monograph "The Carbohydrate Economy of the Cacti", published by the Carnegie Institution in 1919.

In 1920 Spoehr moved to the Carnegie Institution's Coastal Laboratory at Carmel, California, followed in 1929 by a move to Stanford University, which in that year took over the housing of the Division (now the Department) of Plant Biology which had been created in the previous year with Dr. Spoehr as its first chairman. While at Carmel, among other publications, he produced two of particular importance. One of these, jointly with J. M. McGee, was "Studies in Plant Respiration and Photosynthesis", published by the Carnegie Institution in 1923, the other his well-known book on photosynthesis published in 1926.

For a short time in 1930–31 Dr. Spoehr was director of the Natural Sciences Division of the Rockefeller Foundation in New York; but in the latter year he returned to Stanford to resume the chairmanship of the Division of Plant Biology. He retired officially in 1950 but continued thereafter to work in the laboratory that he had directed for so long.

Throughout his life in the Division of Plant Biology Dr. Spoehr's main scientific interests continued to lie in photosynthesis and related matters. Particular mention may be made of his successfully bringing to maturity albino maize plants, while in later years he was much interested in the question of applying the results of research in photosynthesis to increasing the food supply of the world. This led to the idea of the culture of algae on a large scale for the use of food, and by 1947 the possibility of cultivating *Chlorella* on a large scale for this purpose was taken seriously and a preliminary analysis of the problems involved was prepared by Spoehr and H. A. Milner and published in the Carnegie Institution Year Book for 1948. Although preliminary work on the subject at Stanford Research Institution was ended in 1950, it has been continued elsewhere, and the recent (1953) Carnegie Institution Publication on "Algal Culture", edited by J. S. Burlew, indicates in no uncertain way that further investigation on the problem is proceeding vigorously.

During the Second World War the laboratory of which Dr. Spoehr had charge concentrated on the study of antibiotics from chlorophyll-containing organisms.

As well as by his direct contributions to plant physiological research and literature, Dr. Spoehr served the cause of science in other ways. He was a member of the board of directors of the Forest Genetics Research Foundation, a member of the scientific committee of the Board of Managers of the New York Botanical Garden, a trustee of the California Section of the American Chemical Society, a member of the executive board of the Save-the-Redwoods League and for a time chairman of the editorial board of Annual Reviews, Inc. He was a member of the American Philosophical Society, the American Academy of Arts and Sciences, an honorary member of the Linnean Society of London and the Deutsche botanischen Gesellschaft of Berlin. He was awarded the honorary degree of doctor of science of the University of Chicago and he received from the same University one of its Distinguished Alumni Awards in 1943.

Dr. Spoehr is survived by his widow, a son Dr. Alexander Spoehr, the anthropologist and director of the Bernice P. Bishop Museum in Honolulu, a daughter, his mother and a brother.

In preparing this notice of Dr. Spoehr I have been greatly helped by information provided by Dr. J. H. C. Smith and Dr. C. S. French, the present director of the Department of Plant Biology of the Carnegie Institution of Washington.

WALTER STILES

Dr. A. M. Turing, O.B.E., F.R.S.

ALAN TURING was born on June 23, 1912, and was educated at Sherborne and King's College, Cambridge. He was made a Fellow of King's in 1934; he submitted his fellowship dissertation—a version of the central limit theorem for the normal distribution—four months after being placed as Wrangler in the Mathematical Tripos. During his first years of research he worked on a number of subjects, including the theory of numbers and quantum mechanics, and started to build a machine for computing the Riemann ζ-function, cutting the gears for it himself. His interest in computing led him to consider just what sort of processes could be carried out by a machine: he described a 'universal' machine, which, when supplied with suitable instructions, would imitate the behaviour of any other; he was thus able to give a precise definition of 'computable', and to show that there are mathematical problems the solutions of which are not computable in this sense. The paper which contains these results is typical of Turing's methods: starting from first principles, and using concrete illustrations, he builds up a general and abstract argument. Many years later he used an elaboration of the same ideas to prove the unsolvability of the word problem in semi-groups with cancellation.

In 1936 he went to Princeton for two years; he worked on group theory and logic, receiving his Ph.D. for a dissertation on "Ordinal Logics". In this he showed that when transfinite induction is used in logic for proofs and definitions, it is not the ordinal up to which induction runs that has significance, but rather the particular way in which that ordinal is described.

He was awarded the O.B.E. for the work he did during the War, and after it he was invited by the National Physical Laboratory to direct the design of an electronic digital computor (which he christened "The Automatic Computing Engine"). Although the theoretical aspects of its design were his chief concern, he was also keenly interested in its electronics; and while the final construction was in progress he turned to long-term problems, considering how machines might be made to learn by trial and error and the ways in which they could be compared with human brains.

In 1949 he was made deputy director of the Computing Laboratory at the University of Manchester, where work on an electronic computor had just started. He was elected Fellow of the Royal Society in 1951. His last work was a mathematical theory of morphogenesis; the main idea was to show how an originally uniform distribution of interacting substances may, as a result of diffusion, develop a strongly marked pattern. He had already published a version of the theory for distributions around a ring, and was at work on the case of a cylinder; using the machine to solve the appropriate differential equations, he was hoping to be able to exhibit the spiral patterns based on the Fibonacci series which are so frequently found in plants.

The marks of Turing's genius were his originality, his ability to control abstract thought by concrete illustration, and his preference for always working things out for himself. The freshness of his mind, his love of inquiry, and his relish for the comic, made him a lively and stimulating companion.

R. O. Gandy

Prof. C. R. S. Tenniswood

Charles Robert Sidney Tenniswood, professor of chemistry in Makerere College, University College of East Africa, died on May 22, following an accident in which his car skidded in the grounds of the College. At the time of his death, he was forty-seven and had been head of the Makerere Department of Chemistry for some nine years.

Charles Tenniswood graduated from King's (then Armstrong) College in the University of Durham with first-class honours in chemistry in 1927, being awarded the Freire-Morreco Medal and Prize for experimental work in the final year. The following year he was placed in the first division for the diploma in theory and practice of teaching before going on to three years of postgraduate research in organic chemistry under Prof. S. R. Clemo. His M.Sc. was awarded for a thesis entitled "Studies in the Synthesis of Bridged-Ring Compounds of the Quinuclidine Type", and he published papers on alkyl derivatives of ethyl malonate and ethyl cyanoacetate and on the lupin alkaloids.

Leaving the University of Durham in 1932, he was appointed head of the Chemistry Department of the Wandsworth Technical Institute, London, and then started a career of teaching which, except for the war years, was to last until his death. During 1941–44 he was seconded to the Ministry of Supply for work in the field of projectile development.

As a result of the De la Warr Commission in 1937, Makerere College, at Kampala in Uganda, had been planned for development to a university college serving all the territories of British East Africa; but the implementation of these proposals was delayed by the War. When Tenniswood arrived at the beginning of 1945, the level of teaching was of school standard and the teaching facilities consisted of one small and poorly equipped laboratory. At the time of his death nine years later, he had seen his first batch of degree students successful in their London B.Sc. Examination and had brought almost to completion the first of the new laboratories, which are giving East African undergraduates facilities in chemistry quite as good as they could enjoy in a British university. It was natural that senior members of the staff should have to bear a heavy burden of administration in the early days of a university. Tenniswood made invaluable contributions in this direction, with his great care for detail and unlimited energy. At the time of his death he was dean of the Faculty of Science and for several years had represented the Academic Board on the College Council. By his students he will probably be best remembered for the great enthusiasm that he brought to the teaching of chemistry, an enthusiasm which spared no pains to provide an interesting course and which infected his hearers with his own love of his subject. His many other duties had prevented him bringing to conclusion the researches that he started in East Africa. His earlier interest in plant alkaloids led him to investigate some of the many unknown active plant materials which have been used for years in native medicines.

Tenniswood's death is felt no less by his colleagues than by his students. His integrity and forthrightness were appreciated in personal dealings as well as in the many boards and committees on which he served, and he had a wide range of friends both in the College and in life outside. Growing colleges such as Makerere can ill afford to lose men of Tenniswood's loyalty and calibre, and his untimely death is keenly felt by all concerned.

Ralph F. Naylor

Dr. J. W. Fisher

Dr. J. W. Fisher, whose untimely death at the age of fifty-three was recently reported, was a member of the Royal Naval Scientific Service, having served with the Admiralty since 1939. He studied physics and mathematics in the University of London, where he obtained his Ph.D. in 1924. Having completed his postgraduate studies at Gottingen and Munich, he studied medicine and took his M.R.C.S. and L.R.C.P. and became house physician at Westminster Hospital. Before joining the Royal Naval Scientific Service he was engaged on research and exploration in Britain and in India on behalf of the Anglo-Iranian Oil Co.

While in the service of the Admiralty, Fisher's work was mainly directed to the solution of a number of highly intricate problems relating to the propagation, generation and reception of sounds in the sea. He brought to these problems a wide knowledge of basic physics and quite outstanding mathematical ability, coupled with the power of seeing the basic problem and to approximate—a gift which raises mathematics from a technique to a fine art. He held, with Stokes, that series solutions are devoid of elegance and showed great ingenuity in reducing his solutions to neat closed forms. The outstanding quality of his theoretical and experimental work was recognized when, in 1949, he was awarded special merit promotion to the rank of senior principal scientific officer by the Interdepartmental Scientific Panel.

Fisher had a gift for terse and pithy expression often combined with an amusing use of analogy based upon his medical experience. He had many interests apart from his scientific work, the most notable being an authoritative knowledge of antiques. He specialized in Chinese works of art—in particular, jade and carpets. With all this, he still found time to engage in farming on a small scale.

Men like Fisher are rare in any walk of life and his loss is much felt by his colleagues both in the Royal Naval Scientific Service and outside.

NEWS and VIEWS

Zoology at Bedford College: Prof. H. Munro Fox, F.R.S.

PROF. H. MUNRO FOX, who is just retiring from the professorship of zoology in the University of London at Bedford College, has occupied this chair since 1941; previously he had been Mason professor of zoology in the University of Birmingham from 1927 until 1941. After graduating in zoology from the University of Cambridge he joined the staff of the Imperial College of Science and Technology, London, in 1913, and after five years of war service returned there in 1919. Afterwards he was lecturer in biology at the School of Medicine, Cairo, during 1919–23. He then returned to Cambridge as a Fellow of his old college, Gonville and Caius, and also held the Balfour Studentship during 1924–27. During this period he organized and led a zoological expedition to the Suez Canal.

Prof. Fox's earlier investigations were in the field of marine biology and while in Cairo he studied the reproductive cycle of *Centrechinus setosus*, which, in the Red Sea, shows a well-marked lunar rhythm. The observations on this sea-urchin and other animals and plants showing supposed lunar periodicities were summarized in his book "Selene, or Sex and the Moon". His main interests, however, have been in the field of experimental zoology and for many years he has specialized in the study of animal pigments, more particularly the respiratory pigments of invertebrates. His researches and many publications in this field and also on respiratory movements in Polychaeta, Insecta and more recently *Daphnia*, either alone or in collaboration with his students, have opened up a very wide field of research. Prof. Fox has been the editor of *Biological Reviews* since 1926 and has taken a very active part in the promotion of international relationships among biologists. After the Second World War he visited various European universities on behalf of the Royal Society, and helped in the re-establishment of the International Union of Biological Sciences, and after being secretary of the Union for some years was president during 1950–53. He also served for five years on the Advisory Council of the Department for Scientific and Industrial Research. In 1953 he was appointed Fullerian professor of physiology in the Royal Institution.

Chemical Pathology at St. Mary's Hospital Medical School, London: Prof. A. Neuberger, F.R.S.

DR. A. NEUBERGER, of the National Institute for Medical Research, has been appointed to a University chair of chemical pathology tenable at St. Mary's Hospital Medical School, London. Dr. Neuberger, who is forty-six years of age, holds the degree of M.D. (Wurzburg) and Ph.D. (London). He held a Beit Memorial Fellowship during 1936–40 and carried out research work at University College Hospital Medical School, London, until 1939. He continued his researches in the Biochemistry Department of the University of Cambridge until 1942 and has since been a member of the scientific staff at the National Institute for Medical Research. In 1945 he was adviser to the Medical Directorate, G.H.Q., Delhi. He was awarded the Julius Mickle Fellowship of the University of London in 1946. He has been a member of the editorial board of the *Biochemical Journal* since 1947 and its chairman since 1952. Dr. Neuberger has worked on a wide range of topics in the chemistry and biochemistry of amino-acids and proteins. His earlier researches were concerned with the use of dissociation constants for structural diagnosis in the amino-acid and protein field; this method was later used by him in a study of the structure of penicillin. In the amino-acid field he has been concerned with stereochemistry, in particular that of hydroxyproline, and with metabolic and nutritional aspects. He is an expert on biochemical genetics and has a special interest in the metabolic abnormality known as alcaptonuria. Recently, he has become interested in the problem of porphyrin biogenesis and has made important contributions to our knowledge of congenital porphyria. He is also engaged in the study of the biosynthesis and metabolism of collagen.

Committee of Public Accounts: Research Expenditure

THE Committee of Public Accounts for the session 1947–48 recommended that the expenditure on the Vote for the Department of Scientific and Industrial Research, among others, should be covered by statutory authority other than the annual Appropriation Act, and, in evidence before the Committee in the following session, the Treasury promised to take the first convenient opportunity to embody the functions of the Department of Scientific and Industrial Research in a statute. No such opportunity, in the Treasury view, has yet arisen; and the Committee, in its third report for the session 1953–54 (pp. 44. London: H.M.S.O., 1954. 1*s.* 6*d.* net), expresses the opinion that, in view of the years that have elapsed since the Committee of Public Accounts first recommended legislation, and the expansion of the Department's expenditure during that period, the necessary Bill should be prepared at once, ready for immediate introduction when any opportunity presents itself. In commenting on expenditure, estimated at £213,000, on the construction of a new fishery research vessel for the Torry Research Station of the Department, the Committee points out that five other departments or grant-aided bodies are engaged on fishery research and have provided themselves with a total of twelve research vessels for various purposes, but that it was not clear how the activities of these departments and bodies and the Department of Scientific and Industrial Research are co-ordinated. The Committee is not satisfied that there is no overlap of functions and recommends further inquiry by the Treasury. There is also a comment on the cost of construction of the Mechanical Engineering Research Station at East Kilbride, for which originally £1,000,000 was provided in the 1949–50 estimates, increased to £1·5 million, provisional in 1950–51 and 1951–52, reduced to £1,264,600 in 1952–53 and increased to £2 million in 1953–54, which has now been set as an upper limit. The Committee is satisfied that the Treasury exercised close control over the constituent parts of schemes of this kind, but, though critical of the way in which estimates and ideas developed as the work proceeded, the Treasury made no comment on what may well have been the more important factor in a time of rising costs—the effect of Government retrenchment and the consequent delay in executing the scheme.

University Grants

WITHOUT advancing any fresh reasons in its third report for the session 1953–54, the Committee of Public Accounts again presses for the inspection of the books and accounts of the universities relating to expenditure of non-recurrent grants by the Comptroller and Auditor General. The Committee is unconvinced by the Treasury objections as detailed in the special report last February (see *Nature*, 173, 383; 1954), although it welcomes the appointment of a special committee of four to examine the universities' methods of contracting and of recording and controlling expenditure. Nevertheless it recommends that the matter be considered afresh by the Committee for the next session, and meanwhile it also recommends that the Comptroller and Auditor General should in future have access to the papers and records of the University Grants Committee relating to non-recurrent grants and also those which contain requests from the universities for assistance and the record of the consideration of them by that Committee. This persistent attempt to subject to close control expenditure which has been deliberately made the responsibility of a non-government institution, for reasons which are generally understood and approved, is disturbing. The proposals endanger an administrative device primarily designed to preserve the ancient freedom of British universities. Admittedly, the device will only endure so long as its value is clearly understood and approved, in Parliament and outside; but could not the Parliamentary and Scientific Committee usefully look into the question why academic freedom is subjected to this sustained attack by a committee of members of Parliament appointed primarily to ensure that the Government is not wasting public money and, secondly, to ensure that public money is not wasted by independent bodies?

Earthquake near Orléansville, Algeria

In the early hours of September 9, an earthquake occurred with an epicentre near Orléansville in Algeria. Most of the buildings in the town were damaged and many of them collapsed entirely. The Hotel Baudouin and two other hotels, the sub-prefecture, a college, two blocks of nine-story workers' flats, the hospital and the railway station were destroyed immediately. The cathedral in the market-place and the Church of Saint Reparatus dating back to the fourth century were badly damaged; and part of the jail collapsed, killing ten prisoners. Almost the only large building which escaped damage was the mosque. Nine out of every ten houses in the town were rendered uninhabitable. Telephone and telegraph communications were interrupted, gas mains were torn out, and roads and railways in the neighbourhood were rendered useless. The villages of Ponteba and Vauban were reported heavily damaged and other villages in the area were in ruins. Altogether devastation was caused over an area of some forty square miles from Ténès in the north, southwards, and from Miliana in the east, westwards. The 160-ft. wall of the Oued Fodda dam was cracked, but was quickly repaired, though a main irrigation duct was dislocated and this latter caused considerable flooding. The smaller Lamartine dam is reported to have collapsed, also causing flooding. The shock was felt in Algiers but caused no damage there. Altogether the damage is estimated at four million pounds. There were more than 1,250 killed and some 2,000 injured in the district. Orléansville was a town of about 22,000 inhabitants.

The shock was recorded at many observatories. At the Royal Observatory at Edinburgh, *eP* was registered at 01h. 09m. 15s. G.M.T. and *iS* at 01h. 12m. 52s. G.M.T. There appears to be a distinct possibility that the shock was double, and that an aftershock was recorded on the Edinburgh seismogram in the coda of the first shock. This would make the initial time of the main earthquake 01h. 04m. 49s. G.M.T. The depth of focus was normal and there were large surface waves. Algiers Observatory registered sixty-nine tremors in the twenty-four hours following the main shock, fifteen of them being strong. According to records collected by Prof. J. P. Rothé and Mme. A. Hée, of Strasbourg, earthquakes are by no means uncommon in Algeria. The line of orogenic activity stretches from Gibraltar, along the Rif in Morocco and the Little Atlas mountains in Algeria to Sicily and thence to the Apennines in Italy and to the Alps. The epicentres in Algeria lie on the principal anticlinal axes. Between the years 1790 and 1949, fifty-four earthquakes originated from a focus with epicentre some fifty kilometres to the east of Orléansville, and in the same period thirty-eight shocks occurred which had another epicentre some twenty-five kilometres north-north-west of Orléansville. The region most susceptible to earthquakes in Algeria appears to be that immediately to the south-south-west of Algiers.

Silver Jubilee of the Indian Ceramic Society

The Indian Ceramic Society was inaugurated in the Banaras Hindu University on April 15, 1928, by the late Mahamana Pandit Madan Mohan Malariya, founder of the University; the silver jubilee therefore fell last year but, for various reasons, could not be celebrated until February 1954. The celebrations included the delivery of a presidential address, the reading and discussion of papers on the ceramic raw materials of India, and the opening of the Society's new headquarters within the Glass and Ceramics Department of the University. Prof. W. E. S. Turner was the chief guest during these celebrations. In his presidential address, Dr. Atma Ram described the efforts that led to the foundation of the Society and its early struggle for recognition. While discussing future policy, Dr. Ram commented on the great progress made during the past thirty years in ceramic science and in mechanization within the industry; he thought it equally important that the general outlook on matters of organization, planning and personnel had also progressed. He emphasized the need for caution in adopting mass-production methods in a country such as India, where consumption of many of the articles that would be produced is at present low. The symposium on ceramic raw materials was organized jointly by the Society and the Central Glass and Ceramic Research Institute. Its objects were to make an appraisal of the domestic resources of the raw materials needed by the Indian ceramic industry and to examine methods for their preparation and purification.

Geophysical Conference in South Africa

A successful conference on geophysical subjects was held during July 19–22 at the University of the Witwatersrand, Johannesburg, under the auspices of the Bernard Price Institute of Geophysical Research. The field covered recent determinations of the ages of rocks and their geological implications (eight papers), geodesy (four papers), crystal structure of the earth, including seismological and gravity investigations (eleven papers), geomagnetism (four papers), the mechanical properties of rocks, including the phenomena of rock bursts (five papers), the earth's heat and its origin (five papers), the interior of the earth (four papers) and geophysical prospecting (four papers). Nearly a hundred scientific workers and interested persons from South Africa attended the conference. A number of visitors were from neighbouring British Protectorates and the Belgian Congo, and from farther afield came Dr. Francis Birch (Harvard University), Dr. Robert Stoneley (University of Cambridge) and Dr. C. J. Jaeger (Australian National University, Canberra). In addition, papers were received from M. A. Tuve and H. E. Tatel (Department of Terrestrial Magnetism, Washington, D.C.), from Prof. L. Cahen (Musée Royal du Congo Belge, Tervuren) and from the National Meteorological Service of Portugal. The papers will be published by the authors independently in various scientific journals.

Antwerp 'Zoo' Bulletins

Before the Second World War the Société Royale de Zoologie d'Anvers published a bilingual, French and Flemish, review termed *Zoo*, which was well known to visitors to the Antwerp Zoological Gardens. For financial and other reasons, this has not been restarted since the War. To some extent, it is now replaced by "Bulletins", limited to four numbers in the year, of which the first three are to hand, consisting of 24, 48 and 54 pages, respectively. They are issued by the Society under the general direction of Mr. Walter Van den bergh and the editorship of M. M. Palmans. The first number, July 1953, treats of the infection of penguins with plasmodium by Dr. J. Rodhain; the second is a description of freshwater fishes from the Belgian Congo, by Dr. Max Poll, many of which are on view in the Antwerp gardens; and the third treats of various aspects of the acclimatization of the okapi and has contributions by Dr. L. M. G. Guerden and Dr. Vendermander (Ghent), Axel Reventlow (Copenhagen) and C. S. Webb (London). They are all well illustrated by half-tone reproductions of photographs. The treatment is not fully technical but at the same time not popular, and they contain much useful information derived from actual experience. The second bulletin, that on fishes, with illustrations of thirty-four different species living in the Antwerp aquarium, shows that, apart from the scientific interest of some of them, there are a number that make attractive additions to an aquarium.

The Museums Association

The annual report of the Museums Association published in the July issue of the ***Museums Journal*** is a reminder of the growing status of these institutions and their increased usefulness to the community. For the Association, 1953–54 has been a year of exceptional activity, the beginning of a number of new ventures and marked by the continued improvement in its finances. The Handbook Panel issued its first publication and the Directory Panel is now collating the results of an extensive questionnaire. A technical certificate is now available to indicate the professional qualifications of those museum workers whose activities are in that particular field, and consideration has been given to the extension of the diploma scheme to other parts of the Commonwealth. As in previous years, the museum movement in Britain records with gratitude its great debt to the Carnegie United Kingdom Trust for its whole-hearted and liberal support.

Museum of Applied Science of Victoria: Report for 1953

In the report of the Museum of Applied Science of Victoria for the year ended June 30, 1953, it is interesting to note that the Museum intends to carry out radiocarbon (carbon-14) determinations in the near future. The few existing centres in Australia doing this work are unable to cope with all the demands, and the provision of a laboratory for this modern technique will be invaluable to Australian research workers. The acquisition of an 8-in. equatorial telescope in 1945 has resulted in a well-established and popular service to the public. With the generous assistance of a panel of honorary demonstrators from the Astronomical Society of Victoria, members of the public are able to observe the night sky.

Queen Elizabeth Forest Park

A guide to the National Forest Park, comprising Ben Lomond, Loch Ard and the Trossachs, has been compiled by Prof. John Walton, of the University of Glasgow. In commemoration of the Coronation of Her Majesty, it is fitting that this beautiful park should be named the Queen Elizabeth Forest Park. Of all the national forest parks, this is likely to be visited by the greatest number of the public; unlike the others, it is situated within easy reach of the large populations of Edinburgh, Glasgow and the industrial districts of the central valley of Scotland. Moreover, it includes part of the Trossachs, which has for many years attracted visitors in large numbers from all parts of the world.

The Forestry Commission in 1928 acquired land in the neighbourhood of Loch Ard, and with later acquisitions has brought under national ownership no less than 41,454 acres extending from Loch Venachar and the headwaters of the Forth over the summit of Ben Lomond to the shores of Loch Lomond. The area marches with the main part of the beautiful Trossachs. Plantations covering an area of more than 13,000 acres have been established, while there are nearly 20,000 acres of lochs and mountains which are available for those who find joy and recreation in exploring the wild countryside. Besides sections dealing with the geology, botany, bird and mammal life of the area, the guide contains an account of the structure and freshwater biology of Loch Lomond, Gaelic place names and their derivations, as well as an account of the Trossachs in literature. The guide also contains a useful Ordnance Survey map of the area. Guides cost 3*s*. each and can be obtained from H.M. Stationery Office.

Sea-horses in a School Laboratory

Many people regard sea-horses (*Hippocampus* sp.) as fictitious or heraldic or have heard of them only from mythological references in ancient literature. Apart from the excellent exhibit at the London Zoo, under the care of Mr. H. Vinall, and in a few seaside aquaria such as that at Plymouth, these animals are seldom seen alive in Britain. There are many laboratory difficulties in trying to maintain a stock of sea-horses; they do not acclimatize easily, refuse to eat and eventually die of starvation. Clean seawater has constantly to be procured, continuously to be aerated and maintained at a temperature of 75° F. by means of thermostatic control. The Edinburgh and East of Scotland Aquarium Society very enterprisingly showed some fine specimens at its annual exhibition in 1953 and these were later transferred to the biological department of Loretto School. Although they were never given any formal lessons on the subject, a group of fifty schoolboys were given a surprise question in an examination paper on the habits of sea-horses. Their observations have been put together in a most stimulating article by A. S. Gillespie (*School Nat. Study J.*, 49, 196; July 1954).

Protection of Plants

The thirty-fourth report of the Quebec Society for the Protection of Plants (Pub. Dept. Agriculture, Province of Quebec, May 1954; n.p.) includes, among other general matters, a number of papers presented at the annual meeting and also the papers contributed to a symposium on "Viruses and the Protection of the Plant Kingdom". These last range widely, and include studies of infection, identification, relationships of strains, the induction of mutants, host reaction, mutual adaptation in viruses and their hosts, resistance, immunization, agents of dissemination, and other topics.

Chemical and Plastic Materials Exhibition in Paris

The third Salon de la Chimie et des Matières Plastiques will be held at the Parc des Expositions, Porte de Versailles, Paris, during December 3–12. On each of the eight weekdays during this period a technical meeting will be held to discuss the following subjects: new vacuum techniques; perfumery and cosmetics; chromatography and ion exchange; applications of microscopy in chemistry; anti-fouling paints; electronic techniques in the service of chemistry; control and regulation systems in sugar refineries, and corrosion; and recent developments in plastics, and corrosion. Last year the Salon included 650 exhibitors from thirteen countries, and two hundred thousand visitors attended; this year the Salon will be even larger, and an area of just over six acres has been reserved. In all, there will be four separate but complementary exhibitions as follows: laboratory equipment (instrumentation, optical, testing, measuring, control and regulating equipment); chemical products (pure, industrial and finished products); chemical engineering (general and special plant); and plastics industry (raw materials, materials for processing, and manufactured articles). Concurrently the third session of the Chemical Engineering Conference will be held, when many of the problems encountered in the operation of modern factories will be reviewed. Further information on all these events can be obtained from the Commissariat Général, 28 rue Saint-Dominique, Paris 7°.

National Research Council of Canada: Postdoctorate Fellowships for 1954–55

The National Research Council of Canada has awarded sixty-eight postdoctorate fellowships for the year 1954–55 for research in the Council's laboratories. The fellowships, which are worth 3,000 dollars tax-free (3,500 dollars for married men), are awarded without regard to nationality to persons less than thirty-five years of age with a Ph.D. degree of a recognized university. The distribution of the awards between the various Divisions of the National Research Council is as follows: applied biology, 10; applied chemistry, 9; pure chemistry, 25; physics, 17; and radio and electrical engineering, 1. In addition, five fellowships will be held at the Prairie Regional Laboratory, Saskatoon, and one at Science Service of the Department of Agriculture.

Pesticides Group of the Society of Chemical Industry

The Society of Chemical Industry is forming a new Group—the Pesticides Group—based on the former Crop Protection Panel of the Society's Agriculture Group. The present membership of the new Group is about two hundred and forty, mainly derived from the former Panel, but with the now extended terms of reference it is hoped that the Group will be widely supported by individuals and firms with an interest in pesticides, but not necessarily in the field of agriculture. The inaugural meeting and dinner of the Group will be held on October 18. Further information can be obtained from the General Secretary, Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

Advisory Council for Scientific and Industrial Research: New Members

The Lord President of the Council has appointed Dr. E. Ashby, president and vice-chancellor of The Queen's University, Belfast, Mr. S. Barratt, finance director of Messrs. Albright and Wilson, Ltd., Oldbury, Birmingham, Prof. E. A. G. Robinson, professor of economics, University of Cambridge, and Dr. C. Sykes, managing director of Messrs. Thomas Firth and John Brown, Ltd., Sheffield, to be members of the Advisory Council for Scientific and Industrial Research in succession to Prof. R. S. Edwards, Lord Halsbury, Sir Henry Hinchliffe and Mr. A. H. Wilson, who retire from the Council on September 30. Sir Hugh Beaver is to succeed Sir Ian Heilbron as chairman of the Advisory Council on October 1. The other present members of the Council who continue to serve after September 30 are: Sir Wallace Akers, J. Crawford, Prof. T. R. C. Fox, W. L. Heywood, Sir Philip Johnson, Sir Eric Rideal, Sir George Thomson and Sir Ben Lockspeiser (secretary).

Announcements

A course of twelve lectures and demonstrations on the theory of photoelasticity and the practical application of photoelastic methods to the investigation of two-dimensional stress distributions will be given in the Faculty of Engineering, University College, London, on successive Mondays (2–3 p.m.), commencing on October 11. A course of twelve lectures and demonstrations on recent developments in the photoelastic investigation of three-dimensional stress problems will similarly be given on Mondays, commencing January 31, 1955. The fee for each course is 7½ guineas, or 14 guineas for both (free to students of University College). Further information can be obtained from the Secretary of the College, Gower Street, London, W.C.1.

The Bone and Tooth Society will hold a symposium on "Vitamin D and Bone" on September 30 at the Institute of Orthopaedics, 234 Great Portland Street, London, W.1, at 5 p.m. Sir Edward Mellanby will speak on "Vitamin D and Nutrition" and Dr. E. Kodicek on "Balance Studies of Vitamin D in the Rat". There will also be a joint contribution from Dr. J. Anderson, Dr. C. E. Dent and Dr. B. Senior on "Vitamin D and Phosphate Excretion". Further information can be obtained from the Secretary, Bone and Tooth Society, Biochemistry Department, Institute of Orthopaedics, Royal National Orthopaedic Hospital, Brockley Hill, Stanmore, Middlesex.

SIXTH COMMONWEALTH ENTOMOLOGICAL CONFERENCE

AT the Sixth Commonwealth Entomological Conference, held in London during July 7–16, there were fifty-five delegates, a greater number than ever before, and these included representatives from nearly all the countries of the British Commonwealth. The open meetings attracted a large attendance of entomologists from Britain and overseas, and a wide field of subjects was discussed.

The principal advances in economic entomology continue to be in the development and application of synthetic insecticides and in the study of problems arising from their use. Dr. H. G. H. Kearns (University of Bristol Fruit Research Station) reviewed the synthetic insecticides used on field crops and the methods of applying them. It is more difficult to treat field crops than plantation or orchard crops, and the margin of profit limits what can be done. These considerations apply particularly to peasant-grown crops, for which dusting, though an inefficient way of using toxic materials, has the advantage of requiring no water and of permitting the use of simple equipment.

The application of insecticides from aircraft was dealt with first by Mr. D. Yeo (Colonial Insecticides Research Unit, Tanganyika), with particular reference to tsetse fly. Methods using residual deposits are not economic against species spread through savannah woodland; but in large-scale experiments using 'space sprays' that deposit toxic droplets directly on the fly kills approaching 100 per cent have been reached. The behaviour of droplets of such a size (about 50 μ) that they neither impact on the canopy nor fail to settle is greatly affected by atmospheric turbulence: application is thus restricted to brief periods around dawn and dusk, when conditions are still, and this renders the use of aircraft uneconomic. Dr. R. C. Rainey (Desert Locust Survey) discussed developments in spraying flying locust swarms from aircraft. Methods of graphical analysis of the factors involved, together with laboratory indications that locusts are far more susceptible to insecticide when flying than when resting, have provided the background to aerial attacks on swarms recently invading East Africa. By bringing together data from many sources, estimates of efficiencies and costs have been obtained which suggest that the method is not seriously more expensive than hopper-baiting, to which it is complementary, making it possible to attack locusts throughout their life-cycle.

Dr. A. M. Massee (East Malling Research Station) illustrated the effect of insecticides on the balance of animal populations by the history of certain orchard pests. The mite *Metatetranychus ulmi* became a serious pest after the adoption of tar–oil washes, which are non-toxic to its winter eggs but killed many of its predators that hibernate on the tree, and the use of DDT and organo-phosphorus compounds made matters worse. DDT also favours woolly aphis, *Eriosoma lanigerum*, by destroying its parasite, *Aphelinus mali*; on the other hand, it has virtually eliminated the apple capsid, *Plesiocoris rugicollis*, which had become an important pest under the previous spray programme. Spider mites can now be controlled by summer ovicides that are relatively harmless to beneficial insects and mites; this advance underlines the need for more selective rather than more toxic insecticides.

In opening the discussion on the development of resistance to insecticides, Dr. J. R. Busvine (London School of Hygiene and Tropical Medicine) said that authentic cases, among which pests of medical importance preponderate, are mostly of recent occurrence, and it is not clear whether this results from a more widespread use of insecticides or from the way the modern ones act. The possibility and speed of development of resistance depend on the frequency of occurrence and effectiveness of resistant genes in the original population, the intensity of selection and the rate of reproduction. Little is known of the mode of action of resistance: one mechanism appears to be the conversion of toxic to innocuous compounds; but another one, differently inherited, is required to explain resistance to 'knock down'.

Dr. I. Thomas (Plant Pathology Laboratory, Harpenden) opened the discussion on the estimation of losses from pests by referring to early work based on mechanical simulation of damage, and then outlined the methods used in Britain by the National Agricultural Advisory Service, under the guidance of the Pest Assessment Committee. He emphasized that pest damage is only one of several factors affecting crop yields and that, especially in under-developed countries, it may not be the limiting one. His colleague, Mr. A. H. Strickland, described in more detail the use of insecticides to obtain differences in pest density on experimental plots. Regressions of yield on infestation thus obtained for each district can be integrated with rapid district-wide assessments of infestation to provide valid estimates or even forecasts of yield losses. A subsidiary development is the collation of pest densities with ecological features, thus enabling situations associated with high infestations to be defined and avoided. Mr. Q. A. Geering (Cotton Research Station, Uganda) described a method used in Uganda for studying losses caused by cotton mirids. This utilizes single-row plots from which the pest is repelled by an insecticide, and is valuable in the case of mobile insects, for which ordinary plot methods break down. The results show how a plant which flowers over a considerable period can ultimately compensate for severe early damage, the real loss being in time rather than in yield.

Dr. W. R. Thompson (director of the Commonwealth Institute of Biological Control) outlined recent attempts to control two scale insects accidentally imported into Bermuda that have attacked the dominant shade tree there, a species of cedar that is unique to the island and, perhaps for that reason, highly susceptible to scale attack. Although some one and a half million individuals of forty species predatory or parasitic on scales were introduced, only two species, both Coccinellids, have become established. It appears that predators, as well as parasites, may have highly specific host-relationships. The Coccinellids now show signs of holding scale infestations below a level lethal to the surviving trees; but the lack of more striking success in a biological control operation on an island is surprising and emphasizes the need for further research if the results of such experiments are to be understood.

The principles underlying the biological control of weeds were discussed by Mr. J. R. Williams in a paper read by Dr. R. Mamet, both of the Department of Agriculture, Mauritius, where spectacular control of the introduced weed *Cordia macrostachya* has been effected by the leaf beetle, *Schematiza cordiae*. Essentially they involve exhaustive tests to show that the insect introduced is restricted to the weed to be controlled; the danger of the evolution of strains adapted to other, desirable plants after the elimination of the undesirable one seems slight, because the period during which intense selection of such strains would operate, following the rapid collapse of the weed population, would perforce be short.

In the discussion on pests of tropical cereal crops, both the opening speakers stressed the need for special research, and the Conference endorsed this view. Dr. H. F. Barnes (Rothamsted Experimental Station) reviewed recently acquired records of the occurrence of certain important grain midges, and pointed out that the existence of biological races necessitates experimentation to show whether sorghum midge, which is a particularly serious pest, is a single species being spread with seed or a complex of species that have arisen independently by convergent evolution. Mr. J. Bowden (Department of Agriculture, Gold Coast) said that damage by stem-borers had been insufficiently appreciated and investigated because of the preoccupation of entomologists with cash crops. The two needs are critical taxonomic and biological studies of the groups concerned, and standardized ways of assessing infestation and damage; the methods developed in the Gold Coast, though simple, seem adequate.

Mr. G. V. B. Herford (director of the Pest Infestation Laboratory) spoke of the increasing realization of the magnitude of problems of stored-product pests, particularly those of the Colonial territories, where a number of research and advisory units, with which close liaison is being maintained, are now engaged. Notable technical developments include the extended use of the fumigation of bagged produce under gas-proof sheets, and greater provision for bulk storage of grain, either in silos utilizing circulatory fumigation or in sealed underground pits.

Dr. R. C. Fisher (Forest Products Research Laboratory, Princes Risborough) began the discussion on problems of forest entomology, and referred to another example of the establishment in a tropical region of a unit linked with a research institute in Britain, namely, the team studying bark beetles in West Africa. In this investigation and in those carried out at the Forest Products Research Laboratory, the emphasis is on the study of the biology of the insect and the relation of its attack to the history and condition of its host timber. Dr. F. T. Bird (Division of Forest Biology, Canada) gave an account of the use of virus diseases of European origin against two introduced sawflies. The virus, which has maintained an extreme virulence, has been artificially disseminated and gives rise to epizootics in succeeding years, being transmitted from year to year via the egg. The mortality is dependent on the population density and habits of the sawflies, and at low densities is greater in the spruce sawfly, the eggs of which are laid singly and whose larvæ feed singly.

Mr. W. V. Harris, who opened the discussion on termites, outlined the programme and progress of the Colonial Office Termite Research Unit, of which he is in charge. He mentioned some interesting points that have already emerged from the rapidly accumulating data on termite distribution and ecology in East Africa, and directed attention to the dispersal of injurious dry-wood species that is taking place around the tropics.

Mr. L. G. Putnam (Division of Entomology, Canada), in a paper read by Mr. A. B. Baird, discussed developments in grasshopper research and control in Canada. Grasshoppers, unlike locusts, are not strictly gregarious, and do not normally undertake long flights. Outbreak centres thus do not exist: overall abundance appears to depend on weather factors, now being analysed, and as the insects are univoltine and lay their eggs, which overwinter, in or adjacent to stubble, the intensity of damage is determined by the degree of juxtaposition of successive crops. Dr. B. P. Uvarov (director of the Anti-Locust Research Centre) dealt with the more complex dynamics of locust plagues, involving not only fluctuations in numbers but also changes in the extent of the populated area and qualitative differences between solitary and swarming populations. Quantitative studies of numerical fluctuations and of their causes, especially biological ones, are now being pressed forward. A connexion has been demonstrated between large-scale swarm-displacements and movements of air masses, and the more mysterious movements that solitary adults are known to make are being studied. Recent work suggests that gregarious behaviour arises from conditioning, and persists even though the conditioning factors no longer operate.

Dr. C. H. N. Jackson (Tsetse Research Laboratory, Tanganyika) discussed the principal methods that have been used for controlling tsetse. These mostly depend on the selective destruction of some essential feature of the fly's environment, such as the vegetation characterizing the favoured breeding site or affording protection against desiccation, or the animals that constitute the food supply or a principal element in it. Insecticides are effective, though rather expensive; their use leaves the environment unaltered and discloses the interesting likelihood that fly populations are unable to recover after reduction below a certain level. Some results of the empirical control methods have been explained by research on tsetse physiology and behaviour, but much more of such work is needed.

Dr. W. J. Hall (director of the Commonwealth Institute of Entomology), in opening a discussion on the supply and training of taxonomists, said that the existing provisions for taxonomic research and for the identification of insects and mites of economic importance are inadequate. Substantial increases in staff are needed in organizations connected with these activities, which are interdependent. A number of other suggestions for improving the situation were discussed, and a committee was set up to make recommendations.

A full report of the proceedings, including the resolutions adopted by the Conference, will be published later in the year by the Commonwealth Institute of Entomology, together with reviews of the progress of economic entomology in the Commonwealth countries since 1948.

During the Conference, delegates visited Rothamsted Experimental Station, the Silwood Park Field Station of the Imperial College of Science and Technology, London, and the Pest Infestation Laboratory of the Department of Scientific and Industrial Research. These visits, together with certain social occasions, provided the opportunity for informal discussion between entomologists from many widely separated countries that is so valuable a feature of these Conferences.

COMPARATIVE ENDOCRINOLOGY OF VERTEBRATES

An international symposium on the comparative endocrinology of vertebrates was held in the Zoology Department, University of Liverpool, during July 12–16. It was made possible by the generous financial support of the Rockefeller Foundation and the United States National Science Foundation. The Derby professor of zoology, Prof. R. J. Pumphrey, on behalf of the University, officially welcomed the participants, who numbered about seventy-five. The symposium was divided into two parts, the first entitled "The Comparative Physiology of Reproduction" being under the chairmanship of Prof. S. Zuckerman; for the second part, on "The Hormonal Control of Water and Salt-electrolyte Metabolism in Vertebrates", Dr. S. J. Folley took the chair.

The first two days were devoted to a comparative survey of reproduction, starting with a paper on fish by Prof. W. S. Hoar (Vancouver), who, even though confining his survey to the teleosts, surprised many of his audience with the wide variety of reproductive patterns ranging from oviparity to viviparity met with in the bony fish. In discussion of this paper, Dr. A. S. Parkes raised the interesting question of how the sperm penetrates into the ovarian follicles in those forms in which intrafollicular fertilization occurs. This question could not be answered.

Prof. G. J. van Oordt (Utrecht) dealt with the male amphibian, his paper describing an experimental analysis of seasonal fluctuations in spermatogenesis in frogs which emphasized the part played by variations in sensitivity of the seminiferous tubules to pituitary gonadotrophins. In the discussion, Dr. H. Tuchman-Duplessis referred to experiments on the newt which suggested that cyclic variations in pituitary gonadotrophic activity may be another factor involved in seasonal changes in spermatogenesis in amphibia. Dr. C. L. Smith (Liverpool) in surveying reproduction in female amphibia discussed the role of exteroceptive factors such as rainfall and temperature in controlling pituitary activity via the hypothalamus. He described experiments on the relation between thyroid activity and the sympathetic system which might bear upon the possible participation of an adrenergic component in the functional pathway between the hypothalamus and the hypophysis.

Reptiles, which have been comparatively little studied by endocrinologists, were surveyed under four heads, Sauria, Ophidia, Crocodilia and Chelonia, by Dr. R. Kehl (Algiers) in a joint paper with C. Combescot. Much of the paper was taken up with a description of Dr. Kehl's own work on the Algerian saurians, *Uromastix* and *Acanthodactylus*, which is providing much needed additional information about this class. Dr. M. R. Miller (California), in the discussion, described Californian reptiles in which the male interstitial cells show no evidence of endocrine activity. The meeting entered upon less exotic ground with a stimulating survey by Dr. A. J. Marshall (London) of reproduction in male birds, which included some slides illustrating his own observations on the periodic appearance of cholesterol-positive lipids in the testes. His references to the work of K. G. Wingstrand and particularly that of J. Benoit and I. Assenmacher, which suggests that the gonadotrophic function of the pituitary in birds is stimulated by a chemotransmitter of neurosecretory origin passing down the pituitary portal vessels, followed by an all-too-brief exposition by Prof. Benoit himself of his elegant experiments, aroused much interest. This prompted Prof. Zuckerman, who earlier as chairman had eschewed controversy by virtue of his office, to express scepticism as to the completeness of the experimental evidence for the involvement of the pituitary portal vessels in the hypothalamic control of pituitary function as postulated by Benoit for birds and by G. W. Harris for mammals. Reproduction in female birds was surveyed by Dr. W. R. Breneman (Indiana), who, in the course of his exposition, described cytological work carried out by his colleague, F. Payne, on the avian pituitary in various reproductive phases. Evidence that the avian ovary produces progesterone and androgen as well as œstrogen was presented. This paper gave rise to discussion on, among other topics, the mechanism which determines the number of eggs in a clutch. This is probably neurogenic, and it seems possible that it may be more or less analogous to the suckling stimulus in mammals which, if intense enough, can stop the ovarian cycles. This theory involves the idea that the brood spots of birds are homologous with the mammæ of mammals and so may be sensitive to prolactin, as may be the ventral glands in the Chinese swifts said to secrete the edible birds' nest cement, prized by gourmets as an ingredient of soup.

Prof. Zuckerman at this point exchanged the role of chairman for that of lecturer and, with characteristic scholarship, surveyed the mammals in a joint paper with P. Eckstein. His main thesis in reviewing the manifold reproductive patterns found in this class was that many of these variations may not be differences in kind so much as components of a continuous spectrum. In discussing this paper, Dr. S. J. Folley cited the domestic cow as a probable example of a form from which a primitive breeding season has been eliminated by selective breeding. This was followed by diverting exchanges between Prof. Zuckerman and Dr. Parkes, who pleaded for the simple view of natural phenomena. Dr. L. Harrison Matthews (London) then undertook a wide survey of reproductive processes in vertebrates in a paper the topic of which was the evolution of viviparity. The discussion on this paper was notable for an impressive and scholarly contribution by Prof. E. C. Amoroso in which, after considering the adaptations which viviparity has necessitated, he drew a penetrating parallel between the increasing complexity of the endocrine function of the placenta and the lengthening of pregnancy. The comparative survey was concluded by a paper by Dr. E. Witschi (Iowa) on vertebrate gonadotrophins which was mainly occupied by a consideration of results obtained with an assay technique based on plumage changes in the weaver finch. He concluded from his results that the luteinizing and interstitial-cell-stimulating hormones are separate and distinct pituitary hormones, a conclusion which, however, did not command the support of two of his compatriots, Drs. R. O. Greep and J. H. Leathem.

The third day of the symposium was occupied by papers on the effects of sex hormones in vertebrates. Dr. J. M. Dodd (St. Andrews) began with a survey of the position in fish and lower chordates, in the course of which it became evident that his results lead him to differ somewhat from the views of D. B. Carlisle on the endocrine function of the sub-neural gland in ascidians which some regard as a primitive pituitary. Dr. Carlisle intervened in the discussion to clarify his position. Dr. L. Gallien (Paris) described experiments on the effects of sex hormones on sexual differentiation of the larvæ of amphibia. It is possible to achieve total sex inversion in amphibians by administration of the appropriate (mammalian) sex hormone at an early enough stage, showing that the development of the gonocytes is controlled not by genes but by endocrine factors arising out of the competing influences of the gonadal cortex and medulla. Dr. R. M. Fraps (Beltsville), in dealing with birds, described interesting experiments on the mechanism of ovulation in the domestic hen which indicate that the secretion of ovulating gonadotrophin (LH) by the pituitary is called forth by a progestogen (progesterone itself ?) secreted by the follicle next due to ovulate. The secretion of the progestational hormone is probably evoked by pituitary luteotrophin (prolactin). In the discussion on this paper Prof. Benoit described among other things the masculinizing effect of cortisone on ducks.

Dr. J. H. Leathem (Rutgers), to whom the paper on mammals was entrusted, discussed important species differences in the effects of steroids on the reproductive system of both male and female. Dr. T. Mann, commenting on this paper, illustrated this point by references to the marked differences between various species of mammal as regards the respective sites of origin of the fructose and citric acid found in the seminal plasma. Dr. A. Jost (Paris) concluded this part of the symposium with a paper describing his investigations on the effects of sex hormones on sexual differentiation in the fœtus, which show that this is not a continuous process ; rather, there occurs a critical period of testicular activity during which the character of the sexual structures is determined for life. Experiments involving hypophysectomy by the rather drastic procedure of decapitation (which, incidentally, is not fatal to the fœtus) indicate a gonadotrophic function for the fœtal pituitary. His admiration for the elegance of Dr. Jost's experiments tempted the chairman into a gentle tilt against the chemists, who, however, found a champion in Dr. Folley. In a masterly summing-up of this part of the proceedings, Prof. Zuckerman referred to the unique character of the meeting thus far, so broad and all-embracing had been the field covered. He reminded his audience that despite the astonishing variety of the reproductive patterns encountered even within one class, the underlying mechanisms seem nevertheless basically the same all through. It was good to hear Prof. Zuckerman predict that endocrinology will soon emerge from the "ACTH–cortisone era".

In opening the second part of the symposium, the chairman, Dr. Folley, referred to the evolution of devices for conserving water so as to preserve the aquatic environment necessary for the aqueous cell chemistry which is the basis of life. In considering the role of the endocrine system he mentioned recent achievements such as the discovery of aldosterone and the synthesis of the oxytocic polypeptide which can only serve to encourage further efforts in this field. The first paper, given by Prof. E. J. Conway (Dublin), began with a fundamental treatment of ionic equilibria in isolated muscle tissue before proceeding to consider the application of these principles in studies involving the adrenal cortex. It was interesting to learn that adrenal corticoids can influence ionic transport through the cell membrane of the yeast cell. Prof. H. Heller (Bristol) in a paper on mammals described the various physiological stimuli (dehydration, stimulation of vagal afferents, suckling, etc.) which cause secretion of the pressor-antidiuretic hormone. An old adage of the Hogben school, to the effect that when one measures hormone excretion in the urine one may be merely studying kidney physiology, came to mind in connexion with the mention of findings which suggest that the kidney may convert pressor-antidiuretic hormone into a less biologically active form prior to excretion. In comment upon a point raised by Prof. Heller's paper, Dr. Folley referred to the careful experiments of Mrs. M. H. I. Dodd at Shinfield which indicate that neither the lactating state itself nor the application of the milking stimulus has any detectable effect on the amounts of pressor-antidiuretic hormone and oxytocin in the posterior lobe of the goat. He also pointed out that evidence of differential secretion of the two posterior lobe principles has been provided by the work of G. Peeters, of Ghent, who showed that suckling antidiuresis in water-loaded cows could be inhibited by mild fright, while the milk-ejection reflex (believed to involve oxytocin secretion) was not affected. An interesting contribution to the discussion came from Dr. F. G. Hofmann, who described a creature of the American desert, the kangaroo rat, which is geared to maximum water conservation and shows a great impediment to water excretion, yet its response to pressor-antidiuretic hormone is equal to that of the ordinary rat.

A paper on amphibia was read by Dr. W. H. Sawyer (New York). He emphasized the key position of this class which, situated as it is between water and dry land, may provide the best experimental medium for elucidating the basic principles of salt and water balance. Dr. Sawyer visualized the neurohypophysis as playing the primary part in regulating water balance and the adrenals as having precedence in regulating salt metabolism. He felt that, for amphibia as for mammals, the respective roles of the two glands are complementary rather than antagonistic as so often regarded. In the ensuing discussion, Dr. C. Barker Jørgensen described experiments, partly with K. G. Wingstrand, on section of the supraopticohypophysial tract in *Rana temporaria* which resulted in a decrease of neurosecretory material but did not affect the rate of water uptake. Then Dr. V. Capraro (Milan) read a joint paper with M. L. Garampi describing experiments on effects of posterior-pituitary extracts on the rate of water flow through the isolated frog skin which indicate that mechanisms more complicated than simple changes in pore size are involved. As pointed out by Prof. Pumphrey, such results are likely to depend to an important degree on the season in which the frogs are taken, since the winter frog is physiologically a very different creature from the summer frog.

In the final session the first paper was by Prof. M. Fontaine (Paris), who gave an excellent general survey of the endocrine control of water and salt metabolism in fish. He was followed by Dr. D. C. W. Smith (St. Andrews) with an admirable account of some of the interesting work in progress at the Gatty Marine Laboratory on the relation between the endocrines and salinity tolerance in Salmonidæ. The thyroid hormone and pituitary somatotrophin seem to be of importance here. The last paper was given by Dr. I. Chester Jones (Liverpool), who in refreshing style surveyed the role of the adrenal cortex in salt and water metabolism in vertebrates. In the discussion, observations on water diuresis in patients with adrenal insufficiency were described by Dr. A. Slessor, while Dr. M. Ginsburg described experiments on the relation between the adrenals and the rate of disappearance of injected pressor-antidiuretic hormone from the blood in rats.

In the course of both parts of the symposium there were references from time to time to a dictum attributed to a distinguished zoologist not present at the meeting, to the effect that it is not the hormones themselves which evolve but rather the uses to which they are put. The chairman briefly returned to this concept in his final summing-up. He regarded it as inherently improbable and cited a number of facts which suggest that hormones are suitable material upon which the evolutionary process can work. This prompts the thought that if a sequel to this symposium is organized in a few years time—and in view of the evident success of the present one it is to be hoped that this will be the case—then perhaps a suitable theme will be "The Evolution of the Endocrine System".

If the above suggestion is acted upon, it would please many if the sequel were held under the same auspices, for the atmosphere of this symposium was extraordinarily pleasant and all the arrangements reflected great credit upon the originator and organizer, Dr. I. Chester Jones. This was acknowledged in a graceful speech at the end by Prof. Benoit, as was the pleasant hospitality accorded to the participants in functions arranged by the Merseyside Civic Society, the University of Liverpool and Prof. Pumphrey.

By arrangement with the Society for Endocrinology, the proceedings will be published as soon as possible in two volumes (Nos. 4 and 5) of the recently established series of *Memoirs* of that Society, the Royal Society having made a generous grant towards the expenses of publication.

S. J. FOLLEY

PHYSIOLOGY IN HUNGARY

THE twentieth (anniversary) annual conference of the Hungarian Physiological Society was held during July 8–10 in Budapest, under the presidency of Prof. Brunó Straub, and to mark the occasion the Hungarian National Academy of Sciences invited a number of guests from other countries to attend the meetings and to participate in the discussions. The programme, which contained 128 communications, demonstrated both the high quality of work in progress in the fields of physiology, biochemistry and pharmacology, and also the remarkable number and keenness of the younger generation of Hungarian scientific workers. Besides these papers, which were divided into three concurrent sections, there were plenary sessions, the first being devoted to a general report by Prof. G. Romhányi (University of Pécs) on the most recent discoveries relating to biological structure and function, and the others to lectures and communications by the foreign visitors.

From neighbouring countries came, among others, the Polish biochemists and physiologists, W. Niemerko (now director of the Nencki Institute, soon to return from Lódz to new quarters in Warsaw) and W. Missiuro; several Czechoslovak guests, including Dr. E. Gutmann (who at one time worked in Oxford); the Rumanian medical physiologists, Danielopulo and Julius Nitzulescu; and Prof. Gotséeff, of Bulgaria (one of the pupils of the late Sir Joseph Barcroft). The U.S.S.R. sent Prof. P. S. Kupalov (a former colleague in years gone by of Prof. A. V. Hill), Prof. S. C. Koschtojanz, the comparative physiologist, with the neurologists R. Kavetsky and A. Vorobyov. From the United Kingdom came the present writers, and from Germany the biophysicist Prof. Havermann (Berlin).

For more than twenty-five years, especially since the fundamental work of Szent-Gyorgyi and Straub in 1941 on the relations of actin and myosin, Hungarian physiology and biochemistry have been renowned for interest in the mechanism of muscular contraction. This was particularly in evidence at the present meetings, and for reasons of personal interest we shall report upon it a little more fully. Subjects which came under lively discussion included the effects of various extractants upon the appearance of muscle fibrils under the polarizing and electron microscopes; the early rapid phase of volume diminution accompanying the action current; the binding of metallic ions (especially Ca^{++} and Mg^{++}) by actin and myosin; and comparison of these proteins with others in this respect. The binding of Ca^{++} by muscle mitochondria was also reported upon. Interesting discussions were evoked by new investigations of the bound nucleotides in muscle and other cells, not only by Hungarian workers but also by Niemerko from Poland. A further topic was the cholinesterase activity of the mero-myosins prepared by tryptic hydrolysis; all of it was found to be in the L-mero-myosin just as all the adenosine triphosphatase activity is in the H-meromyosin. Among the workers presenting these papers were, with their many collaborators, E. Ernst, F. Guba, T. Erdős, G. Feuer, E. Biró, M. Bárányi and E. Varga.

Dr. I. Banga described some recent developments of her work on elastin, particularly in relation to the dependence of its elasticity on provision of water. Since elastin itself cannot bind water, the presence in the neighbourhood of water-binding collagen is essential. Dr. Banga and her husband, Prof. Joseph Baló, who directs one of the institutes of pathology in the University of Budapest, are much concerned with problems such as those of arterio-sclerosis.

Prof. Straub, while maintaining his interest in actin, has turned his attention also to protein synthesis. Papers from his laboratory included those on penicillinase synthesis in *B. cereus*, and on amylase synthesis in pancreas homogenates, in the presence of adenosine triphosphate. Interesting effects of ions on glutamine synthesis were also reported.

At the conclusion of the conference, the foreign visitors, together with some of their Magyar hosts, made excursions to the provinces to see the Freshwater Biological Institute on the shores of Lake Balaton, and the Universities of Pécs and Debrecen. The Biological Station at Tihány, where in the past several British investigators have worked, is in good condition, and in many ways well equipped, especially with a fine library. Under the direction of Dr. Bela Entz and Mr. I. Konok, work is proceeding on the hydrobiology of the lake with reference to the fisheries, and on the comparative physiology of invertebrates, including insect hormones. There is space for about twenty workers, and the collecting facilities include a good motor-cruiser.

The University of Pécs was first founded in A.D. 1367; but ceased to exist when the great majority of its students were killed in resisting the advance of the Turks—it was not re-founded until the present century. The town lies all on the slopes of a pleasant range of hills, and still has two mosques and a minaret among its architectural remains. The University consists primarily of the Faculties of Medicine and Law. Scientifically, it occupies a special position, as nearly all its professors are Academicians, and the National Academy of Sciences takes a particular interest in its progress. In the Department of Physiology, headed by Prof. E. Ernst, visitors were able to see ingenious apparatus for measurement of rapid volume changes using a piezo-electric quartz membrane, and micro-calorimeters for recording heat-production of muscles without contact between the tissue and the thermo-couples. One of the chairs of pathology is held by Prof. C. Donhoffer (a pupil of the late J. J. R. McLeod at Aberdeen); under his leadership interesting work in nutritional science is proceeding, especially on the effects of many different factors on the selection and intake of food by the rat. In the Department of Neuro-physiology (Prof. K. Lissák) much work on conditioned reflexes is under way; this was naturally of great interest to the Russian and Polish specialists. The Institute of Anatomy and Embryology, under Prof. J. Szent-Agothay, was also full of activity, mainly on three lines: neuro-hormonal correlations studied by lesions of the central nervous system; a new approach to 'neuro-taxis' in the study of the means whereby outgrowing axons find their way to their presumptive connexions in ganglia or central nervous system; and developmental neuro-anatomy. Here Dr. G. Székely has obtained results of much interest by homoplastic heterotopic eye transplantations in the newt, giving reversed reflex reactions to prey after innervation. Learning to overcome this is possible with half an eye but never with a whole one. Lastly, in the Department of Histopathology (Prof. G. Romhányi) work is well advanced on the study of artificial birefringent fibrils of polymerized deoxyribonucleic acid.

Throughout the conference, Magyar hospitality was at its most charming, and the visitors carried away a deep impression of the vitality of Hungarian physiology and biochemistry.

CROSSED LAMELLAR STRUCTURE IN HIGHER PLANTS

A. B. WARDROP has directed attention to the existence of crossed lamellar structures in the cell walls of higher plants, such structures having hitherto been known with certainty to occur in some green algæ (*Australian J. Bot.*, **2**, 2, 154; 1954). When a number of higher plants in which it was considered that this structure might be present were examined, it was demonstrated in the phloem fibres of *Vinca major* and the tracheidal elements of the aerial root of *Alstonia spathulata*. In the latter, two types of crossed structure are recognized: in one, bands of laterally associated micro-fibrils c. 0·5 μ wide intersect at variable angles, whereas, in the other, lateral association is complete, forming a crossed lamellar structure which approaches most nearly that occurring in the algæ. In the outer layer of the secondary wall of wood fibres of *Eucalyptus elaeophora* and *E. regnans* there is inconclusive evidence of a crossed structure similar to that observed in the cell walls of some vessels, which consists of a loosely formed meshwork of aggregates of microfibrils. This structure is considered to be distinct from the crossed lamellar and cross-banded structures. The paper is illustrated by a number of electron micrographs.

The same author has also reported on the mechanism of the surface growth involved in the differentiation of fibres and tracheids (*ibid.*, p. 165). An electron microscopic investigation was made of the differentiating xylem elements of *Pinus radiata*, *Eucalyptus elaeophora* and *Ulmus* sp. In the tips of fibres and tracheids there is a tendency for the microfibrils of cellulose to be oriented in the direction of growth. It is considered that this orientation can be disturbed by subsequent dimensional changes in the cell. The thin areas of the differentiating cells which are involved in the so-called 'mosaic growth' have been compared with the regions of the cell wall penetrated by plasmodesmata in the storage parenchyma of potato tubers. The suggestion is made that the thin areas are regions of the cell wall penetrated by plasmodesmata, or are developing primary pit fields. The implications of this concept, with respect to intercellular readjustment and to the differences between fibres and tracheids in extension growth, are discussed.

FORESTRY IN JAMAICA

ANNUAL REPORT FOR 1952–53

IN the annual report of the Forest Department of Jamaica for the year ending March 1953*, allusion is made to the devastation caused by the great hurricane of 1951 and the rehabilitation work, forestry and planting carried out in 1952. Jamaica's forest policy is outlined in the report as follows: protection and development of the Island's natural forest resources, that is, existing forest reserves and future extension thereof; afforestation of suitable accessible areas with the view of increasing timber production and eventually making the Island self-supporting; encouragement of afforestation and sound forest management on private lands; and research work on sylvicultural and utilization problems.

It is obvious that considerable progress has been made by the Department, as a working plan for the production reserves has been drawn up and is being worked. It provides for three working circles—plantation, improvement and natural forest. The provisions are very similar to the earlier type of working plans drawn up in India and Burma during the latter part of the nineteenth century. However, there is a serious trouble, one which was also experienced in parts of India during the early days of the Department there. The general position regarding forest reserve boundaries, says the Conservator of Forests, continues to deteriorate and is directly attributable to land hunger of an ever-increasing population. Villagers deliberately remove the boundary stones and, when prosecuted, challenge the accuracy of the original survey, thus requiring a new survey to be made. The policy of the Department is naturally to give up any suitable land for agriculture, but such sites are now unfortunately very few and far between.

---

* Forest Department, Kingston, Jamaica, B.W.I. Annual Report for the Year ended 31st March, 1953. Pp. 12. (Kingston, Jamaica: Forest Department, 1953.)

Artificial regeneration has been making considerable strides. The most popular species is mahoe (*Hibiscus elatus*); but the use of *Pinus patula* and *Eucalyptus saligna* has again been partly increased and formed approximately one-third of the area of 620 acres planted during the year. The total area of plantations formed by the Department amounts to 6,348 acres. The general planting programme has now a fairly constant pattern: above 3,000 ft. *Pinus patula* is planted on the grassland areas and *Eucalyptus saligna* on the old cultivation areas; in the middle-elevation areas, mahoe and broadleaf (*Terminalia latifolia*) are put on the sites of better soil and *Eucalyptus* species, *Pinus patula* and *Grevillea robusta* on the impoverished sites; in the coastal region mahoe is used in the drier localities and teak on alluvial flats.

INDUSTRIAL RESEARCH ASSOCIATIONS IN GREAT BRITAIN

ADDRESSING a meeting of the Parliamentary and Scientific Committee on July 13, Mr. G. L. Bailey, immediate past chairman of the Committee of Directors of Research Associations, said that the total income of the forty-one research associations in Britain to-day amounts to about £4·5 million, of which about £3 million comes from industry. The general object of the research associations is to encourage the use of scientific knowledge by industry, including both the acquisition of scientific knowledge and its application. More money is spent on research than on its application, and in his address Mr. Bailey concerned himself mainly with what is done to secure the application of research results in industry, although he instanced the work by Dr. A. J. P. Martin and Dr. R. L. M. Synge on partition chromatography and the new anti-corrosive composition formulated by the British Iron and Steel Research Association as outstanding examples of important achievements in pure research that are to the credit of a research association; the former arose out of a search for methods of analysis suitable for elucidating the chemical composition of wool, and the latter from a long-range detailed study of the corrosion of steel and its prevention.

Much of the research programme of the associations, said Mr. Bailey, is concerned with the development of new materials for a particular purpose or of new processes, and there are also smaller investigations and those relating to methods of testing or evaluation. Apart from the issue of reports or of scientific papers, the associations usually spend 15–20 per cent of their liaison service income on consultations originating in a direct approach from a member firm or arising out of a visit by a liaison officer for a general discussion. Such liaison work, moreover, is now tending to intensify application work at the expense of long-range research generally.

Dr. S. Whitehead, the chairman of the Committee of Directors of Research Associations, who followed Mr. Bailey, referred first to co-operation with universities and technical colleges, to which institutions the research associations make grants amounting to about £80,000 annually, their policy being usually to seek to interest universities in the inadequately explored portions of fundamental science on which industries are based. The research associations also bear much of the responsibility for scientific representation of their industries abroad, and government departments make great use of them on specialized projects. Mostly Dr. Whitehead's address was concerned with the question of development. Apart from their success in persuading individual members to undertake development, the research associations have sought to foster the group method of sharing the cost of development. During and since the Second World War the Government has successfully used the method of research or development contracts, and research associations have also found the National Research Development Corporation very helpful. The Coal Utilization and the Electrical Research Associations and the Shirley Institute, however, have also formed development companies, and this has two main advantages: the negotiation of commercial agreements and the technical problems of commercial application require a different type of staff and management; and, apart from some convenience over taxation, the development company hopes to make profits, and its finances can be more easily kept separate from that of its non-profit-making parent. Shirley Developments, Ltd., is concentrating at first on the commercial development and exploitation of instruments, devices and machines developed at the Shirley Institute, whereas Electrical Research Association Patents, Ltd., has largely confined itself to the granting of licences on important patents. Dr. Whitehead claimed that the research associations are at least as good as the best industrial research departments in the number of projects exploited, and that they are actively pursuing all the methods by which scientific discovery can be most rapidly, generally and fruitfully applied.

At the meeting, Sir Reginald Rootes limited his remarks to research in the motor industry, on the basis of which he maintained that the Motor Industry Research Association has fostered co-operation and done much to enable the British industry to keep abreast of its competitors; it provides buildings, research equipment and facilities on its proving-ground that are more comprehensive than those which individual manufacturers could afford. He also stressed the importance of adequate financial reserves and of research associations being able to plan their work for some years ahead.

SUB-GRAIN BOUNDARY CORROSION IN HIGH-PURITY ALUMINIUM

By M. METZGER

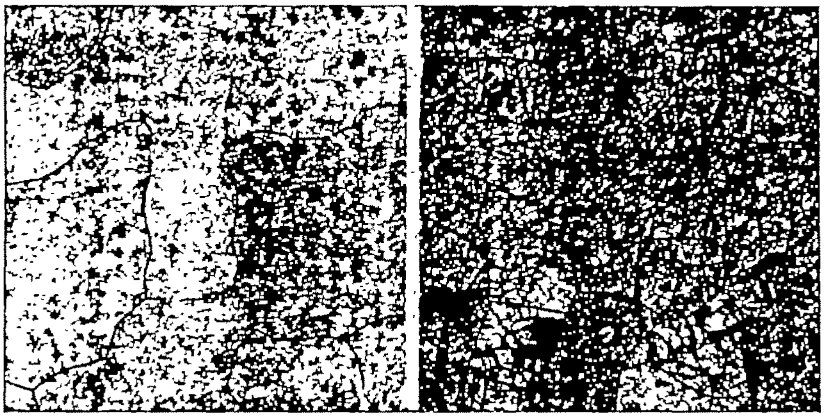
Columbia University, New York, N.Y.

AND

J. INTRATER

College of Engineering, Rutgers University, New Brunswick, N.J.

PREVIOUS observations of the intergranular corrosion of high-purity aluminium in hydrochloric acid have involved the general high-angle grain boundaries, and only superficial attack of the low-angle and sub-grain boundaries has been noted, except after prolonged anodic treatment[1]. We have observed that the sub-grain boundaries (as well as the low-angle grain boundaries) of properly heat-treated specimens are particularly susceptible to



Figs. 1 and 2. Effect of quenching-rate on attack of the sub-grain and low-angle grain boundaries after four days in solution. Annealing temperature 600° C. (1) rapid water quench; (2) inefficient quench obtained by sealing the specimen in a glass tube and quenching in liquid nitrogen. (× 8)

corrosion in 7 per cent hydrochloric acid containing about 0·5 part per million of copper (added as cupric chloride). The attack noted after several days exposure is deep and selective, so that entire sub-grains become undermined and fall out of the specimen (Fig. 2). Although the corrosion of the sub-boundaries in this solution is still somewhat slower than that of the high-angle grain boundaries and increases in a general way with increasing orientation difference, the behaviour is distinctly different from that observed when the metallic impurity content of the acid is low; in this case, the acid strength must be increased to 20 per cent to obtain comparable rates of corrosion for high-angle boundaries (penetrations of order 1 mm. a week) and the relative dependence of the susceptibility to corrosion on orientation is then very strong[1] regardless of the heat treatment[2], and the sub-grain boundaries are only superficially attacked even after prolonged exposure.

Corrosion of sub-grain boundaries in 7 per cent hydrochloric acid containing 0·5 p.p.m. copper has been observed so far in aluminium ranging in purity from 99·97 to 99·996 per cent. The susceptibility to corrosion is dependent on heat treatment; it is minimized by a rapid quench and favoured by an inefficient quench from the annealing temperature. The latter was conveniently achieved by sealing the specimen in a glass tube and quenching in liquid nitrogen. The strong influence of heat treatment is illustrated in Figs. 1 and 2. In this lot of 99·98 per cent aluminium, annealing of the material as supplied (hard-rolled) produced large grains in which the principal sub-structure was coarse and easily observed. In specimens such as that shown in Fig. 2, the small-angle boundaries that are attacked after proper heat treatment correspond to orientation differences from several degrees to at least as low as 10 min.

The variation of the susceptibility of sub-boundaries to corrosion with the rate of cooling from the annealing temperature is presumed to involve the tendency of certain impurity (that is, solute) atoms to concentrate near these boundaries, as postulated by Lacombe and Berghezan[3] for the susceptibility to etching of sub-boundaries in aluminium–zinc alloys produced by ageing air-cooled specimens at room temperature. An appreciable concentration of solute atoms adjacent to the sub-boundaries cannot be produced in material of relatively high purity cooled from a high temperature at a relatively high rate unless these atoms are strongly attracted. The attraction of a solute atom to the region adjacent to a sub-boundary that can result from a difference of atomic size and an interaction with the stress field of the edge components of the dislocations composing the sub-boundary does not appear to be sufficiently great, as estimated from the treatment of Cottrell[4] for an isolated edge dislocation, to account by itself for the observed effects. It is hoped that further study of the influence of composition and heat treatment will provide additional information on this point.

The 7 per cent hydrochloric acid corroding agent containing copper is valuable as an etch fluid for revealing the sub-structure of properly heat-treated specimens. We have made some observations of sub-structures produced by bending single crystals or coarse-grained specimens (prepared by the strain-recrystallization method) and annealing at high temperatures. In general, boundaries running in all directions are observed even where constraints due to neighbouring grains are absent. An example is given in Fig. 3. This shows the sub-boundaries produced in two grains of a coarse-grained specimen, in which the lower grain covers the width of the specimen, together with the subdivided Laue spot obtained in a back-reflexion photograph taken in the lower grain. The axis of bending is parallel to the bottom edge of the figure. When the principal sub-boundaries run more or less parallel to the axis of bending, as in the lower grain, the difference of orientation across a sub-boundary is roughly as expected from the bend radius and the mean spacing of the sub-boundaries.

To date, it has been verified by X-ray measurements that boundaries where the difference of orientation is as small as 5 min. are susceptible to corrosion in this solution; this does not appear to be the lower limit. Corrosion of sub-boundaries in a generally similar manner has been obtained by substituting 100 p.p.m. iron for the copper added to the acid and also by anodic treatment (similar to that used by Lacombe and Yannaquis[1]) in 7 per cent

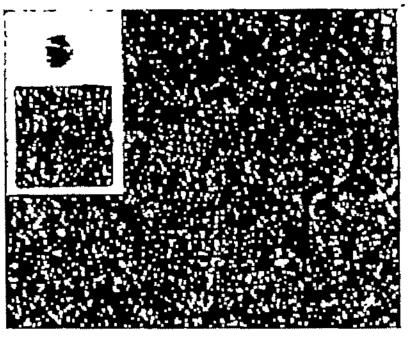


Fig. 3. Sub-boundaries in two grains revealed after four days in solution. Convex surface of coarse-grained sheet bent to a 20-cm. radius at room temperature and annealed at 645° C. The grain boundary is indicated by arrows. (× 8.) Inset shows a back-reflexion Laue spot (× 1½) together with the region of the lower grain (× 8) in which the X-ray photograph was taken. Specimen to film distance, 9 cm.; diameter of irradiated area, 1·5 mm.

hydrochloric acid without additions at current densities in the neighbourhood of 10 m.amp./dm.[2]. With these methods also, the sub-boundaries are strongly attacked only after the proper heat treatment. The minimum difference of orientation, however, is slightly larger than is required when acid with added copper is used as the corroding agent. All these methods are capable of revealing boundaries for which the difference in orientation is smaller than that at which the aqua regia plus hydrofluoric acid etch fluid[5,6] is effective. By using several of the available techniques, it is possible to obtain some information concerning the magnitudes of the differences of orientation at the various sub-boundaries of a specimen. STRUCTURES OF MOLECULES AND CRYSTALS OF FLUOROCARBONS

By C. W. BUNN and E. R. HOWELLS
Imperial Chemical Industries, Limited, Plastics Division,
Welwyn Garden City, Herts

POLYTETRAFLUOROETHYLENE[1] appears to be a chain polymer $(\text{—}CF_2\text{—})_n$ of very high molecular weight, of the order of half a million[2]. The powdered material, as produced in the polymerization reaction, is highly crystalline below 20° C. The 'melting point'—the first-order transition from a partly crystalline to a completely amorphous structure—is about 330° C.[3,4], very much higher than that of the corresponding hydrocarbon polymer—132° C.[5], 136·5° C.[6]; but at 20° C. the fluorocarbon polymer shows another first-order transition involving a 1 per cent change of density, which is shown by X-ray diffraction patterns[4] to be due to a partial disordering of the crystalline regions. The occurrence of a reversible first-order transition involving disordering at a temperature so far below the 'melting point' (actually about half the absolute 'melting point') is unique among polymers, and directs increased attention to the structure of the molecules and of the crystals, both below and above the 20° C. transition.

It is also interesting that on closer examination the room-temperature transition has been found to be composite: although most of the change of density occurs at 20° C., there is an additional smaller change at 30° C.[7,8].

X-ray diffraction photographs of drawn fibres show that below 20° C. (Fig. 1*a*) the pattern is a typical 'fibre diagram' of a crystalline polymer in which the crystals are oriented with the chain direction of the molecules approximately parallel to the direction of drawing. The chain repeat-distance, calculated from layer-line spacings, is 16·8 A.; equatorial reflexions fit a pseudo-hexagonal projected cell-base with $a = b = 5{\cdot}54$ A. and $\gamma = 119{\cdot}5°$. The other unit cell parameters are still in doubt; but the general features of the diffraction pattern give very definite indications of the molecular configuration. The distance 5·54 A. and the very great strength of the 100 reflexion indicate a simple packing of rod-like molecules. A fully extended chain of singly linked carbon atoms has a plane zigzag character (as in polythene[9] and many other chain molecules); but in the fluorocarbon polymer the long-chain repeat-distance indicates some departure from a simple plane zigzag. The essential zigzag character is, however, revealed by the very strong near-meridian reflexions on the 6th and 7th layer lines, which indicate a sub-period between one-sixth and one-seventh of the true period, namely, 16·8/6·5 = 2·6 A., which is about the span of one zigzag of a carbon chain. That there are indeed 6½ zigzags in the chain repeat is confirmed by diffraction photographs taken with the fibre axis oscillating at appropriate angles to the X-ray beam; such photographs show one, and only one, reflexion from a plane perpendicular to the chain axis, and this (an extremely strong one) has a Bragg spacing of 1·294 A., one-thirteenth of the full chain repeat. The fact that there is only one such reflexion indicates that the CF_2 groups are equally spaced along the chain, and this suggests a regular helix; and the (at first sight) curious number of 6½ zigzags in the repeating unit receives a simple explanation if we imagine a plane zigzag twisted 180° in 16·8 A. or 13 chain atoms. A full 360° twist of the chain occurs in 33·6 A., 13 zigzags or 26 chain atoms, but the actual period is half this, because a zigzag consists of two lines of atoms, and a half twist brings the fourteenth atom on the second line directly above the first atom on the first line (Fig. 2). There are other ways of describing this helix; thus successive carbon atoms lie on a helix of six turns in 16·8 A.; but the first description (of the twisted zigzag) is stereochemically the most appropriate, as it refers to the bond structure.

Confirmation of this 13-atom helix is indicated by a group of fairly strong reflexions near the equator, on the second layer, with spacings 2·0–2·4 A., from planes inclined 15–20° to the chain axis; fluorine atoms attached to such a helical carbon chain fall approximately on planes having this spacing and orientation—in other words, the molecular transform has a maximum in this region.

Calculations of layer-line intensities for various types of helical (twisted zigzag) chains, made by the Bessel function method[13], show that the helix described above is the only one which will account for the observed intensities, and give the radius of the fluorine helix as 1·64 A. (± 0·05) and that of the carbon helix as approximately 0·42 A.

When the temperature is raised to 25° C., the diffraction pattern changes profoundly (Fig. 1*b*): equatorial reflexions, and those on the 6th and 7th layer lines, remain sharp (in fact, become actually sharper); but all those on intermediate layer lines become very diffuse, groups of reflexions being converted into broad areas of diffuse scattering. This last fact—that the areas of diffuse scattering are in the same places as previous groups of sharp reflexions—shows that the molecular configuration is unchanged; and this is confirmed by the spacing of the 13th order of the chain period, which remains precisely the same as it was below 20° C. (1·294 A.). We have found no evidence of an increase of chain period reported by others[10]. The disordering, therefore, affects only the positions of the molecules, not their configuration. The lateral spacings are slightly

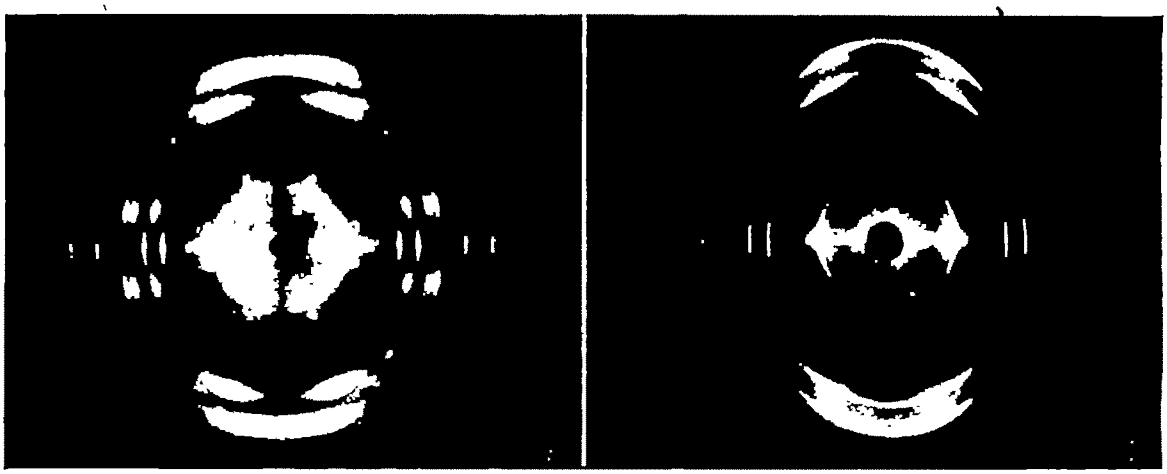

Fig. 1. X-Ray diffraction photographs of polytetrafluoroethylene : (a) at 10° C. ; (b) at 25° C.

increased (the projected cell-base is hexagonal with $a = 5 \cdot 61$ A. and $\gamma = 120°$), but the sharpness of the equatorial reflexions shows that the side-by-side packing is highly regular. The disorder must therefore consist of a variable displacement of the molecules along their chain axes, or a variable rotation about their chain axes. The fact that the 6th and 7th layer-line reflexions are sharp shows that any longitudinal displacement can only be in steps equal to the zigzag span. Variable rotation about the chain axes without longitudinal displacement would, of course, keep all the CF_2 groups on the same levels, and ensure the sharpness of the 6th and 7th layer reflexions. It does not appear to be possible to distinguish between the two alternative types of disorder, which in the polymer lead to precisely the same semi-disordered crystal structure.

At 35° C. (that is, above the subsidiary transition at 30° C.) the equatorial reflexions remain sharp, but the 6th and 7th layer reflexions become diffuse or disappear ; this means that CF_2 groups are no longer on exactly the same levels. The molecular interpretation of the two transitions suggested by these facts is therefore that the main 20° C. transition is due either to rotation around the chain axes or longitudinal displacement in precise steps equal to the zigzag span, while the subsidiary 30° C. transition is due to longitudinal displacements which are not in precise steps. Up to 150° C. the strong 6th and 7th layer reflexions become more and more diffuse as the temperature rises, while the equatorial reflexions remain sharp ; evidently the longitudinal displacements become more and more random.

Crystals of perfluorooctane, $C_{16}F_{34}$, which are flakes of hexagonal outline, have been examined by the same methods. A crystal rotated around the normal to the flake gives, at room temperature, an X-ray diffraction pattern which is strikingly similar to that of the high-polymer fibre well above 30° C. : there are sharp equatorial reflexions which fit a hexagonal projected cell-base, and elsewhere, very diffuse scattering having the same pattern as in the high polymer. Evidently the molecules have essentially the same helical configuration as those of the high polymer. The pattern differs from that of the high polymer, however, in showing meridian reflexions which are successive orders of a spacing of 23·1 A., representing the limited length of the molecules. Oscillation photographs show that the higher orders of this chain spacing are appreciably broadened ; there is evidently some disorder in the direction of the chain axes.

The diffraction pattern changes to the sharp pattern of an ordinary fully-ordered crystal only at very low temperatures : the transition temperature is about −170° C. The behaviour of this fluorocarbon is thus similar to that of the high polymer, except that the transition temperature is even lower (at less than one-third the absolute melting point). It may eventually be possible, from the X-ray diffraction patterns of perfluorooctane, to distinguish between rotations and translations of the molecules in the crystals.

Two very interesting questions arise from these conclusions. In the first place, why is it that the fluorocarbon molecules have a helical chain with a

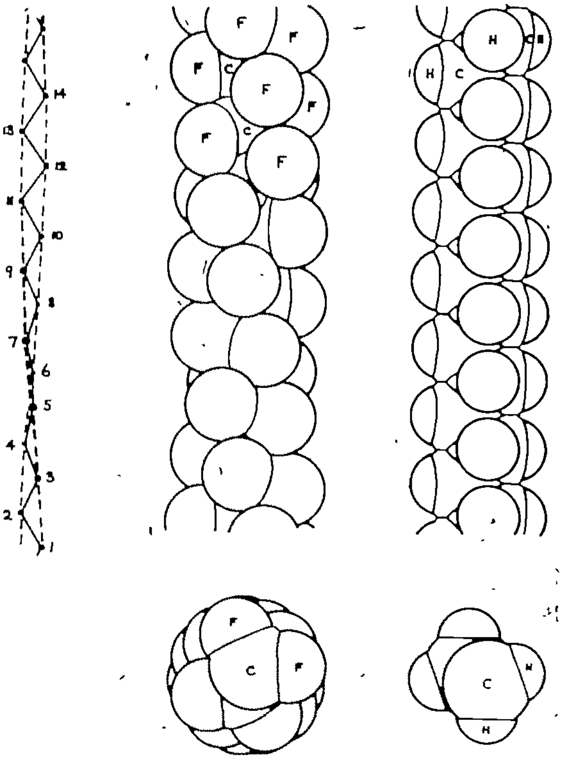

Fig. 2. Left : twisted zigzag chain found in fluorocarbons. Centre : fluorocarbon molecule (side and end views). Right : hydrocarbon molecule

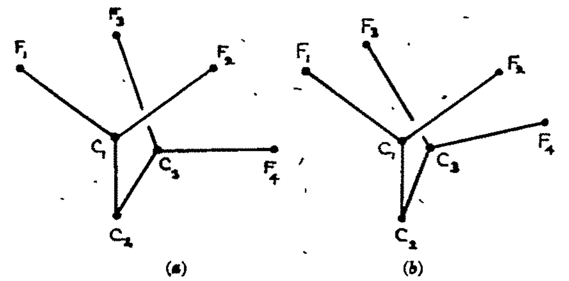

Fig. 3. (a) Configuration giving equal F—F distances ($F_1F_3 = F_3F_4$); (b) configuration actually found

13-atom repeating unit, while the corresponding hydrocarbon molecules have a plane zigzag carbon chain? And secondly, why are fluorocarbon crystals disordered so far below their melting points?

In the plane zigzag chain found in the hydrocarbons[9], the span of the zigzag is 2·539 A. Hydrogen atoms attached to next-but-one carbon atoms are also at this distance from each other. Since the van der Waals radius of hydrogen is 1·1–1·2 A., there is ample room for these atoms—in fact, they are not in contact but separated by a gap (see Fig. 2); but the van der Waals radius of fluorine is 1·35 A.; double this figure is 2·70 A., so that fluorine atoms attached to a plane zigzag carbon chain would be overcrowded. The helical structure is presumably due to rotation around the chain-bonds which takes place to increase the distance between the fluorine atoms. It is interesting to find, however, that although satisfactory distances between fluorine atoms could be attained by a rotation which would bring one fluorine atom (F_3 in Fig. 3a) equidistant from the two (F_1 and F_4) on the next-but-one carbon atom, this is not what actually happens; instead, a smaller rotation occurs (giving unequal F—F distances), and the remainder of the required increase of the shortest distance is provided by an increase of the zigzag span from 2·539 A. (the figure for hydrocarbons) to 2·595 A., an increase which is presumably due to an opening of the $\underset{C\qquad C}{\overset{C}{\diagup\;\diagdown}}$ bond angle (to 116°), since this is much easier than stretching the C—C bonds. The limitation of the rotation may be due to repulsion between fluorine atoms and next-but-one chain carbon atoms (F_3 and C_1 in Fig. 3b) or to a bond-orientation effect (as distinct from atom repulsions) which favours staggered configurations of which the plane zigzag chain is the simplest example[11].

The order–disorder transition which occurs at room temperature in the high polymer is evidently not a phenomenon peculiar to the polymer, for the same type of transition is found in perfluorooctane, again at a temperature far below the absolute melting point; it is evidently due to some feature of the structure of a fluorocarbon chain. The transition may be analogous to the change that occurs[12] in paraffin hydrocarbons from C_{21} to C_{27} (but not in the high polymer[13]) a few degrees below the melting point, a change that is thought to be due to the onset of rotation of the molecules about their long axes (though the only evidence is the change to hexagonal symmetry). In the fluorocarbons we have much more definite evidence for disorder, and, above all, the transition occurs far below the melting point. Molecular models show that the fluorocarbon chain is more 'streamlined' than the hydrocarbon chain (see Fig. 2) in the sense that the general shape is more nearly cylindrical and the projections and depressions in the profile are smaller in relation to the cross-sectional area of the molecule. The close approach to cylindrical shape may be the simple explanation of the existence of disordered crystals at such low temperatures. Both rotations around the chain axis and longitudinal translations would be facilitated by such a streamlined shape.

Many crystals composed of molecules of approximately spherical or cylindrical shape suffer transitions which appear to be due to the onset of molecular rotation[14-19]. For some spherical molecules (camphor and certain derivatives) and flat cylindrical molecules, the transition temperature is far below the melting point[14,16]; but for long-chain molecules (aliphatic hydrocarbons, acids and alcohols) molecular rotation usually occurs (if at all) only a few degrees below the melting point[12,18]. The fluorocarbons are quite exceptional among chain compounds in showing evidence of disorder very far below their melting points. The controlling factor is probably the size of the projections and depressions in the profile, in relation to the diameter of the molecule: camphor and its derivatives have a predominantly hydrocarbon surface, characterized by projections and depressions of similar size to those in chain hydrocarbons, but owing to the greater diameter of the cage-like camphor molecule, the projections and depressions are relatively smaller. Among slender chain molecules it is only the fluorocarbon surface which is sufficiently smooth to permit rotation at very low temperatures.

Polytetrafluoroethylene has other exceptional properties; in particular, its coefficient of friction is remarkably low—much lower than that of polythene—and indeed it appears to be unique among plastics in this respect[21,22]. It seems possible that this also is connected with the disorder transition at room temperature, and is in fact due to the same feature of the molecular structure—the smooth profile of the molecule, which permits easy slip of one molecule past another and easy gliding on the crystal planes which are parallel to the chain axes.

We wish to thank Dr. R. N. Haszeldine for providing a specimen of perfluorooctane. [July 12.

Pentamethonium as an Adjuvant to Atropine in the Therapy of Paraoxon Poisoning

Paton and Perry[1] demonstrated a competitive antagonism between acetyl choline and pentamethyline *bis*-trimethyl ammonium dibromide (pentamethonium), at ganglia, and this suggested that pentamethonium might be of value in treating poisoning with anticholinesterases such as diethyl 4-nitrophenyl phosphate (paraoxon). Douglas and Matthews[2] used pentamethonium in cats poisoned with tetraethyl pyrophosphate (TEPP), and showed that it improved the contractile power of the diaphragm. We now have evidence that pentamethonium bromide significantly increases survival of fully atropinized animals—mice, rabbits and cats—poisoned with paraoxon.

Table 1. LD50 Values for Female Mice given Intravenous Injections of Paraoxon Alone and Together with Antagonists

Treatment	No. of mice injected	LD50 paraoxon (mgm./kgm.)	95 per cent fiducial limits	Slope
Paraoxon alone	101	0·48	0·46–0·49	22·54 ± 3·43
„ + 1 mgm./kgm. atropine	55	0·56	0·55–0·57	44·74 ± 8·35
„ + 5 „ „	122	0·67	0·62–0·91	11·90 ± 1·92
„ + 10 „ „	110	0·89	0·82–0·97	7·78 ± 1·63
„ + 20 „ „	50	1·00	0·88–1·13	7·51 ± 1·82
„ + 30 „ „	60	0·94	0·86–1·03	10·23 ± 2·58
„ + 10 „ „ + 10 mgm./kgm. pentamethonium	130	2·28	1·86–2·80	2·62 ± 0·47

In mice a quantitative expression of the therapeutic potency of pentamethonium was obtained by plotting dose-effect curves for the intravenous injection of: (1) paraoxon alone, (2) paraoxon plus various doses of atropine, and (3) paraoxon plus a full dose of atropine (10 mgm./kgm.) plus pentamethonium. The LD50 value for each treatment was calculated by the probit method and these, along with their 95 per cent fiducial limits and the slopes, are given in Table 1. For the test with pentamethonium, a dose of 10 mgm./kgm. of atropine was selected. This was not the optimum of the doses of atropine tested; but the difference in protection afforded by 5, 10, 20 and 30 mgm./kgm. of atropine was insignificant. Adding pentamethonium to the atropine increased the LD50 over the highest figure obtained with atropine alone 2½ times. As the protective action improved, the slope of the regression line became flatter, and when pentamethonium was injected, survival occurred in a high proportion of mice given more than 4 mgm./kgm. of paraoxon.

Experiments with rabbits and cats anæsthetized with a chloralose – urethane mixture gave similar results. Sufficient paraoxon was injected into these animals to cause severe respiratory depression in spite of a full dose of atropine given simultaneously. To some nothing more was given, and these all died within thirty minutes. To others additional atropine was given intravenously, and these too died. To others again pentamethonium was given intravenously and these all recovered within the limits of an acute experiment (see Table 2).

Table 2. Effect of Pentamethonium on Survival of Cats and Rabbits

	Dose of paraoxon (mgm./kgm.)	No. of experiments	Pentamethonium	Result
Cat	1·75	3	No	Died
Cat	1·75	3	Yes	Recovered
Cat	2·0	2	Yes	Recovered
Rabbit	1·0	3	No	Died
Rabbit	1·0	3	Yes	Recovered

An explanation of the beneficial effect of pentamethonium in these two species was forthcoming in the shape of an immediate increase in the respiratory volume. Its effect on the blood pressure, as is well known, was to lower it; but following an initial fall, a slow but steady rise set in. The respiratory volume, on the other hand, rose steeply in all experiments, reaching a peak within one minute of the injection. A limited fall then took place, and it was not until 15–20 min. later that it began to rise again.

Fig. 1 shows the respiratory volume in three typical experiments with the cat, plotted as a percentage of the average volume measured for 30 min. or more before injection of the drugs. The same initial dose of paraoxon and atropine was given to all three, and the effect on the respiratory volume of injecting pentamethonium or further atropine can be compared with that of no treatment at all. It will be seen that further atropine, so far from im-

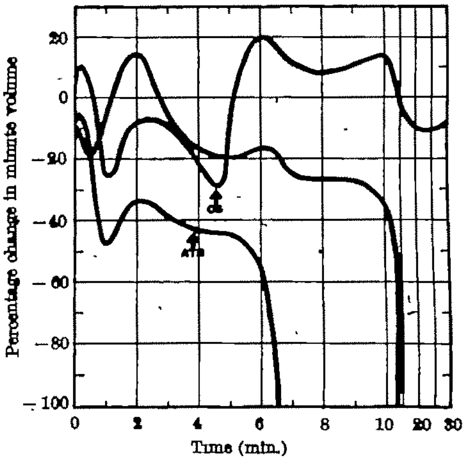

Fig. 1. Effect of pentamethonium on the respiratory minute volume of the cat. In all three experiments paraoxon (1·75 mgm./kgm.) together with atropine sulphate (2·0 mgm./kgm.) was injected intravenously at zero time. The arrows denote the time at which pentamethonium bromide (C5) (10 mgm./kgm.) was injected intravenously in one experiment, and atropine sulphate (2·0 mgm./kgm.) in another

proving the animal's condition, actually precipitated respiratory arrest.

Excretion in Human Urine of an Unknown Amino-acid derived from Dates

IN the course of an investigation with the aid of paper chromatography of the genetics of amino-acid excretion in man, it was observed that some individuals excreted large quantities of an unknown ninhydrin-positive substance. Upon inquiry concerning the diet of these individuals, it was found that dates had been eaten in all cases. Seven individuals were selected who had not eaten dates for at least a month, and chromatograms of their urine were prepared. In no case was the 'date spot' observed. These seven individuals were then fed eight to ten dates in the evening, and the following morning a sample of their urine was collected. Another urine sample was obtained the following morning. In every case the chromatograms of the first urine specimen showed quite clearly the 'date spot'. The chromatograms of the urine specimens produced on the second day after eating dates showed only a trace of this spot, or failed to show it altogether.

The unknown substance which produces the 'date spot' moves on the two-dimensional chromatograms in phenol–lutidine solvents to a location almost identical with that of α-amino-*n*-butyric acid. However, in butanol–acetic (4 : 1 : 1) solvent, this substance moves much less than α-amino-*n*-butyric acid, its R_F being about 0·25. The colour of the spot after developing with ninhydrin and heating also differentiates it from α-amino-*n*-butyric acid. The 'date spot' is clear blue, resembling somewhat the colour given on similar chromatograms by aspartic acid, rather than the violet or purple given by most other amino-acids. This blue becomes gradually more purple after standing for several days.

We have also investigated the occurrence of this substance in the date, and find that it is present in the free form and does not appear to increase in amount after acid hydrolysis. This suggests that the substance is an amino-acid and not a peptide. A copper complex test has also been run indicating that the substance is an α-amino-acid.

It is interesting that the amino-acid under consideration is excreted apparently unchanged, since from superficial appearances its excretion appears to be quantitative. This is a rather unusual situation for amino-acid metabolism in the human body; but we have no positive proof that the excretion is strictly quantitative.

This work was carried out by one of us (S. G.) during the tenure of a U.S. Public Health Service postdoctoral fellowship.

A Peculiar Nutritional Dermatitis in Pigs

IN the course of our advisory duties, we have frequently encountered a number of cases of a peculiar dermatitis in pigs. The condition develops in pigs of about 10–12 weeks of age and is characterized initially by the development of red blotches under the skin of the hocks, spreading up the hind legs into the groin and over the belly and eventually over the back and ears. The dermatitis is accompanied by an acute irritation; the pigs become very uncomfortable and rub continually against the sides of the sties. This rubbing usually breaks the skin, resulting in the formation of extensive scabs. Appetite is adversely affected and the pigs make little or no live-weight gain. Natural recovery is very slow, and as a result of the condition, the pigs may take several weeks longer to reach the bacon factory.

The condition develops on both home-mixed and proprietary rations, with or without added antibiotics, and cannot be controlled by normal oily or powder dressings, dipping, bathing or spraying with insecticide preparations. It has only been found when pigs are dry-fed, even though drinking water is freely available.

The dermatitis can be quickly controlled and finally obviated by changing the affected pigs to wet-feeding. The inclusion of fodder beet or potatoes in the diet results in a marked improvement; but the recovery is not so dramatic as that which occurs when a wet-feeding practice is employed. On wet-feeding, appetite is quickly regained, the scabs slowly disappear and the pigs begin to put on weight again.

There is as yet no evidence of the fundamental cause of the condition or a valid explanation of the mechanism of the empirical cure; but we are putting these observations on record in the hope that they will be of value to others who may have encountered the condition, which would appear to be of more widespread occurrence than has hitherto been recognized.

Thanks are due to Col. J. E. B. Freeman, Buxhall Vale, Stowmarket, for allowing us facilities for experiments and for his careful observations.

Action of Squalene upon Carcinogenic Hydrocarbons

SQUALENE is an unsaturated triterpenoid hydrocarbon which was originally isolated from the liver oil of the shark[1]. Among its other occurrences, it was found to be present in the fat from ovarian dermoid cysts[2]. In an investigation on the role of sebum in carcinogenesis, squalene was found to be present in horse smegma and in human ear wax and hair oil[3,4]. MacKenna and co-workers found it in skin surface sebum[5].

The possible role of squalene as a protective agent in sebum is under investigation in this laboratory. It has already been shown to be fungistatic *in vitro* against certain dermatophytes[6]. This appears to be related to rapid peroxide formation which occurs when squalene is exposed to air.

Squalene was purified by passage through alumina. 3-Methylcholanthrene, 7,12-dimethylbenz[*a*]anthracene and benzo[*a*]pyrene (from Eastman Organic Chemicals) were purified before use. 100-mgm. samples of freshly purified squalene containing 500 μgm. of carcinogen were exposed at 37° C. in 35 c.c. round-bottomed centrifuge bottles. After the desired time interval, 10 c.c. of methanol was added and then 3 c.c. of cold 1 *N* sodium hydroxide. The mixture was then extracted six times with 5-c.c. portions of petroleum ether. The solvent was removed by evaporation under reduced pressure. Aliquots were taken for fluorometric determination of the hydrocarbon content and for squalene determination[4].

This procedure permitted a quantitative recovery of squalene and each of the hydrocarbons when the extraction procedure was carried out immediately. Complete, or nearly complete, recovery of the hydrocarbons was obtained when mineral oil replaced squalene and the period of exposure at 37° C. was as long as one month.

Only 7 per cent of 7,12-dimethylbenz[*a*]anthracene could be recovered after exposure to squalene for one week at 37° C. Nothing could be recovered after the second week. In the case of 3-methylcholanthrene 30 per cent remained after the first week and only traces were found afterwards. The possible presence of a fluorescence-quenching substance was ruled out. On the other hand, even after five weeks of exposure, 92 per cent of benzo[*a*]pyrene was recoverable. This substance exerted a profound antioxidant activity, for squalene could still be recovered in nearly theoretical amounts. During this period squalene alone was almost completely oxidized. 7,12-Dimethylbenz[*a*]anthracene exerted almost no antioxidant effect although 3-methylcholanthrene was somewhat inhibitory.

Bernheim *et al.*[7] demonstrated that carcinogens inhibit fatty-acid oxidation in the epidermis of the mouse and suggest that carcinogens, by inhibiting peroxide formation, may produce conditions favourable for growth. The observation with benzo[*a*]pyrene is in conformity with the suggestion of these workers. Mueller *et al.*[8] reported some time ago that benzo[*a*]pyrene and 3-methylcholanthrene are destroyed in oxidizing unsaturated fatty acids. It remains to be seen whether the products of the reaction of 3-methylcholanthrene and 7,12-dimethylbenz[*a*]anthracene with squalene are still carcinogenic and whether this reaction is related to the role of squalene in sebum.

Cortisone in Relation to Infection and Tumour Growth

Nicol, Helmy and Abou-Zikry[1] showed that œstrogens stimulate the reticulo-endothelial macrophages in the spleen, liver, and lymph nodes, and that prolonged œstrogen treatment or stimulation by large doses of œstrogen appears to lead to mobilization of the macrophages in these organs. The reticulo-endothelial system is an important defence mechanism against malignant tumours in general[2,3], and its stimulation therefore probably increases the general defence of the body against tumour growth.

In view of the recent reports that patients being treated with cortisone are more susceptible to infection, and that cortisone enhances the spread of transplanted tumours in animals, it seemed desirable to study the effect of this hormone on the reticulo-endothelial system.

Seventeen male guinea pigs aged about one year were used for the present investigation. The reticulo-endothelial macrophages were studied by giving all the animals one daily injection of trypan blue subcutaneously for the last six days prior to being killed by chloroform. The dosage of the dye was calculated on the basis of 0·8 ml. of a 1 per cent solution in distilled water per 100 gm. body-weight. Seven of the animals were given dye only and were used as controls. The ten remaining animals each received 5–10 mgm. of cortisone (Roussel Laboratories, Ltd.) intramuscularly once daily for one to four weeks in addition to the dye. Specimens were taken from the spleen, liver and lymph nodes and fixed in Heidenhain's 'Susa' fluid. Sections were cut at 10 μ thick and stained with dilute carbol-fuchsin or weak eosin. The activity of the reticulo-endothelial system in the organs studied was measured by the number of dye-bearing cells and the intensity of the vital staining.

The results are as follows. In two of the four animals which received 5 mgm. of cortisone once daily for seven days, the intensity of the vital staining was reduced in the macrophages of the spleen compared with the results in the controls; but no appreciable effect was observed in the macrophages of the liver and lymph nodes. In the remaining animals which received 5 mgm. of cortisone daily for seven days, then 10 mgm. for a further two to three weeks, the reduced intensity of the vital staining in the macrophages of the spleen was still more marked; in those which received hormone treatment for four weeks, the vital staining was also slightly reduced in the macrophages of the liver and lymph nodes.

These preliminary results show that cortisone depresses the activity of the reticulo-endothelial macrophages especially in the spleen, and in this manner probably lowers the defence of the body against infection and new growths.

For this research we gratefully acknowledge the gift of cortisone by the Medical Research Council.

Chemotherapeutic Experiments with Natural Constituents of the Body

Borsook and co-workers[1], from redox potential measurements, claimed in 1935 to have found that dehydroascorbic acid and reduced glutathione can form an intermediate compound *in vitro* from which ascorbic acid can be regenerated. The occurrence of this reaction in living organisms was contested by Bersin and others[2], who considered that the formation of ascorbic acid from dehydroascorbic acid was effected by an enzyme. Neither the supposed intermediate compound nor the enzyme has so far been actually shown to exist.

The fact that ascorbic acid itself has a bactericidal action was shown by von Gagyi[3] and myself[4]. Cysteine has been used in the treatment of hepatitis and also in the treatment of mustard gas burns of the skin; for which latter purpose I devised[5] an electrophoretic method. As is well known, mustard-gas burns in their clinical course strongly resemble X-ray injuries, and cysteine has also been used for the treatment of injuries of this kind. Presumably the effect is due to detoxication of toxic substances resulting from the irradiation. In the same way cysteine has been used for diminishing the toxic effects of nitrogen mustard when this is employed in cancer therapy[6].

The results referred to above seem to indicate the probability of a chemotherapeutic activity of cysteine and ascorbic acid, and for this reason as early as 1939 a compound of cysteine and ascorbic acid was prepared by me under the direction of Prof. Hans Schmalfuss.

Synthesis of cysteylascorbic acid. 0·02 mol. dried cysteine hydrochloride (Merck) was warmed at 40° for 30 min. with 12 ml. of carefully purified thionyl chloride and the mixture then shaken at room temperature for 4 hr. The acid chloride was then removed by filtration and the product washed with purified acetyl chloride and light petroleum (boiling point 49°) in an atmosphere of nitrogen. The product was added with stirring and in an atmosphere of nitrogen to a suspension of very pure 0·02 mol. sodium ascorbate dried in 300 ml. of thoroughly dried absolute alcohol; the stirring was continued for 4 hr. The undissolved residue was filtered off, and the solution kept overnight in the ice-chest under nitrogen. Next day a small precipitate was removed by filtration and the solution concentrated in a stream of nitrogen at 20 mm. until turbidity appeared; dry ether was added until precipitation of solid was complete; the precipitate is the chemotherapeutically active substance.

For chemical investigation attempts were made to purify the compound by two recrystallizations from alcohol. This purification has so far only been partly successful. The recrystallized compound forms rhombic crystals of questionable disintegration point 157° (found: C, 35·7; H, 4·71; N, 4·9 per cent. $C_9H_{13}O_7NS,H_2O$ requires C, 36·6; H, 5·1; N, 4·7 per cent). The absorption curve in the ultra-violet gave a maximum at 255 mμ in absolute alcohol. Pure ascorbic acid shows a maximum at 245 mμ.

More précise details must await further experiments on the constitution of the compound. By far the most effective compound in bacteriological experiments was finally prepared with a modification of the above-mentioned synthesis, which is referred to later on.

Chemotherapeutic experiments. As experimental animals young mice weighing about 6 gm. were used. The bacterial strains employed were highly virulent, virulence having been increased by five passages through mice.

Since the chemotherapeutic action might also be exercised by a mixture of ascorbic acid and cysteine, the following mixtures and individual substances were studied for their action on intraperitoneal pneumococcal infections of the mouse: (1) an equimolecular mixture of cysteine hydrochloride and sodium ascorbate; (2) the residue obtained by evaporating to dryness an aqueous solution of an equimolecular mixture of cysteine hydrochloride and sodium ascorbate; (3) the same product stirred with light petroleum for several hours; (4) cysteine hydrochloride; (5) the first insoluble residue obtained during the synthesis of cysteylascorbic acid; (6) the residue obtained by evaporating the final solution after precipitation of the cysteylascorbic acid with ether.

Infection was induced by intraperitoneal injection of 0·3 ml. of undiluted culture of *Pneumococcus mucosus*; the various substances to be tested were dissolved in 0·2 ml. saline and injected immediately or within 30 min. of the time of the inoculation. For each experiment two experimental animals and two controls were used. The results are shown in Table 1.

Table 1

Substance No.	50 mgm.	25 mgm	6·25 mgm	12·5 mgm.	3 mgm.	Control
1	− −	+ +	+ +	+ +	+ +	+ +
2	− −	− −	+ +	− −	− −	+ +
3	− −	− −	+ +	− −	− −	+ +
4	− −	+ +	+ +	+ +	+ +	+ +
5	+ +	+ +	+ +	+ +	+ +	+ +
6	+ +	+ +	+ +	+ +	+ +	+ +

+ indicates death

At the same time, and by the same technique, an experiment was carried out with the cysteylascorbic acid, the results of which are shown in Table 2.

Table 2

Experiment No.	30 mgm.	12 mgm.	8 mgm.	4 mgm.	2 mgm.	1 mgm.	Control

2	*LL*	*LL*	*LL*	*LL*	*LL*	*LL*	+ +

L = survived

In a further experiment, groups of four mice were inoculated with 30,000 lethal doses of another strain of pneumococcus and treated similarly with the cysteylascorbic acid at different dose-levels with the results shown in Table 3.

Table 3

Experiment No.	20 mgm.	15 mgm.	10 mgm.	5 mgm.	Control
3	*LLLL*	*LLLL*	*LLLL*	+ + *L* +	+ + + +

Finally, groups of three mice were treated with 10 mgm. of cysteylascorbic acid 1½, 3 and 4½ hr. after inoculation. All treated animals survived; the four controls died after 12 hr. In all the experiments with pneumococcal infection taken together, 107 control animals died, mostly within 12 hr., and 45 treated animals survived.

In vitro, the cysteinylascorbic acid inhibited the growth of the pneumococcus employed down to a concentration of 450 μgm. per ml. as compared with inhibitory concentrations of aureomycin and streptomycin of 25–250 μgm. per ml.

Experiments with Staph. aureus, Strep. pyogenes haemolyticus and Esch. coli. Similar chemotherapeutic experiments were carried out with mice infected with two lethal doses of a virulent strain of *Staph. aureus*. Survival of all animals was obtained with doses of cysteinylascorbic acid as low as 0·075 mgm., and again, as in the case of the pneumococcus infection, doses of 10 mgm. of the compound given 1¼, 3 and 4½ hr. after inoculation were sufficient to protect mice against heavy doses of the organism. The strain of *Staph. aureus* employed was resistant to penicillin, aureomycin and streptomycin.

Preliminary experiments with *Streptococcus* and *Esch. coli* indicate a similar degree of chemotherapeutic activity. Most of the bacteriological experiments were carried out by the director of the Bacteriological Department, Dr. Hans Lodenkämper, with the assistance of Dr. Stienen, Lohmuhlenkrankenhaus, Hamburg. I myself was responsible for the first bacteriological experiments.

Summary. The experiments described above leave no doubt concerning the chemotherapeutic activity of the cysteylascorbic acid, although this compound has not yet been prepared in a completely pure state. Since the experiments reveal a new principle, namely, the possibility of the chemotherapeutic employment of natural constituents of the body, it is considered desirable to publish the observations although the chemical constitution of the compound is not yet certainly established.

The ultra-violet absorption spectrum and polarographic analysis of the compound make it likely that it is a cysteyl ester of ascorbic acid, the attachment of the cysteine residue being at C_2 or C_3. The yield of the compound obtained by the method described is 15–20 per cent. Possible alternative synthetic methods for its preparation are now being studied. The toxicity of the compound for mice is negligible since a dose of 3 gm./kgm. is tolerated without ill-effect. The effect could probably be explained through the formation of a complex compound of the cysteine with the copper of the serum and certain copper-containing ferments of bacteria. The copper is, according to Heilmeyer and Keiderling[7], much increased after infections, whereas the iron is diminished.

It seems possible that the compound may find a use in diminishing the toxicity of nitrogen mustard and in preventing injury from X-irradiation; experiments to test these points are in view.

Secretion of Juvenile Hormone by the Corpus Allatum of *Calliphora*

IT is now generally accepted that metamorphosis in insects is prevented throughout the larval stages by the secretion of the 'juvenile hormone' by the corpus allatum; but this has never been quite satisfactorily proved in the Diptera. Vogt[1] obtained some evidence that the corpus allatum restrains the development of the imaginal disks in the early stages of *Drosophila*. She also showed[2] that the corpus allatum of young *Drosophila* larvæ would induce yolk formation in adult *Drosophila* deprived of the corpus allatum; and since the yolk-forming hormone is the same as the juvenile hormone[3], this finding suggests that the hormone is present in the *Drosophila* larva. Vogt[4] and Possompès[5] also obtained evidence that the corpus allatum of the adult *Drosophila* and *Calliphora* will cause partial and local inhibition in the formation of pupal or adult cuticle.

The problem has been re-investigated by implanting the corpus allatum of *Calliphora* into the abdomen of the fifth-stage larva of *Rhodnius* fed one day previously. Implantation of the corpus allatum (together with the corpus cardiacum) from adult *Calliphora* of either sex, fed on sugar alone or on sugar and meat, resulted in several instances (three out of twenty survivals) in the appearance of a small localized patch of larval cuticle in the resulting adult.

The ring gland together with the central nervous system from second-stage larvæ of *Calliphora*, or the isolated dorsal region of the ring gland of small third-stage larvæ of *Calliphora*, were similarly implanted. Out of fifty-one adult *Rhodnius* surviving, six showed patches of cuticle with more or less well-marked larval characters over the site of the implant. Fig. 1 illustrates one of these patches overlying the implant of the dorsal part of the ring gland of a third-stage *Calliphora* larva.

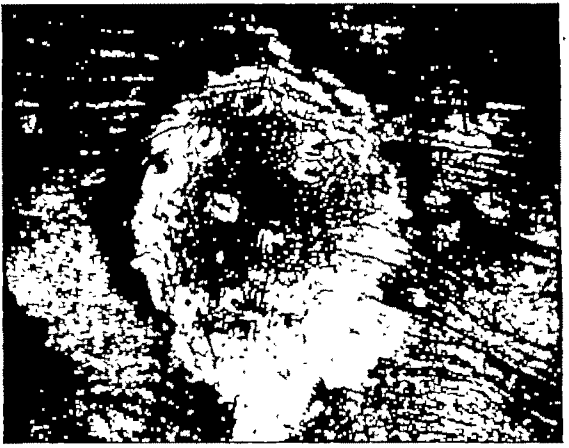

Fig. 1. Part of an abdominal tergite in *Rhodnius* adult with a patch of larval cuticle, showing bristle-bearing plaques and characteristic folding of the epicuticle, overlying an implanted ring gland from a third-stage *Calliphora* larva. The pale patch is just 0·5 mm. wide

These results not only prove the existence of the juvenile hormone in Diptera, but also they provide further evidence of the non-specific character of this hormone.

I am indebted to Mr. P. J. Judge for supplying *Calliphora* larvæ reared under sterile conditions.

Submerged Culture Production of Diphtheria Toxin

It has been shown[1-3] that high-titre diphtheria toxin can be produced by growing the Park Williams No. 8 strain of *C. diphtheriae* in shaking flasks, and one of us[4] has reported the production of 100 Lf. u./ml. toxins in stirred and aerated cultures. Recently, using the latter technique, we have been able to prepare high-titre toxins (Lf. 150–200 u./ml.) by growing the organism for 48 hr. in 14-litre amounts of tryptic digest medium[1] in 20-litre 'Pyrex' flasks stirred by either a glass or a 'Birmabright' (a magnesium–aluminium alloy) stirrer with air bubbling through the cultures from an 'Aerox' filter (porosity *P* 28) at the rate of one-sixth litre of air per litre of medium per minute. Such culture filtrates contain 1,500–1,700 Lf./mgm. protein nitrogen and are, therefore, very suitable starting material for the further purification of the diphtheria toxin. Moreover, the antigen composition of the culture filtrates, concentrated by ultrafiltration, when examined by a gel diffusion test against antitoxin[5], was found to be as complex as in surface-culture filtrates; but the amounts of the contaminating antigens were less, thus explaining the higher purities obtained from submerged cultures.

Further experiments using glass-lined vessels stirred with aluminium 'vortex' stirrers of a type similar to that suggested by Chain[6], with air being passed over the surface of the medium and not through a bubbler or sparger ring, have also given as good results as those obtained with 'Pyrex' glass flasks. Experiments with culture vessels constructed of commercial aluminium have given quite high titre toxins, but such vessels show signs of attack by the culture on continued use, accompanied by a decrease in toxin production. This problem is now under investigation.

Blood Platelets as Carriers of Adrenaline and Noradrenaline

It is now widely accepted that, provided the sympathetic innervation is intact, adrenaline is discharged continuously from the suprarenal medulla, even under basal conditions. Several authors[1] found a basal discharge of 0·03–0·06 μgm./kgm./min. from the two suprarenals of cats and dogs. According to our results[2], the adrenaline arteriovenous difference in man is about 0·5 μgm./l. of blood, which corresponds, as a first approximation, to a rate of utilization of about 0·03 μgm./kgm./min.—a value in good agreement with the established rate of adrenaline discharge.

An arteriovenous difference of 0·5 μgm./l. is compatible with the figures which we find for the concentration of adrenaline in venous plasma, namely, 1·0–1·6 μgm./l. of blood[3]. The validity of the method used has been checked by paper-chromatographic studies which showed that the material estimated could be recovered from the expected positions in yields approximating to those of model experiments, and that the fluorescence developed in the eluates had the expected spectral properties[3].

However, Holzbauer and Vogt[4], on the basis of a biological method, recently came to the conclusion that the adrenaline content of plasma is much lower. They also found that insulin injection increased the plasma adrenaline concentration, whereas we had found the opposite effect[3].

It occurred to us that these discrepancies might be explained, at least in part, by the different methods of blood collection. Holzbauer and Vogt, conforming to the exigencies of the biological method, took every precaution to prevent platelet breakdown, whereas in our method[3] the blood is collected in a hypertonic solution and in untreated glassware, conditions known to lead to the disintegration of the blood platelets. 209 ml. blood was collected in a silicone-coated cylinder containing 3,500 units of heparin dissolved in 1·5 ml. isotonic sodium chloride; 15 ml. was withdrawn and mixed with 5 ml. of a sodium fluoride – sodium thiosulphate solution[3] for estimation by method of Weil-Malherbe and Bone[3], the remainder centrifuged in silicone-coated tubes at ~ 600 *g* for 20 min. Plasma (72 ml.) was separated and half of it recentrifuged at ~ 3,000 *g* for 20 min. Both plasma fractions, and the residue from the second spin, were transferred to untreated glassware and mixed with the sodium fluoride – sodium thiosulphate solution and acetate buffer, prior to chromatography on alumina columns[3]. The eluates from the two plasma fractions were each divided into four parts: one part for estimation by the ethylenediamine method[3] and three parts for estimation according to Lund[7] (one part each for oxidation at *p*H 3·0, oxidation at *p*H 6·5 and for the blank).

It appears from the results shown in Tables 1 and 2 that the substances estimated as adrenaline and noradrenaline by our method are indeed associated, to a large extent, with the blood platelets. When platelet disintegration is avoided, about 70–80 per cent may be removed from plasma by centrifuging and a considerable part may be recovered from the platelet residue.

Table 1. ESTIMATION OF ADRENALINE AND NORADRENALINE (μGM./L. BLOOD) IN 'PLATELET-RICH' AND 'PLATELET-POOR' PLASMA

	Assay by ethylenediamine method (ref. 3)		Assay by Lund's method (ref. 7)	
	Adren.	Noradren.	Adren.	Noradren.
Blood collected in NaF–Na$_2$S$_2$O$_3$ solution	1·46	3·70	1·56*	5·40*
Blood collected in heparin and siliconized glass:				
Plasma spun at ~600 *g*	1·47	4·25	2·37	2·96
Plasma spun at ~3,000 *g*	0·34	1·20	0·36	1·17
Residue from second spin	0·72	2·11		

* These values were determined on a different blood sample collected from the same subject some days previously.

Table 2. EFFECT OF FRACTIONAL CENTRIFUGATION ON PLASMA CONTENT OF ADRENALINE AND NORADRENALINE

Blood (64 ml.) collected in heparin and siliconised glass. Plasma (24 ml.) divided into three parts and two parts re-centrifuged at ~ 3,000 *g* and 12,000 *g*, respectively. Estimation by ethylenediamine method (ref. 6)

	Adrenaline (μgm./l. blood)	Noradrenaline (μgm./l. blood)
Plasma spun at ~ 600 *g*	1·24	5·56
Plasma spun at ~ 3,000 *g*	0·64	3·44
Plasma spun at ~ 12,000 *g*	0·31	1·56

It is also shown in Table 1 that Lund's method[7] gives, in our hands, results which are very similar to those obtained by the ethylenediamine method[6]. The fact that the same result is obtained with two independent chemical methods, both having a high degree of specificity, surely is yet another strong argument in favour of the substances estimated being identical with adrenaline and noradrenaline.

The fraction previously regarded as 'plasma' adrenaline undergoes rapid and extensive changes in response to the injection of various hormones and drugs, to convulsions and to changes in the level of consciousness (natural sleep). In contrast to the adrenaline content of the red blood corpuscles, which is not significantly affected by these stimuli, the adrenaline store of the platelets appears to have important physiological functions. The platelets are already known to harbour histamine, at least in the rabbit[8], and 5-hydroxytryptamine[9]. They thus emerge as a store-house of circulating pharmacologically active amines.

Vitamin B_{12} in Crude Liver Extracts

IN a previous communication[1], we reported that when cyanocobalamin was added to certain crude liver extracts, assays carried out by means of a mutant of *Escherichia coli* gave much lower results than would have been expected from the amount of vitamin B_{12} added, although *Lactobacillus leichmannii* gave fairly satisfactory recoveries. It was suggested that such extracts contained a substance that interfered with the utilization of vitamin B_{12} by *E. coli*. We have since obtained additional results on the nature of this interfering factor, and the publication of two recent papers[2,3] on the presence of bound forms of vitamin B_{12} in human serum and in sow's milk respectively prompts us to put our preliminary results on record.

In the first of these papers, Pitney *et al.*[2] reported that in the assay of human serum for vitamin B_{12} by means of *Euglena gracilis* higher values were obtained after the serum had been heated (confirming an earlier observation by Ross[4]), and that when vitamin B_{12} was added to the serum not more than 50 per cent could be accounted for on subsequent assay. From electrophoretic experiments it was concluded that the α-globulin fraction of human serum was able to bind vitamin B_{12}, forming a complex which did not stimulate the growth of *E. gracilis*.

In the second paper, Gregory and Holdsworth[3] reported the isolation from sow's milk of a protein which formed with cyanocobalamin a complex that did not stimulate the growth of *L. leichmannii*; after digestion with trypsin or papain some stimulation of growth occurred, and this was enhanced after the enzymic digest had been heated. Sow's milk not only contains vitamin B_{12} in bound form but also is capable of binding considerable amounts of added cyanocobalamin.

We have obtained evidence that some of the vitamin B_{12} in crude liver extracts cannot be assayed by means of the *E. coli* mutant, and have also observed binding of cyanocobalamin by crude liver extracts analogous to that recorded by Pitney *et al.* and Gregory and Holdsworth; but there are important differences in the nature of the complex formed. We have shown, for example (using for assay the *E. coli* mutant and not *L. leichmannii* or *E. gracilis*), that the apparent vitamin B_{12} content of these liver extracts increases on boiling and that only a proportion of added cyanocobalamin can be accounted for when using *E. coli* for assay. It was observed, however, that the 15-min. boiling found to be adequate by Pitney *et al.* was insufficient to liberate the bound vitamin in our liver extracts, heating for 4 hr. being optimal. Another striking difference between the behaviour of blood serum and liver extract towards vitamin B_{12} is that whereas Pitney *et al.* imply that liberation of vitamin B_{12} takes place as the result of denaturation of the protein to which it is bound, so that binding is presumably irreversible, we have found that when a crude liver extract is allowed to stand for some days after having been boiled, the apparent vitamin B_{12} content falls to the original value.

Our results suggest to us that crude liver extracts contain a vitamin B_{12}-binding substance, and that the vitamin B_{12} in such extracts is to some extent present in bound form, as has already been postulated by other workers[2,3]; but we believe that the binding is not due to the formation of a complex with a protein as has been suggested, although the possibility that vitamin B_{12} is bound to a peptide of low molecular weight cannot be excluded. We have found, for example, contrary to the observations of other workers[2,3] that the microbiological activity of our extracts is not increased by treatment with cyanide; secondly, that the bound vitamin B_{12} can be dialysed, although slowly, through a 'Cellophane' membrane; and thirdly, that the activity of the extracts is not increased by digestion with papain or trypsin, although pancreatin significantly enhances the activity.

We have also compared the behaviour of vitamin B_{12} in liver extracts with the behaviour of cyanocobalamin in presence of an intrinsic factor concentrate made from hog's stomach by the method of Prusoff *et al.*[5]. The two types of binding appear to be quite different. In the first place, there was no increase in activity as measured by *E. coli* after the solution had been boiled as occurred with liver extracts; and secondly, it has been reported that vitamin B_{12} is not dialysed through a 'Cellophane' membrane in presence of intrinsic factor, in contrast to the behaviour of the bound vitamin B_{12} in liver extracts.

Wijmenga *et al.*[5] have pointed out that no method of isolating cyanocobalamin from liver extracts has been described that does not involve a proteolytic step, and that when Smith[9,10] originally described the isolation of vitamin B_{12} he reported that two pink bands were formed on partition chromatography, one of which appeared to be transformed into the other on treatment with a proteolytic enzyme. Cooley *et al.*[6] have suggested that vitamin B_{12} may be present in liver in the form of a cobalichrome in which the cyano group is replaced by a protein or polypeptide moiety. That this may be partially true is suggested by the fact that we have invariably found less cyanocobalamin in liver extracts by the chemical method of Boxer and Rickards[11] than by microbiological assay, unless the liver extract has first been subjected to cyanide treatment, when the agreement between the two sets of results is fairly good. This confirms Boxer and Rickards's conclusion that "in liver concentrates, cyanocobalamin usually accounts for only a small fraction of total cobalamins".

By contrast, the cyano group is apparently unaffected when intrinsic factor is added to cyanocobalamin, since the results obtained with such a mixture by the method of Boxer and Rickards was in good agreement with the amount of cyanocobalamin present. This supports the observation of Wijmenga *et al.*[12], based on a study of absorption spectra, that the cyano group is still present in the cyanocobalamin-intrinsic factor complex.

A Riboflavin-producing Bacterium

RIBOFLAVIN synthesis has been demonstrated in a wide variety of micro-organisms by means of growth studies; these have been adequately reviewed from time to time[1]. Among the bacteria, members of various genera have been reported to produce riboflavin in very small amounts[2], and none has been reported which exceeds the capacity of *Cl. acetobutylicum* to produce this vitamin.

During the course of routine work, an air-contaminant was found to produce an intense greenish-yellow pigment in a medium consisting of casein hydrolysate and beef-extract. This pigment appears to be riboflavin; the compound, like the vitamin, has the following properties: (*a*) it exhibits an intense greenish-yellow fluorescence in ultra-violet light; (*b*) the fluorescence is instantaneously discharged on the addition of sodium hydrosulphite; (*c*) it has absorption maxima at 225, 269, 372 and 445 mμ, as measured in the Beckman spectrophotometer.

The air contaminant was found to be a bacterium. It was isolated in the pure state by the usual methods. On microscopic examination it was found to be coccoid, arranged in irregular groups of sizes 0·8–1·0 μ in diameter. It is Gram-negative (observed after 6 hr., 12 hr., 24 hr. and 48 hr.).

The amount of riboflavin produced by this organism was determined by carrying out static and agitated fermentations, using a medium containing casein hydrolysate and beef-extract. Riboflavin production was assayed by the fluorimetric method using a pure riboflavin solution as the standard and found to be of the order of 150–250 μgm./ml., the maximum amount being produced in the reciprocating shaker at 26° C., the yield obtained being 250 μgm./ml. This high yield of riboflavin by a bacterium is very interesting and further studies on the identification of the organism are in progress.

Acknowledgments are made to Dr. S. C. Roy, Dr. S. K. Bose and Mr. P. R. Pal, of the Department of Applied Chemistry, University of Calcutta, for their suggestions during the progress of the work.

Inhibition of D-Amino-acid Oxidase

PEPTIDES containing D-amino-acids are not attacked by D-amino-acid oxidase[1,2]. We have found that the action of pig kidney D-amino-acid oxidase on DL-leucine was inhibited by DL-leucinamide, DL-leucylglycine, DL-leucylglycylglycine, and by glycyl-DL-leucine. These compounds also inhibited the enzymic oxidation of DL-valine and DL-phenylalanine. Thus, DL-leucinamide when added to DL-leucine, DL-valine or DL-phenylalanine in a molar ratio 5 : 1 inhibited the oxidation by 35–45 per cent. DL-Leucylglycine inhibited the oxidation of DL-leucine by 40–45 per cent, of DL-phenylalanine by 50 per cent, and of DL-valine by 60 per cent. DL-Leucylglycylglycine inhibited the oxidation of DL-phenylalanine by 25 per cent, of DL-leucine by 30 per cent, and of DL-valine by 65 per cent. Glycyl-DL-leucine gave similar results. With glycylglycine no inhibition was obtained.

It was also found that derivatives of DL-valine, DL-leucine and DL-phenylalanine in which one of the amino-hydrogens was substituted by ethyl, hydroxyethyl or cyclohexyl radicals also acted as inhibitors of D-amino-acid oxidase. Thus, DL-N-ethylphenylalanine inhibited the oxidation of DL-phenylalanine by 70 per cent; DL-N-ethylleucine that of DL-leucine by 80 per cent; DL-N-hydroxyethylvaline that of DL-valine by 80 per cent; and DL-N-cyclohexylvaline that of DL-valine by 65 per cent. It was found in some cases that derivatives of one amino-acid inhibited the oxidation of other amino-acids more than that of the parent compound. For example, DL-N-ethylvaline inhibited the oxidation of DL-leucine by 45 per cent, whereas the oxidation of DL-valine was inhibited by 15 per cent only.

The oxidative deaminations of DL-valine, DL-leucine and DL-phenylalanine were also 23–30 per cent inhibited by DL-N-ethylleucylglycine.

The experiments were carried out in a Warburg apparatus at 38° by the usual technique. The *p*H varied between 8·1 and 8·5 (pyrophosphate buffer, 0·06 *M*). Aqueous extracts (usually 1 ml. per reaction mixture) of acetone-dried pig kidney preparations were used[1]. The final concentration of the DL-amino-acids was 0·008 *M* and that of the derivatives 0·04 *M*. The total volume of the reaction mixture was 2·5 ml. Oxygen uptake was measured after 60 min.

None of the amino-acid derivatives mentioned above was attacked by the enzyme to any significant extent.

It is known that the effects of crude enzyme preparations as used by us are the results of the combined activities of D-amino-acid oxidase proper and catalase[2]. The apparent inhibitions described above might therefore represent an increase in the rate of catalase action rather than an inhibition of the oxidase. We therefore tested the action of our enzyme extracts on hydrogen peroxide in separate experiments. The addition of either DL-N-ethylleucine, DL-leucinamide, DL-leucylglycylglycine or glycyl-DL-leucine had no influence on the catalase activity measured. Hence it may be concluded that the effects of the various compounds here described represent a true inhibition of D-amino-acid oxidase.

Hydrolysis of Methylglucosides

In the course of a study of the mechanisms involved in the solvolytic reactions of glycosides, we have investigated the position of bond fission occurring in the hydrolysis of α- and β-D-methylglucosides. The reactions were carried out in water enriched in oxygen-18, and the methanol produced was isolated by fractional distillation in an efficient column, and then pyrolysed to give carbon monoxide which was examined by a mass spectrometer. We have found that the hydrolysis of α- and β-D-methylglucosides both in 1 *N* acid solution and in the presence of appropriate methylglucosidases proceeds by fission of the hexose–oxygen bond:

$$R|\text{—O—CH}_3 + H_2{}^{18}O \rightarrow R\text{—}^{18}\text{O—H} + \text{HOCH}_3$$

The results of typical experiments are shown in Table 1.

Table 1

Substrate	Catalyst	*p*H	Temp. (° C.)	Time of heating (hr.)	% excess abundance oxygen-18 in solution	% excess abundance oxygen-18 in methanol
α-D-Methylglucoside	1 10 *N* HCl	—	80	65	0·540	0·006
"	Yeast* α-methylglucosidase	6·5	35·7	6	0·800	0·000
β-D-Methylglucoside	1 10 *N* HCl	—	80	65	0·540	0·008
"	Almond emulsin	4·6	35·7	24	0·360	0·029
Blanks Glucose + methyl alcohol	1 10 *N* HCl	—	80	65	0·540	0·001
"	Yeast α-methylglucosidase	6·5	35·7	6	0·800	0·003
"	Almond emulsin	4·5	35·7	30	1·63	0·005

* A solution containing yeast α-methylglucosidase was obtained by killing, after washing and pressing, brewer's bottom yeast with liquid nitrogen and extracting the resultant autolysate with 0·1 *N* ammonia. Extracts prepared by autolysing the cells with toluene or ethyl acetate gave similar results.

Armstrong's[1] classical demonstration that α-D-glucose could be detected in the products of enzymolysis of α-D-methylglucoside, and that similarly β-D-glucose could arise from β-D-methylglucoside, has been used for relating the configurations of the glucosides to those of the parent sugars. The implicit assumption is, as Koshland[2] has pointed out, that no Walden inversion occurs. The present results show that since it is the hexose–oxygen bond which breaks, Armstrong's results cannot safely be used in this way. It can be said, however, that given the configurations on other grounds, Armstrong's work shows that under his conditions substitution at the $C_{(1)}$ atom occurs without a Walden inversion.

It is interesting to note that, both in the acid- and the enzyme-catalysed reactions, the position of bond fission is the same. The acid-catalysed reactions presumably proceed via the reversible formation of the conjugate acids of the glucoside followed either by rate-determining formation of a carbonium ion, with or without ring opening, or alternatively by bimolecular attack on the $C_{(1)}$ atom of the pyranose ring by a water molecule. The latter possibility, which seems unlikely on steric grounds, would, of course, involve a Walden inversion at the $C_{(1)}$ atom; but owing to the rapid mutarotation of the product under acid conditions, this test has no diagnostic value.

We are grateful to Profs. E. D. Hughes and C. K. Ingold for their help and encouragement. We are also indebted to Messrs. Barclay Perkins, Ltd., for a generous gift of brewer's bottom yeast.

Effect of Oxygen on the Frequency of Chromosome Aberrations produced by 8-Ethoxycaffeine

SOME years ago, Thoday and Read[1,2] discovered that the frequency of chromosome aberrations produced by X-rays in root tips of *Vicia faba* is dependent on oxygen tension during irradiation, while that produced by α-rays is not. Since then this discovery has been confirmed by several investigations, and a similar effect of oxygen was found also, when other tissues and organisms were used as experimental material (for references, see Giles[3] or Gray[4]). In the case of X-rays, therefore, it seems to be a general rule that much less chromosome damage of the physiological, as well as of the structural, type is obtained when the irradiations are performed in the absence than in the presence of oxygen.

At present, the generally accepted explanation of the oxygen effect is "that oxygen makes available certain radicals produced from the decomposition of water which would otherwise be lost"[4]. Thus the effect of oxygen indicates that chemical steps intervene between ionization and chromosome damage. Since hydrogen peroxide is produced in water by irradiation only if oxygen is present in the case of X-rays, but independently of oxygen tension in the case of α-rays, Thoday and Read[2] assumed "that hydrogen peroxide had some influence on the process involved in chromosome structural damage". Facts in favour of the peroxide hypothesis have been presented also by Fabergé[5] and Giles[3]. Current opinion, however, favours the view that, in the case of X-rays at least, the major part in chromosome damage is played by the hydroperoxyl radical (HO_2).

With this radiochemical explanation of the oxygen effect in mind, it would not be expected that oxygen could have any influence on the frequency of chromosome aberrations produced by radiomimetic chemicals.

In connexion with a comparative study of the effect of X-rays and the purine derivative 8-ethoxycaffeine on root tip chromosomes of *Allium cepa*, the influence of oxygen tension was also tested. The radiomimetic effect of this and other purine derivatives as well as the methods used have been described previously[6,7].

The onions were placed on tubes with their roots immersed in saturated aqueous solutions of 8-ethoxycaffeine (10^{-2} *M*) through which nitrogen or oxygen was bubbled. In order to minimize the back diffusion of air, the bulbs as well as the upper parts of the tubes were enclosed in plastic bags with small openings for the egress of the gases. Before treatment, the 8-ethoxycaffeine solutions were saturated with oxygen or nitrogen. In the first experiment performed, four onions were treated with 8-ethoxycaffeine for 1 hr., two in nitrogen and two in oxygen, while two were used as controls. Before the 8-ethoxycaffeine treatments, the roots were pretreated in water for 30 min. with the gases in question, and after the treatment the onions were kept in oxygen or nitrogen for 15 min. before they were transferred for recovery to tubes containing tap-water. The two controls were treated in tap-water with oxygen and nitrogen respectively for 105 min. The temperature during treatment and recovery was 18° C. Fixations in alcohol–acetic acid (3 : 1) were made 3/4, 4, 8 and 24 hr. after the 8-ethoxycaffeine treatments. Slides were prepared as Feulgen squashes.

The examinations of the slides revealed that 8-ethoxycaffeine is much more effective in producing chromosome aberrations in oxygen than in nitrogen. As in the case of X-rays[2,3], both the stickiness effect and the frequency of structural chromosome changes were influenced by the oxygen concentration during treatment. The stickiness effect in oxygen was very strong and could be observed as long as four hours after treatment. After an ordinary treatment (in air), the stickiness effect usually disappears within two hours. In nitrogen only a very slight stickiness effect was produced. Fig. 1 shows how the structural chromosome changes produced by 8-ethoxycaffeine are influenced by the oxygen concentration. The effect is scored as abnormal anaphases, that is, anaphases with fragments and bridges. In each case the effect is estimated on the bases of at least 50, usually 100, analysed anaphases. Although the variation between the two bulbs treated in oxygen is very great, particularly in the 4- and 8-hr. fixations, there can be no doubt about the significance of the difference between the effects obtained in oxygen on one hand and those obtained in nitrogen on the other. Eight hours after the treatment, the frequency of chromosome aberrations produced by 8-ethoxycaffeine is at a maximum. At the same time the mean effect in oxygen is more than six times greater than that in nitrogen. The only effect found in the controls (oxygen or nitrogen alone) was a somewhat higher frequency of mitosis in the oxygen control.

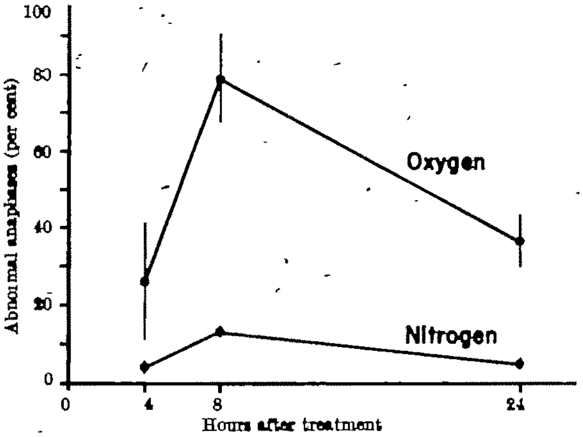

Fig. 1. Effect of 8-ethoxycaffeine in oxygen (upper curve) and in nitrogen (lower curve)

Because of the unexpected results obtained, the experiment was repeated. The experimental conditions were, however, altered in some respects. Thus the pretreatment with oxygen or nitrogen was reduced to 15 min., the 8-ethoxycaffeine treatment was reduced to 45 min., and the temperature during treatment and recovery was changed to 20° C. The results of this experiment were essentially the same as before: the effect produced by 8-ethoxycaffeine in oxygen was much greater than that in nitrogen. Thus the results indicate that the oxygen concentration influences the effect of 8-ethoxycaffeine on chromosomes similarly to the way in which it influences that of X-rays; the similarity seems, however, to be restricted to the production of chromosome aberrations. While the inhibition of mitosis by X-rays, according to Thoday and Read[2], is increased by oxygen, no such increase was observed in the case of 8-ethoxycaffeine.

Finally, it may be mentioned that, besides oxygen tension, the temperature during treatment also seems to influence the effect of X-rays and 8-ethoxycaffeine in a very similar way. Further, the cell is most sensitive to chromosome breakage by 8-ethoxycaffeine in the second half of interphase, as was found for X-rays by Revell[9], while the stage of greatest sensitivity to di (2 : 3-epoxypropyl) ether, and to other radiomimetic chemicals so far studied, lies in the first half of interphase[9,10].

A detailed account of these investigations will be published elsewhere.

A Second Virus Disease of the Leatherjacket, *Tipula paludosa*

IN an earlier communication[1], a 'polyhedrosis' of apparently cancerous blood cells of *Tipula paludosa* larvæ was described. The cytoplasmic disease described here is primarily of the larval fat body. No multiplication of the fat cells is involved, and no inclusion bodies are formed as the result of the disease. A few animals with both diseases have been observed in addition to the many in which they occurred singly.

The intact infected animal may be recognized in strong sunlight, when the fat body appears purple through the wetted skin. In the course of the disease the lobules of the fat body distend enormously and the tissue becomes nodular. The nodules are orange in transmitted light and iridescent, purple, blue, green, etc., in reflected light. The animals, when moribund, become purplish-white in colour with the disruption of diseased fat cells and the liberation of their contents into the blood. Death occurs two to four weeks or more after the disease becomes detectable. As many as 15 per cent of a low-density natural population of *Tipula* larvæ were found to have the disease, which appears to be less virulent than the polyhedroses of lepidopterous larvæ.

The cytology of infected cells has been examined in whole mounts of fat tissue, both unfixed and fixed in osmic acid, alcohol and Carnoy's fluid, and in sections fixed in the last. Early in the course of the disease the cells lose their fat globules. While the infected cells are still only slightly enlarged, highly refractile cytoplasmic networks form which usually completely surround their nuclei. At this stage one or several small spots, orange in transmitted light, become visible in the cytoplasm. The fat body then becomes nodular owing to the enormous enlargement of the infected cells, the cytoplasms of which outside the networks, which are now also enlarged, become completely filled with this material, orange in transmitted light and iridescent in reflected light (Fig. 1). The iridescence is readily visible even in 4-μ sections of fixed tissue.

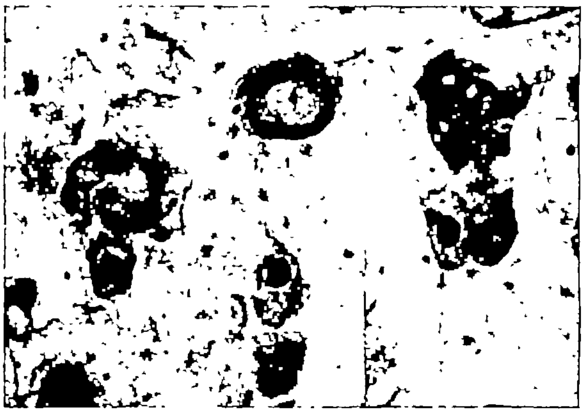

Fig. 1. Section of fat body cells of diseased larvæ of *Tipula paludosa* showing 'normal' nuclei, enlarged cytoplasm, and the peculiar cytoplasmic nets × 900

The cytoplasmic nets of the infected cells are heavily loaded with ribose nucleic acid, and after acid hydrolysis lose their capacity to stain intensely with Giemsa fluid. They are Feulgen-negative. The cytoplasm of these cells stains only a pale blue wash with Giemsa; but after acid hydrolysis it stains an intense purple-red colour. It is intensely Feulgen-positive throughout. Sections, 4 μ or more in thickness, of Carnoy-fixed nodules swell markedly in glacial formic acid and in 1 *N* sodium hydroxide, and shrink again in water, properties which are shared by the untreated Feulgen-positive 'polyhedra' described previously[1]. The homogeneous unfixed cytoplasm swells in water and dilute alkalis and proceeds to break down to minute granules at the limits of visibility. By high-speed differential centrifugation of infected fat bodies disrupted and washed in water or 0·14 *M* sodium chloride, pellets of particles 100 mμ diameter may be obtained. These pellets are orange in transmitted light and iridescent in reflected light. After hydrolysis for 1 hr. in 1 *N* hydrochloric acid at 100° C., this material has a typical nucleic acid absorption spectrum with its peak at about 265 A.

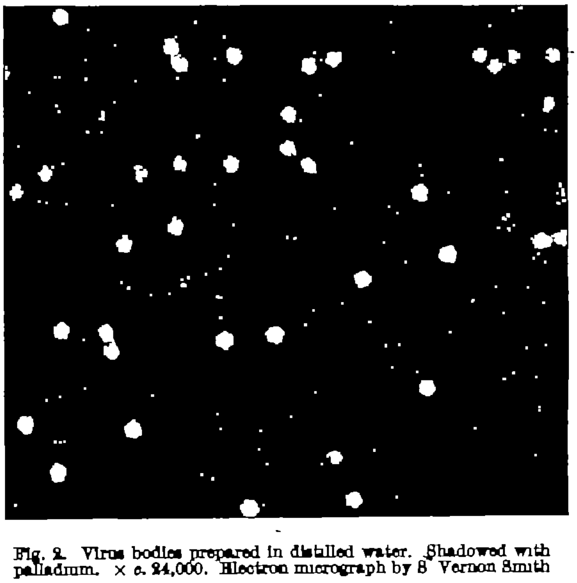

Fig. 2. Virus bodies prepared in distilled water. Shadowed with palladium. × *c.* 24,000. Electron micrograph by S. Vernon Smith

The evidence indicates that the particles contain deoxyribose nucleic acid. It is concluded that the 100-mμ particles (Fig. 2), with which the iridescence of the cytoplasm is associated, are the virus. The virus bodies are not simple spheres, but are somewhat irregular in shape and composite, many smaller particles being embedded in each. They thus resemble the viruses of the cytoplasmic polyhedroses of the midgut of lepidopterous larvæ[1,2], rather than the rod-shaped viruses of the nuclear polyhedroses.

Factors affecting the Larval Spot Colours of the Emperor Moth, *Saturnia pavonia* L.

FROM time to time the variation in the colour of the spots of the larvæ of *Saturnia pavonia* has attracted attention. These spot colours do not develop until the fourth and fifth instars. The spots of any given larva are similarly coloured; but the colour itself may vary within the range of pale lemon-yellow through orange to pink. From the selective breeding experiments of Poulton[1], it was apparent that the colour differences between larvæ could not be attributed to a simple genetical basis.

I have observed that the spot colour of the individual larva changes progressively throughout the duration of the instar, being pale lemon-yellow immediately after the moult and generally orange or pink by the time of the next moult or ensuing pupation. This progressive colour change has been found not to be simply dependent on the larval age within the instar but to be primarily a response to the intensity of the light to which the larva is exposed throughout the instar, the spots of larvæ which are kept in the dark remaining yellow. With larvæ exposed to light the rate of the colour change is most rapid in the few hours immediately following the moult. Larvæ which have been kept in the dark for the first three days after the moult show little colour change when exposed to normal daylight for the remainder of the instar. The final spot colour of the fourth instar does not appear to influence the spot colour of the fifth instar.

Experiments have been carried out and are continuing on the relationship between the rate of response and the light intensity in order to determine the nature of the response and to ascertain if it depends on a trigger-type reaction. The response appears to be locally determined and is not dependent on light entering the ocelli. The actual colour change itself involves two major components, the change from yellow to orange occurring in the underlying epidermal cells while changes from yellow through orange to pink occur in the overlying cuticle.

Fuller details will be published later.

Identity of *Gammarus tigrinus* Sexton 1939

Gammarus tigrinus Sexton[1] was described from saline waters in the Avon area, and has since been recorded from fresh and saline waters in several places in England and Ireland[2,3]. A map showing the known localities will appear in volume 12 of the *Proceedings* of the International Association of Theoretical and Applied Limnology.

Because it is unknown from other parts of Europe, and is closely related to the North American species *G. annulatus* Smith, Spooner[3] has suggested that it is probably a recent introduction from the New World. At the suggestion of Dr. S. G. Segerstråle, of Helsinki, I asked Dr. E. L. Bousfield, of the National Museum of Canada, if he could assist me in identifying the species. He informed me that he had long been of the opinion that it was the common North American freshwater and oligohalme brackish species *G. fasciatus* Say, which it resembles in being distinctly striped when alive—a character not shown by the brackish-water species *G. annulatus*. Comparison between specimens of *G. fasciatus* kindly sent to me by Dr. Bousfield and British specimens of *G. tigrinus* has fully confirmed this belief. The name *G. tigrinus* must therefore be superseded by *G. fasciatus*.

This species occurs widely in eastern North America, and is common in weedy places (Clemens[4]). In Great Britain it is also found in weedy places on muddy substrata, a type of habitat not favoured by any of the native species, although often colonized here by *Crangonyx gracilis* Smith, which is also of North American origin. In view of this, and of the importance of amphipods as food for fishes, *G. fasciatus* may well prove to be a useful animal for introduction into fish-ponds. At Wyken Slough, near Coventry, a muddy weedy lake, it would appear to be the main food organism for a large and varied population of coarse fishes.

The Maximum of the Planck Energy Spectrum

THE spectral distribution of energy radiated from a black body is well known to exhibit a maximum. For example, the thermal radiation from a 6,000-deg. black body (to which the sun approximates) is chiefly concentrated towards the visible wave-lengths and falls off in the infra-red and ultra-violet.

It is natural to inquire where this maximum falls, and Wien's law is usually called on to supply the answer. This law is often quoted in the form:

$$\lambda_m T = 0 \cdot 2897 \text{ cm. deg.},$$

where λ_m is the wave-length where the maximum falls and T is the temperature of the black body. (Numerical values are based on the following values of fundamental constants: $h = 6 \cdot 623 \times 10^{-27}$, $c = 2 \cdot 99772 \times 10^{10}$, $k = 1 \cdot 3803 \times 10^{-16}$.) Thus, at 6,000 deg. the formula gives $\lambda_m = 4{,}829$ angstroms, which is towards the middle of the visible spectrum.

The derivation of the formula reminds us that the spectral concentration of energy is measured by the amount lying between wave-lengths λ and λ + dλ. But one might adopt the equally valid interval between frequencies f and $f + df$, which is in fact more appropriate for certain kinds of apparatus. Although it is not well known that this would make a difference, the formula changes to

$$\lambda_m T = 0\cdot5098 \text{ cm. deg.},$$

the constant being increased by a factor 1·76. This substantial change moves the maximum for a 6,000-deg. body to 8,497 angstroms.

This is an infra-red wave-length not visible to the human eye. As the calculation is quite as valid as the one familiar in text-books, it runs counter to the widespread impression that the energy spectrum of sunlight has its maximum in the spectral band visible to the human eye.

This is one point of interest. If we return to the inquiry about the location of the maximum of the black-body energy spectrum, it must be concluded that Wien's law does not give a unique answer. The line of reasoning on which it is based leads to two different answers, according as one measures the radiation per unit of frequency or per unit of wave-length. This suggests that Planck's formula be re-examined for any further maximal properties, especially any which are invariant with change from a wave-length to a frequency basis.

Let $\Lambda = \log \lambda$ and consider the energy $E_\Lambda d\Lambda$ lying between Λ and $\Lambda + d\Lambda$. Let its maximum fall at $\Lambda_m = \log \lambda_0$. Consider also the energy between F and $F + dF$ where $F = \log f$. In this case the maximum clearly falls at the same wave-length λ_0 as in the first case. The reason is that dF and $d\Lambda$ represent fractional increments of f and λ, and thus maintain their ratio constant throughout the spectrum. Previously, when spectral intervals were measured in units of frequency or wave-length, the relative sizes of the two measures varied with frequency so that maximum energy per unit frequency interval was not a maximum per unit wave-length interval, and vice versa.

Now if one considers any function L, more general than *log*, and regards it in turn as a function of λ and then of f, the energy lying between L and $L + dL$ will in general not exhibit a maximum at the same wave-length in the two cases. But if it does, the wave-length is found to be λ_0 as before. In order that L should lead to a single maximum, it is necessary that $dL/d\Lambda = 0$ when $\Lambda = \Lambda_m$.

The maximum at λ_0 is thus unique in being free from the objection of altering when a change is made from a wave-length to a frequency basis. It falls where the energy per octave (or similar logarithmic interval) is a maximum. It may be located by differentiating Planck's formula with respect to the logarithm of either the frequency or the wave-length. A Wien-type law continues to hold for the maximum so defined, but in the form

$$\lambda_m T = 0\cdot3669 \text{ cm. deg.}$$

(This constant comes from the root of the equation $\exp. (-x) + \frac{1}{4}x - 1 = 0$, where $x = hc/k\lambda T$.)

The location of this natural maximum of the 6,000-deg. spectrum proves to be 6,115 angstroms, at the red end of the visible spectrum.

Measurements of Lifetimes of Excited States of Atoms by the Method of Delayed Coincidences

WE have adapted the method of delayed coincidences[1] to the investigation of lifetimes of excited states of atomic helium. Helium gas at a pressure of about 0·01 mm. mercury was excited by a beam of 40 eV. electrons, and the photons emitted in the subsequent de-excitation detected by means of an *E.M.I. VX* 5031 photo-multiplier, the wave-lengths corresponding to the various transitions being selected by means of Barr and Stroud interference filters. The intensity of the electron beam was modulated by means of a grid which was maintained at a potential sufficiently negative to cut off the beam completely except during the application of a positive voltage pulse of duration 2×10^{-8} sec. and repetition rate 10 kc./s. The helium atoms were therefore excited by short bursts of electrons. The voltage pulses from the photomultiplier, corresponding to the ejection of single electrons from its cathode, were amplified and applied to one side of a coincidence unit of resolving time 2×10^{-8} sec. The pulse used for modulating the electron beam was also applied to the other side of the coincidence unit through a variable length of 'Uniradio 57' cable. A coincidence was therefore registered only if the delay in this cable was equal to the interval between the electron burst and the subsequent emission of a photon, and for delays longer than the overall resolving time of the apparatus the variation of coincidence-rate with delay should show an exponential decrease, the decay constant being the reciprocal of the mean life of the excited state involved. We are satisfied that for the transitions referred to below, the conditions of our experiment are such that the effects on the apparent lifetime of recombination of ions and of cascade transitions from higher states are negligible.

It is desirable to test the performance of an apparatus of this sort by examining a transition the lifetime of which is believed to be much shorter than the resolving time of the apparatus, so giving what is usually called a 'prompt' curve. We have endeavoured to use for this purpose the 5016 A. line emitted in the transition $3\,^1P \rightarrow 2\,^1S$. The $3\,^1P$ level is expected to have a very short lifetime because it can also decay to the ground state with the emission of a quantum of wave-length 537 A., and this latter transition should be very fast because of the λ^{-3} factor in the theoretical expression for the transition probability. Theoretical calculations indicate that the mean life of the $3\,^1P$ level is about 2×10^{-9} sec. Results obtained with the 5016 A. line are represented by the two lower curves in Fig. 1, which shows the coincidence-rate plotted logarithmically as a function of the delay for pressures of 0·005 and 0·03 mm. mercury. For delays greater than $1\cdot5 \times 10^{-7}$ sec. the curves are linear, showing that the decay is exponential. The fact that the curves do not rise until the delay is 9×10^{-8} sec. is due to the transit time of the electrons in the photomultiplier.

The curve obtained at 0·005 mm. is appreciably narrower than that at 0·03 mm.; but even the former is significantly wider than is to be expected for a truly prompt transition, indicating that the apparent lifetime of the transition is greater than 10^{-8} sec. We believe that the reason for this increase in the apparent lifetime of the $3\,^1P$ level and its dependence on pressure lies in the phenomenon of imprisonment

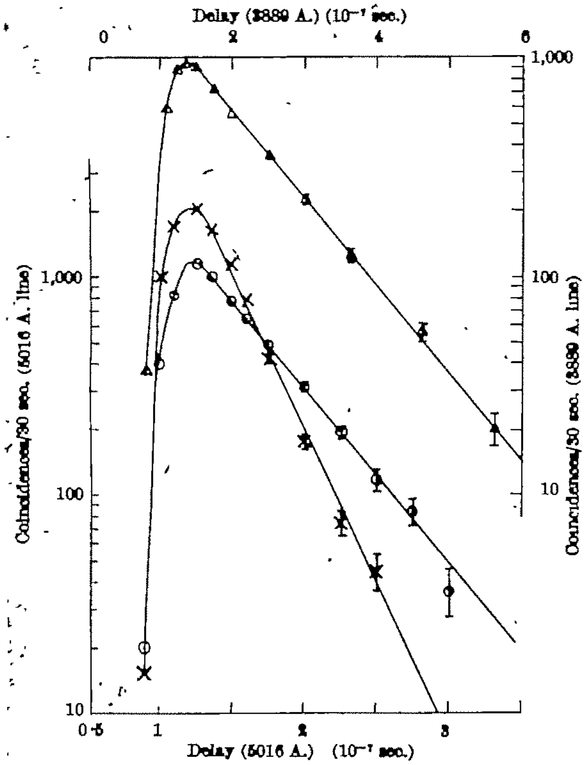

Fig. 1. ○—○—, 5016 A., p = 0·03 mm. mercury; ×—×—, 5016 A., p = 0·005 mm. mercury; △—△—, 3889 A., p = 0·03 mm. mercury

of resonance radiation[2]. Because the 537 A. line is a resonance line, the time which atoms spend in the $3\,^1P$ level is considerably lengthened, and this is accompanied by an increase in the apparent lifetime of the $3\,^1P \rightarrow 2\,^1S$ transition. The linear portions of the curves correspond to exponential decays with mean lives of $2{\cdot}9 \times 10^{-8}$ and $5{\cdot}3 \times 10^{-8}$ sec., which agree well with the values calculated from Holstein's theory[3] of the imprisonment process for pressures of 0·005 and 0·03 mm. mercury respectively when allowance is made for the effect of the $3\,^1P \rightarrow 2\,^1S$ transition. We were unable to work at pressures lower than 0·005 mm. because, as was pointed out by Skinner and Lees[4], one consequence of the imprisonment process is that the intensity of the 5016 A. line is not proportional to pressure. At pressures low enough to make the apparent lifetime approach the natural lifetime, the intensity is so low as to be unusable with our present apparatus. For this reason we have been unable to obtain a truly prompt curve, but we are considering alternative ways of doing so.

As a transition the lifetime of which is expected to be long we have chosen the 3889 A. line emitted in the transition $3\,^3P \rightarrow 2\,^3S$. This would be expected to have a longer lifetime than the corresponding singlet transition because the $3\,^3P$ levels cannot decay to the ground-state. Results obtained with the 3889 A. line are represented by the top curve in Fig. 1. The shape of this curve was found to be independent of pressure, which is to be expected since triplet lines cannot be imprisoned. From the slope of the linear portion of this curve we estimate the mean life of the $3\,^3P$ triplet to be $(1{\cdot}08 \pm 0{\cdot}07) \times 10^{-7}$ sec.

Measurements of this sort are of interest because for light atoms lifetimes of states can be computed quantum-mechanically with moderate accuracy, so that a check on radiation theory is possible. Calculations of transition probabilities for helium have been made by Hylleraas[5], Goldberg[6] and Bates and Damgaard[7]. Taking the total decay constant of the $3\,^3P$ triplet to be the sum of the transition probabilities for the $3\,^3P \rightarrow 2\,^3S$ and $3\,^3P \rightarrow 3\,^3S$ transitions, we obtain the following values for the mean life τ:

	Hylleraas	Goldberg	Bates and Damgaard
$\tau \times 10^7$ sec.	1·18	0·83	0·97

Too much weight should not be attached to the results of Goldberg because he uses rather inexact wave-functions. Our experimental value is almost exactly the mean of the other two values; but this result is perhaps somewhat fortuitous in view of the uncertain accuracy of the theoretical calculations.

A full account of this work will be published elsewhere.

Random Fragmentation

The problem of random fragmentation of a line into a finite number of N parts has received considerable attention, partly because of its application in assessing the randomness of radioactive disintegrations and cosmic ray events. For a line of length l the average number of fragments equal to or greater than x is[1]:

$$N(x) = N(1 - x/l)^{N-1}. \qquad (1)$$

This equation is readily applied to discuss[2] an idealized case of random fragmentation of area. Consider a rectangle of sides l_1 and l_2 (area $\Sigma = l_1 l_2$) and imagine it to be divided into subrectangles by drawing at random N_1 and N_2 lines respectively parallel to the two sides of the rectangle. If $N(S)$ be the average number of elements of area equal to or exceeding S, we have, using equation (1):

$$N(S) = \frac{N_1 N_2 (N_1 - 1)\,(N_2 - 1)}{l_1 l_2} \iint\limits_{xy > S} \left(1 - \frac{x}{l_1}\right)^{N_1 - 2} \left(1 - \frac{y}{l_2}\right)^{N_2 - 2} dx\,dy$$

$$\sim -\,2N_0 \left(\frac{S}{S_0}\right)^{1/2} K_1 \left[2\left(\frac{S}{S_0}\right)^{1/2}\right], \qquad (2)$$

where $K_1(z)$ is the usual Bessel function of imaginary argument, $N_0 = N_1 N_2$ is the total number of elements and S_0 the average area of an element,

$$S_0 = \Sigma / N_0.$$

For $S \gg S_0$ we obtain the approximate relation:

$$N(S) \sim \pi^{1/2} N_0 \left(\frac{S}{S_0}\right)^{1/4} \exp\left\{-\,2\,(S/S_0)^{1/2}\right\}. \qquad (3)$$

As already remarked, equation (2) has been obtained for an idealized case. It may not be unreasonable to expect that it would describe the essential features of the observed fragmentation of plates, for example. We have found it to be the case for the fragmentation of glass plates; details will be published elsewhere.

It is an obvious step to extend the foregoing treatment to the case of random fragmentation of volume. Taking as before an idealized case of the random subdivision of a rectangular parallelepiped of volume Ω, we obtain, using equation (1), for the number of elements with volume equal to or greater than V,

$$N(V) \sim \frac{2\pi}{3^{1/2}} N_0 \left(\frac{V}{V_0}\right)^{1/3} \exp\left\{-3\,(V/V_0)^{1/3}\right\}, \qquad (4)$$

where N_0 is the total number of fragments and V_0 the average volume of a fragment ($V_0 = \Omega/N_0$): this means that log $N(V)$ and $V^{1/3}$ follow a nearly linear relation. If V_1 denotes the volume of the largest element, we have from equation (4), by putting $N(V) = 1$:

$$\left(\frac{V_1}{V_0}\right)^{1/3} = \frac{1}{3}\log\left(\frac{2\pi N_0}{3^{1/2}}\right) + \frac{1}{9}\log\,(V_1/V_0). \qquad (5)$$

It is of interest to consider the application of (4) to the cosmological problem of the mass-distribution of stars in the galaxy. A similar consideration should apply, and possibly even more plausibly, to the problem of the mass-distribution of galaxies. Fig. 1, in which the values given are based on the data (pp. 334, 367) taken from Baker, R. H., "Astronomy" (D. Van Nostrand Co., New York, 1950), is a plot of log $N(M)$ against $M^{1/3}$ (M is in units of the solar mass) where $N(M)$ is the (relative) number of stars of mass equal to or exceeding M. What is directly known from observation is the distribution of stars according to their intrinsic luminosity—the luminosity function. The use of the observed mass–luminosity relation gives the distribution of stars according to mass, that is, $N(M)$ as a function of M. It will be observed that the points (log $N(M)$, $M^{1/3}$) lie almost on a straight line. This makes it likely, as is envisaged in some current cosmological theories, that stars have been formed as a result of some sort of a random fragmentation of dense pre-stellar matter (at an epoch about 3 × 10^9 years ago). The process can be conceived as equivalent to fragmentation of volume, because at the epoch of fragmentation the material could be regarded as of almost uniform density (of the order of nuclear density of matter). It is indeed remarkable that the distribution law (4) accords as well as it does with the observed distribution of stars in the Milky Way. A more detailed account of this investigation will appear in the *Proceedings of the National Institute of Sciences, India*.

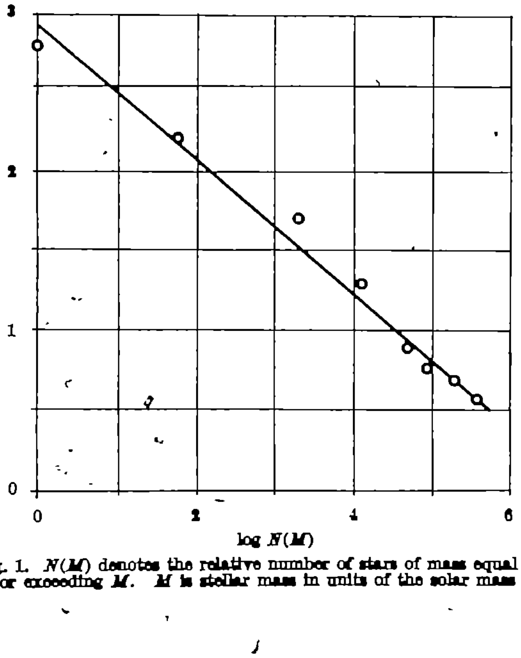

Fig. 1. $N(M)$ denotes the relative number of stars of mass equal to or exceeding M. M is stellar mass in units of the solar mass

Thermoelectric Power and the Bauschinger Effect

It has been proposed[1,2] that the Bauschinger effect which occurs in face-centred cubic metals after a plastic strain exceeding 1 per cent might be attributed to the rearrangement of dislocations at the beginning of the reversal of strain. If we rather crudely reckon that changes of thermoelectric power and electric resistance are measures of the total disorder in a lattice, then these should remain constant during the Bauschinger strain, though increasing during previous and subsequent plastic strain, because during the Bauschinger strain the total disorder in the lattice is not increasing, but merely being re-arranged.

Preliminary measurements of the thermoelectric power of copper now support this view. We have measured the thermoelectric power of 99·9 per cent copper as a function of plastic shear strain, using torsion and reverse torsion of a thin-walled tube. The change of thermoelectric power during a unidirectional plastic shear strain of 1 per cent is very small, and the change during the Bauschinger strain is even smaller, so that even when all precautions are taken the overall accuracy is not as high as might be desired. In our experiments the ends of the specimen are maintained at 10° and 30° C. respectively, and the thermal e.m.f. is measured to an accuracy of 5 × 10^{-11} V./deg. C. by a null method using a Paschen galvanometer as detector.

Six tests were carried out. Each specimen was first deformed by the application of a stress $+\sigma_0$, then unloaded, and a negative stress applied in suitable increments until it exceeded $-\sigma_0$. In these tests the stress σ_0 had values between 550 kgm./cm.^{2} and 1,100 kgm./cm.^{2}, corresponding to strains between 10 and 30 per cent. In each test the mean rate of increase of thermoelectric power with plastic shear strain during the Bauschinger strain (that is, between $+\sigma_0$ and $-\sigma_0$) was compared with the mean rate of increase after $-\sigma_0$ was passed, and their ratio determined. This ratio is found to lie within the range 29 ± 21 per cent. We therefore conclude that during the Bauschinger strain the increase of disorder in the lattice is decidedly smaller than during ordinary unidirectional plastic strain.

It may be argued that though the Bauschinger strain is attributed to the rearrangement of dislocations, changes in thermoelectric power are more probably due to changes in the number of vacancies and interstitial atoms present, as suggested by Seitz[3] for the case of electric resistance. This difference is of no significance if we assume that vacancies and interstitial atoms are formed as a result of the intersection of screw dislocations; during the Bauschinger strain the dislocations are regarded as each moving a distance equal to their mean distance apart[1], so that to a first approximation no dislocations cross each other, and relatively few vacancies or interstitial atoms are generated.

Simplified Particle-size Calculations

PARTICLE-SIZE analysis by microscopical methods provides large samples of measurements which then need numerical analysis to give estimates of average diameters, specific surface, etc. When, as is often the case, particle sizes are log-normally distributed[1–4], tedious summation of powers of the sizes can be avoided if the cumulative distribution is plotted on log-probability paper[1,4]. From this, estimates of the mean, $\bar{y}$, and standard deviation, σ, of the distribution of log sizes can be read off; from these two values can be calculated any of the many kinds of average which are used in this work. If D be such an average, the general equation for this purpose is:

$$\log D = \bar{y} + c\,\sigma^2, \tag{1}$$

where the value of c depends only on the kind of average, D, that is being calculated[1,4].

Even this calculation can be avoided, and a simple completely graphical method substituted with little loss of precision.

If we regard the (linear) abscissa scale (see Fig. 1) as the normal deviate z with origin at the 50 per cent point, the line drawn on probability paper has the equation:

$$Y = \bar{y} + \sigma z. \tag{2}$$

If one unit of y (between particle sizes of 1 and 10, or 10 and 100) occupies a distance A on the paper and one unit of z a distance B (the distance between the 0·1 per cent and 99·9 per cent abscissæ is $6{\cdot}2B$), equation (2) becomes:

$$Y = \bar{Y} + \frac{A}{B}\,\sigma Z, \tag{3}$$

where Y, Z are co-ordinates in units of distance and $\bar{Y}$ is then the ordinate corresponding to $\bar{y}$.

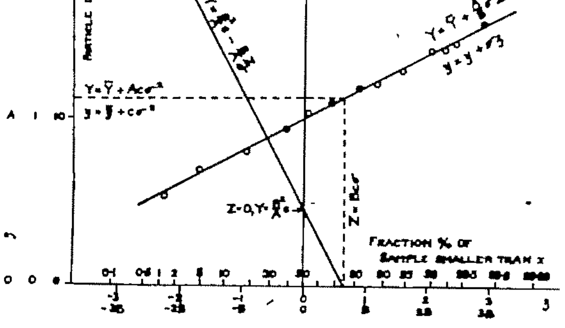

Fig. 1. Graphical method using logarithmic probability paper

The line through the point $Z = 0$, $Y = \frac{B^2}{A}c$ ($z = 0$, $y = \frac{B^2}{A^2}c$) normal to (3) will be:

$$Y = \frac{B^2}{A}c - \frac{B}{A}\frac{Z}{\sigma}, \tag{4}$$

and will meet the Z-axis at $Z = Bc\,\sigma$.

The ordinate of (3) corresponding to this value of Z, namely,

$$Y = \bar{Y} + Ac\,\sigma^2,$$

is equivalent to: $y = \bar{y} + c\,\sigma^2 = \log D$, and gives the average that is sought.

The scale-factors A, B are constant for any one kind of probability paper, and c depends only on the average diameter being estimated. Hence the point $Z = 0$, $Y = \frac{B^2}{A}c$ is independent of the sample of sizes and can be determined beforehand for each average diameter.

There are occasions also when very approximate results will suffice and are needed rapidly; the number of particles measured and the calculation can then both be greatly reduced. It is necessary only to pick out and measure the largest particle and the smallest particle of the sample and to make a rough estimate of the total number, n, of particles that could have been measured.

If y_1, y_n are the logarithms of the largest and smallest particle sizes, their mid-range $\frac{1}{2}(y_1 + y_n)$ provides an estimate of the mean $\bar{y}$, and from the range the standard deviation σ can be estimated as $\frac{1}{w}(y_1 - y_n)$, where w is roughly the expected range in samples of n. The value of w depends on n and can be chosen from the following table, which is based on Tippett's table[5] and is sufficient for this approximate method.

n	w
20–35	4
35–70	4½
70–140	5
140–300	5½
300–700	6
700–1,700	6½
1,700–3,000	7

It must be borne in mind not only that this method is approximate and not efficient but that, as in all cases where range and mid-range are used as estimators, the results can be affected, without it being known, either by truncation of the sample or by the presence in the sample of exceptionally large or small particles which do not belong to the population of particles under consideration. Thus it is recommended that this method is best used as a rough check on calculations by some longer method, or for obtaining quickly approximate information from a sample of a material about which something is already known, so that an unexpectedly large or small estimate of σ can be recognized and regarded with suspicion.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Tuesday, September 21—Friday, September 24

Institution of Naval Architects (at the Electric Hall, Torquay)—Annual Meeting.

Wednesday, September 22—Friday, September 24

National Smoke Abatement Society (at Scarborough).—Twenty-first Annual Conference.

Thursday, September 23

Oil and Colour Chemists' Association (in the Chemistry Theatre, University College, Gower Street, London, W.C.1), at 10.30 a.m.—Symposium on "Rheology and Settlement of Pigmented Systems".

Friday, September 24

Biochemical Society (in the Department of Biochemistry, The University, Sheffield 10), at 11 a.m.—Scientific Papers

Physical Society (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Sir Geoffrey Taylor, F.R.S.: "Diffusion and Mass Transport in Tubes" (38th Guthrie Lecture).*

Friday, September 24—Saturday, September 25

Society of Leather Trades' Chemists (in the large Chemistry Lecture Theatre, The University, Leeds)—Annual Conference.

Friday, September 24

At 2 p.m.—Prof. J. T. Randall, F.R.S.: "Observations on the Collagen System" (Sixth Procter Memorial Lecture).

Friday, September 24—Monday, September 27

Aslib (at Church House, Westminster, London, S.W.1)—Annual Conference

---

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chemists (with honours degree in chemistry or chemical engineering or A.R.I.C. or A.M.I.Chem.E.), to carry out work on the supply of potable water, disposal of radioactive solid and liquid waste, control of pickling and plating shops and other industrial chemical processes—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berkshire, quoting 2/103/140 (September 24).

Demonstrator in Chemistry and Biology—The Registrar, The Technical College, Sunderland, Co. Durham (September 25).

Physicist (with good honours degree in physics and at least two years research experience, and preferably with some practical acquaintance with electronics) for work in the field of psycho- and physioacoustics—The Secretary, Institute of Laryngology and Otology, 330–332 Gray's Inn Road, London, W.C.1 (September 25).

Experimental Officer (with university degree in an approved scientific subject, or equivalent qualifications, and preferably with qualifications or experience in library and information work and a knowledge of foreign languages) in the Scientific Development and Forensic Science Department, Ministry of Commerce—The Secretary, Civil Service Commission, Stormont, Belfast (September 27).

Scientific Officer (with an honours degree in chemistry and postgraduate experience in agricultural chemistry, or an honours degree in agricultural chemistry) in the Chemical Research Division, Ministry of Agriculture, for research work and possibly for teaching duties in the Faculty of Agriculture, Queen's University, Belfast—The Secretary, Civil Service Commission, Stormont, Belfast (September 27).

Principal Assistant Engineer (with honours degree or Corporate Membership of the I.Mech.E., or I.E.E., and with sound knowledge of power station design) in the Station Development Sub-Branch, for work in connexion with the siting, planning and negotiation of facilities and consents for new and extended power stations—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting T/518 (September 28)

Senior Lecturer (with high academic and research qualifications, and ability to teach to special (honours) degree standard) in Organic Chemistry—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (September 28).

Advisory Officer (with high scientific qualifications and considerable postgraduate experience in animal husbandry) in Animal Husbandry, to assist the advisory services with animal husbandry problems and to carry out investigational work arising therefrom—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (September 30).

Lecturer or Assistant Lecturer (with honours degree in physical oceanography, mathematics or physics, and prepared to spend several weeks each year at sea) in the Department of Oceanography—The Registrar, The University, Liverpool (September 30).

Research Assistant (graduate in science (biochemistry)) for work on the metabolism of vitamin C in relation to rheumatic disease—The Secretary, Rheumatic Unit, Northern General Hospital, Ferry Road, Edinburgh (September 30).

Lecturer (with good honours degree in electrical engineering and should preferably have completed a graduate apprenticeship) in Electrical Engineering—Head of the Electrical Engineering Department, City and Guilds College, London, S.W.7 (October 1).

Assistant Metallurgist with knowledge of copper and its alloys, and preferably with the ability to write on technical matters—The Secretary, Copper Development Association, Kendals Hall, Radlett, Herts.

Assistant Surveyors (with experience in carrying out topographical surveys by plane table and tacheometer) in the Government of Kenya Agricultural Department—Crown Agents, 4 Millbank, London, S.W.1, quoting M2B/40428/TA.

Chemists (science graduates, with first- or second-class honours degrees) in the London Transport Central Laboratory, Chiswick, for work on the development of tests for lubricants and investigations on the performance of lubricants under service conditions—Staff Officer, London Transport, 55 Broadway, London, S.W.1, quoting F/HV538.

Engineering Surveyor (with experience in the use of the level, theodolite, tacheometer and plane table sufficient to carry out surveys for engineering projects) with the Government of Tanganyika—Crown Agents, 4 Millbank, London, S.W.1, quoting M2B/30471/TA.

Head (with teaching, industrial or research experience) of the Chemistry and Applied Chemistry Department—The Principal, Royal Technical College, Salford 5.

Heads (with honours degree in chemistry, metallurgy, physics or engineering, or equivalent qualifications, with experience in the control and administration of applied research, and preferably with experience of the techniques and precautions involved in the handling of highly toxic and radioactive materials) of Laboratories of the United Kingdom Atomic Energy Authority, for duties including the administration and management of the laboratories, the direction of the scientific work and liaison with the operations and design groups—United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 666.

Lecturers and Assistant Lecturers in Physics, Mineralogy, Chemical, Electrical, Mechanical and Mining Engineering, at the University of Indonesia—The Cultural Attaché, Indonesian Embassy, 38 Grosvenor Square, London, W.1

Organic Chemist for the National Coal Board, North-Eastern Section, for work on the investigation of problems connected with by-products from coke oven plants—Divisional Chief Scientist, Roundwood Colliery, Parkgate, Rotherham, Yorkshire.

Physicist (with a degree in physics and the ability of applying experimental techniques to the solution of fluid problems in the iron and steel industry) in the Fluid Dynamics Section of the Physics Department—Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Principal Scientific Officers or Senior Scientific Officers (with first- or second-class honours degree in physics and with some years postgraduate research experience in mass spectrometry or nuclear physics), to undertake research and development work—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 280/WGE/2.

Research Assistant (with qualifications in mathematics or physics and preferably with experience of either X-ray crystallography or large-scale computing) in the Department of Inorganic and Structural Chemistry, for work on the preparation and carrying out of programmes on crystallographic calculations—Prof. E. G. Cox, Department of Inorganic and Structural Chemistry, The University, Leeds 2.

Research Assistant in the Department of Physics, for work on an X-ray investigation of ternary alloy systems with adamantine structure—The Registrar, The University, Nottingham.

Research Entomologist (with an honours degree in biology and with at least two years postgraduate training in scientific research specialising in entomology, and preferably with statistical training or interest in statistics) in the West African Institute for Trypanosomiasis, to undertake research upon the behaviour, breeding and longevity of the tsetse fly under controlled climatic conditions—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.197/198/04.

Scientific Assistant (with an honours degree in biological sciences and able to write correct English, and preferably with some knowledge of foreign languages), for work including the collation, abstracting and reviewing of biological literature—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge.

Scientific Officer (with first- or second-class honours degree in physics, with experience in the detection and measurement of nuclear radiations and a good practical and theoretical knowledge of electronic counting techniques), to work in conjunction with a group of chemists engaged in research on radioactive materials—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 161/WGH/34.

Scientific Officers (with first- or second-class honours degree in physics or electrical engineering), at Royal Air Force Stations in Buckinghamshire and Norfolk, for operational research duties and theoretical studies in communications and general electronics—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A109/54A.

Senior Lecturer or Lecturer in Pathology—The Registrar, The University, Sheffield.

THE OPPENHEIMER CASE

THE decision of the Atomic Energy Commission by a vote of four to one, as announced on June 29, that Dr. J. R. Oppenheimer should be denied access to restricted data because, on the record before the Commission, he was not entitled to the continued confidence of the Government and of the Commission "because of the proof of fundamental defects in his 'character' " is, of course, a matter of domestic policy within the United States. Even had, however, Great Britain and the United States not been somewhat "mixed up" (Sir Winston Churchill's phrase) in the early development of the atom bomb, the termination in this manner of the Government career of one who had rendered such outstanding services in this field could not but be a matter of profound interest, if not concern, to scientific circles in Britain. His services could scarcely be utilized, for example, by the European Organization for Nuclear Research or the new international agency to promote the use of atomic energy for peaceful purposes without some embarrassment or at least raising some awkward questions for the United States. Moreover, as the B.B.C. Reith Lecturer of 1953, Dr. Oppenheimer's name and achievements in science have been brought before millions with whom they might otherwise have been unfamiliar. The last of the lectures was delivered several weeks before Dr. Oppenheimer was notified, on December 23, that his security clearance had been suspended. Nevertheless, the shock to public opinion generally is sufficiently great for a clear understanding of what has really taken place and what is implied in the decision to be matters of public importance as well as of scientific interest.

On the scientific side there are other important aspects. It has been generally known in Britain that before the Atomic Energy Commission announced its decision, and while the Personnel Security Board, appointed by the Commission, under the chairmanship of Mr. Gordon Gray, was conducting its hearing, numerous leading American scientists had affirmed their faith in Dr. Oppenheimer, and Dr. Du Bridge and Mr. Gordon Dean, a former chairman of the Atomic Energy Commission, had made statements in his support. The Executive Committee of the Federation of American Scientists and a number of physicists at the University of Illinois, many of whom had been closely associated with Dr. Oppenheimer, had testified to his loyalty and expressed concern at his suspension. Moreover, the recommendation of the Personnel Security Board that it would not be clearly consistent with the security interests of the United States to reinstate Dr. Oppenheimer's clearance rested on the opinion of the chairman, Mr. Gordon Gray, and one member of the Board, Mr. T. A. Morgan, and was opposed by Dr. W. V. Evans, the sole scientist on the Board, who recommended that Dr. Oppenheimer's clearance be reinstated. Further, the dissentient from the Atomic Energy Commission's decision was also a scientist, Dr. H. D. Smyth, well known as the author of the Smyth Report of 1945.

In such circumstances some attempt to appraise the situation impartially is essential, if only to avoid misunderstanding or recriminations between partners in what was once a joint enterprise and which may in the future become increasingly one again. This is the more essential in that the circumstances in which the inquiry into Dr. Oppenheimer's loyalty was reopened are such as to confuse the real issues—issues which are of importance to scientists everywhere, and not simply for those concerned with nuclear physics or the development of atomic energy in the United States. Fortunately, they have been well stated, independently of the Oppenheimer case, by American writers themselves such as Prof. W. Gellhorn, Prof. H. S. Commager, and recently by N. D. K. Price in his "Government and Science".

The Personnel Security Board itself was obviously aware of the importance of having some such yardstick by which to reach its decision after hearing about forty witnesses, including Dr. Oppenheimer, and examining some three thousand pages of testimony. In the twenty-three pages of its own findings and recommendations it attempts to set forth frankly some of these major issues and questions which it recognizes as possibly even more important than the outcome of the inquiry itself. Moreover, both the concurring and the dissenting opinions of the Atomic Energy Commissioners indicate a certain confusion of thought and clash of opinion over the ideas of loyalty and activity and the extent to which they can be fostered in a free community and the means by which it is possible to do so.

First, however, it should be said that the texts of the principal documents and letters of the Personnel Security Board, the Atomic Energy Commission and its general manager now published leave no doubt as to the fairness and thoroughness of the inquiry. To this, Mr. L. K. Garrison, Dr. Oppenheimer's attorney, pays generous testimony. Some of the assumptions made by Mr. Gray and his colleagues in reaching their findings may be naive and their soundness is questionable; but there can be no question that they have carried out, with outstanding patience, consideration and integrity, a difficult task which had been handed to them in consequence of a change in the security regulations of the United States and in the climate of opinion.

That fact must be kept in mind if we are to understand the apparent inconsistency between the Board's vindication of Dr. Oppenheimer's loyalty and discretion and the recommendation that he should not be reinstated. Dr. Oppenheimer, as is known to all scientists, took a leading part in developing the atom bomb in the United States, and his work for the Atomic Energy Commission since the War has been highly praised by the chairman of that Commission. Of his services here the Security Board says:

> "The impact of his influence was felt immediately and increased progressively as his services were used. The Nation owes these scientists, we believe, a great debt of gratitude for loyal and magnificent service. This is particularly true with respect to Dr. Oppenheimer".

On the loyalty issue, in recording their conclusion that Dr. Oppenheimer is a loyal citizen, it adds:

> "The Board believes, however, that there is no indication of disloyalty on the part of Dr. Oppenheimer by reason of any present Communist affiliation, despite Dr. Oppenheimer's poor judgment in continuing some of his past associations into the present. Furthermore, the Board had before it eloquent and convincing testimony of Dr. Oppenheimer's deep devotion to his country in recent years and a multitude of evidence with respect to active service in all sorts of government undertakings to which he was repeatedly called as a participant and as a consultant. . . . The Board was impressed by the fact that even those who were critical of Dr. Oppenheimer's judgment and activities or lack of activities, without exception, testified to their belief in his loyalty".

In spite of this clear conclusion that Dr. Oppenheimer is a loyal citizen, the majority of the Board were unable to recommend that "the reinstatement of his clearance would not be a danger to the common defence and security". The case, as has already been indicated, was reopened because of a change in the security regulations and in the climate of national opinion. The accusations against Dr. Oppenheimer considered by the Board fall into two main categories: those which concern his contacts prior to 1943 with Communists or Communist-sponsored groups; and those which relate to his opposition later to the development of the thermonuclear or hydrogen bomb.

Of the first, the majority of the Board found that Dr. Oppenheimer's "continuing conduct and associations have reflected a serious disregard for the requirements of the security system", and they also found "a susceptibility to influence which could have serious implications for the security interests of the country". Of the second they found that his conduct in the hydrogen bomb programme was "sufficiently disturbing as to raise a doubt whether his further participation, if characterized by the same attitudes in a Government programme relating to the national defence, would be clearly consistent with the best interests of security".

In reaching its decision on the first set of facts, which were substantially known to military intelligence when Dr. Oppenheimer was placed in charge of the atom bomb development at Los Alamos and to the Atomic Energy Commission when he became chairman of the General Advisory Committee of that Commission, the Security Board has obviously been influenced by the climate of opinion and the doctrine of guilt by association against which Prof. Commager protested with such clarity and force. Admittedly, Dr. Oppenheimer has shown poor judgment in continuing some of his past associations; but, as the Board itself points out, his sympathetic interests diminished from 1942 to apparent complete rejection in 1946, and they are in part family associations. It asks, indeed, the question whether an individual, who has been a member of the Communist Party or closely associated with it, can later on so comport himself personally, so clearly demonstrate a renunciation of interest and sympathy, so unequivocally display his zeal for his country and its security as to overcome the presumption of security risk. The Board believes this to be possible and that it should be a part of the security policy of the United States; but in making this assumption, it appears also to be making the naïve if not arrogant concept that, in its own words, "the Government can search its own soul and the soul of an individual whose relationship to his Government is in question with full protection of the rights and interests of both".

Such prescience has scarcely been claimed even under a totalitarian regime, and it is difficult also to accept the Board's contention that the proceedings have shown that such investigations can be conducted with complete disregard of public clamour and private pressures. That such investigations can be conducted calmly, fairly and with dignity signifies little in comparison with the harm which they are liable to do to creative and sensitive minds. The charges brought against Dr. Oppenheimer required examination when they were first made; but the Editorial Board of the *Bulletin of the Atomic Scientists* will not be the only body to whom it will seem contrary to both decency and common-sense to revive them now from the irrelevance to which a brilliant record of national service had relegated them. To do so seems to make a particular security system the master rather than the servant of national interest.

The Security Board does indeed seem to be uneasy on this score. It points out that the protection and support of the entire security system itself has had insufficient public attention, and at least by implication it admits the right of criticism of, or dissent from, that system. Having gone so far it fails, however, to recognize that any particular security system may in its structure or administration have defects which impair the dynamic and creative elements which are the real source of national strength. "It seems to us", writes the Editorial Board of the *Bulletin of the Atomic Scientists*, "a breach of faith on the part of the Government to call upon a man to assume such heavy responsibilities in full knowledge of his life history and then, after he has demonstrably done his best and given the most valuable service to the nation, to use the facts which were substantially known all the time to cast aspersions on his integrity". Others may well feel that in accepting a task which should not have been given to it, the Security Board was led into making claims of competence in areas where it had no title.

The real issue here was, in face of the new security regulations, whether, as a matter of national policy, Dr. Oppenheimer should be employed regardless of the narrow standards laid down for screening a typist or a clerk. Perhaps only the United States could have spared the time and energy of distinguished men to discover whether Dr. Oppenheimer was a security risk according to its standards. Unquestionably he was, but having regard to the framework of American philosophy it was not right to expect the Security Board to make any such distinction even on the ground of critical national need. Only the President can fairly accept responsibility for any such decision, nor can he evade the final responsibility if the climate of opinion forces on the Executive changes in the security system which endanger the real strength of the nation.

One further passage in the Security Board's findings touches on a particular aspect of this question. It was repeatedly confronted with the question whether, in determining the security status of a scientist, the Government must take into account the reactions of, and the possible impact upon, all other scientists. Even here, however, the Board scarcely seems to appreciate the effect of security inquiries and procedure upon scientific and other creative work. The Board recognizes that it is encouraging evidence of the vitality of society when so many scientists spring to the defence of one who is regarded as unfairly attacked; but the deeper issue that an ill-judged security system may endanger the roots of security is not recognized. It is not that scientists, for example, claim any special privilege to be exempt from security regulations or inquiries. The Board itself testifies to their loyalty and responsibility. The Oppenheimer case does, however, seem to raise the fundamental issue of the appropriateness of the whole security system and whether its structure or administration are not, in fact, eroding the basis of a free society.

The second group of accusations regarding Dr. Oppenheimer's opposition to the development of the hydrogen bomb raises an equally fundamental issue. The Security Board found that Dr. Oppenheimer's conduct was sufficiently disturbing as to raise a doubt as to whether his future participation, if characterized by the same attitudes in a Government programme relating to the national defence, would be clearly consistent with the best interests of security. This finding is in contrast, as Mr. Garrison pointed out in the letter already quoted, with the fact that the basic allegations in this matter were regarded as disproved. The Board agreed that Dr. Oppenheimer's opposition to the hydrogen bomb programme "involved no lack of loyalty to the United States, or attachment to the Soviet Union", that his opinions regarding the development of the hydrogen bomb were shared by other competent and devoted individuals, both in and out of Government, and that it could be assumed that these opinions were motivated by deep moral conviction". After the decisions in January 1950 to proceed with the development of the hydrogen bomb, Dr. Oppenheimer did not oppose the project in a positive or open manner, nor did he decline to co-operate in the project, and the allegations that he urged other scientists not to work on the hydrogen bomb programme were unfounded.

Nevertheless, the Security Board concluded that the "security interests of the United States were affected by Dr. Oppenheimer's attitude because they believed that, had Dr. Oppenheimer given his enthusiastic support to the programme, a concerted effort would have been initiated at an earlier date and because, following the President's decision, he did not show the enthusiastic support for the programme which might have been expected of the chief atomic adviser to the Government under the circumstances". Dr. Garrison argues that the injection into a security case of a scientist's alleged lack of enthusiasm for a particular programme is fraught with grave consequences to the United States, and his contention is supported by comments of other scientists which indicate that this is the aspect that the majority of scientists in the States find most disturbing.

"How can a scientist", asks Mr. Garrison, "risk advising the Government if he is told at some later day a security board may weigh in the balance the degree of his enthusiasm for some official programme, or that he may be held accountable for a failure to communicate to the scientific community his full acceptance of such a programme ?". The Security Board did not find that Dr. Oppenheimer urged other scientists not to work on the hydrogen bomb programme, although it believes that enthusiastic support on his part would have encouraged other leading scientists to work on it. Nevertheless, it found that "if Dr. Oppenheimer had enthusiastically supported the thermonuclear programme before or after the determination of national policy, the hydrogen bomb project would have been pursued with considerably more vigour, thus increasing the possibility of certain success in this field".

To argue thus introduces an entirely new standard of acceptability for employment as a technical adviser. It has not previously been suggested that a government employee or consultant must give his enthusiastic support to official policy. Dr. Oppenheimer was not alone in opposing the development of the hydrogen bomb, at least in so far as his opposition was based on the nuclear technology then existing. Nor does even the Security Board challenge Dr. Oppenheimer's right to hold moral or political opinions opposed to that development. It is admitted that when his opinion was rejected he co-operated loyally in the furtherance of the official programme. To dispense with his services on the ground of lack of enthusiasm, instead of doing so by exercising the right possessed by any government to change its advisers without challenging either their competence or their patriotism, involves grave risk that men of creative, original and independent minds will no longer care to enter the government service, or indeed be accepted for it, and, as Prof. A. Macbeath remarked at Belfast, the only safeguard against major mistakes has then gone.

Mr. N. D. K. Price, writing on this issue of the hydrogen bomb before the Oppenheimer case developed, remarked: "If there were any problem on which the highest public officials should accept their proper responsibility and in which scientific advisers should not be held accountable except for the accuracy of their scientific advice this was the problem. . . . Published articles that attack the motives of scientific advisers will obviously weaken the government's ability to get scientific advice".

The danger of alienating scientific advisers has been emphasized by Dr. Vannevar Bush in an article which advocated an overhaul of the entire system of security clearance within the executive branch of the Government. The comments of other scientists in the scientific press of the United States indicate that it is the security system itself, rather than Dr. Oppenheimer, that is on trial. The issue is one between the positive and the negative concepts of security. The lone scientists on the Security Board and on the Atomic Energy Commission, attaching first importance to the former, were of opinion that Dr. Oppenheimer's services should be retained; their colleagues, guided by the negative concept, voted to dispense with them. In this connexion it should be noted that the Security Board said: "It seemed to us that an alternative recommendation would be possible if we were allowed to exercise mature practical judgment, without the rigid circumscription of regulations and criteria established for us".

There is one further comment to be made here on the introduction of this new concept of enthusiasm as fitness for service. That involves a threat to the freedom of the scientific conscience which seems, indeed, to have troubled the Commissioners. More important, however, even than the possible discouragement to first-class men from entering the service of their country, the introduction of this criteria of enthusiasm destroys the real basis of advice. What a nation requires primarily of its advisers is not enthusiasm but responsibility. That is the condition on which advice is given, and it implies loyalty as well as the judgment and the wisdom to select and apply the relevant knowledge. Responsibility does not and cannot condone the subordination of judgment to any political doctrine or policy.

Once again, therefore, we are brought face to face with the voice of power and responsibility. Unless our advisers are trusted and are allowed discretion, they cannot give us that independent judgment, that unimpeded inquiry and scrutiny which are the source of major and vital advances and the safeguard against major mistakes. Perhaps the most hopeful feature of the whole business is the extent to which these issues have been recognized by American scientists themselves. It is not so much the way in which they rallied in support of Dr. Oppenheimer, with whose opinions and judgments many of them have often disagreed. It is rather that they have recognized with remarkable unanimity that security regulations that enforce a decision which puts a blot not clearly justifiable on the reputation of an outstanding American scientist, generate distrust between American scientists and their government and endanger the readiness of government advisers to give the government the benefit of their best thought, are themselves a danger to the security of the country.

Meanwhile, in the United States other atomic scientists have had their zeal for their work damped by what they regard as the unrealistic standards applied in Dr. Oppenheimer's case and may hesitate to renew their contracts with the Atomic Energy Commission, just as promising young scientists may now prefer to seek employment elsewhere. Already secrecy regulations and the impediment they offer to the free exchange of knowledge tend to discourage a certain type of the ablest young minds from entering this field. Once the opinion gains ground that scientists in government service have to work under such restrictive conditions or in such an atmosphere of suspicion that creative and original work and the spirit of free inquiry are inhibited, the quality of the State service will be irreparably impaired.

In Britain, as in the United States, national security depends primarily on the country's ability to enlist in its service a sufficient proportion of the ablest minds among its scientists and technologists and allowing them to work under conditions which give full scope to their originality and vitality. Security regulations which do not subserve this condition themselves endanger national security. The protests that have been forthcoming over the Oppenheimer decision may indeed offer some safeguard that it will not form a precedent for "insidious encroachments by men of zeal, well-meaning but without understanding", which are the major threat to national security as well as freedom. More positively, it may perhaps be hoped that the co-operation which will be demanded if the United States is to participate effectively in the new world agency to promote the growth and spread of atomic energy for peaceful purposes, announced by President Eisenhower on September 6, will itself encourage the realistic appraisal of the security system which American scientists have urged and the formation of a climate of opinion in which the balance of freedom and security and the issues of responsibility and power are more clearly understood, and guarded with imagination and understanding as well as zeal.

As has been said, the manner in which Dr. Oppenheimer has been dismissed makes it difficult for the free world to avail itself of the services of the man whom Dr. Smyth describes as "one of the most knowledgeable and lucid physicists we have" without raising awkward issues.

But the really important questions which the Security Board and the Atomic Energy Commission have left unanswered are not concerned with Dr. Oppenheimer at all, or at least only indirectly. Was it really necessary for three such distinguished men to spend their time and energy on determining the answer to a question which was obvious to common sense? Apart from the question whether even the most richly endowed nation can afford to divert an unlimited amount of its man-power to security investigations, the contrast between the ambiguous answers produced after so much voluminous inquiry and the swiftness and perspicacity with which Sir John Woods's committee investigating the Crichel Down episode in Britain reported on issues touching the public interest no less vitally is startling. Almost inevitably it suggests that there may be substance in what some American scientists are saying, and that Dr. Oppenheimer has been dismissed because his opinions were unpalatable to the authorities, and particularly the military authorities, who have chosen this retrograde method of removing an adviser so as to minimize the possibility that others may avail themselves of his advice or services. Meanwhile, grave damage has been done to the co-operation and understanding between scientists and government, without which no effective system of defence can to-day be developed. To establish conditions in which the scientific adviser can make his full and most effective contribution to the tasks of defence and of peace is an imperative over-riding necessity for the free world, and until clear answers are given to the questions which are raised by the case of Dr. Oppenheimer the belief may well grow that its significance is to be seen, not in comparison with the recent Crichel Down episode, but in the analogy with the case of Dr. Dreyfus two generations ago.

SIR WILLIAM PETTY: A GENIUS OF THE SEVENTEENTH CENTURY

Sir William Petty

Portrait of a Genius. By E. Strauss. Pp. 260. (London: The Bodley Head, 1954.) 25s. net.

THE mid-seventeenth century was for England an exciting and expansive era. Increasing population and wealth, with accompanying changes in the structure of society, created new problems of political organization; the development of industrial technique and sea-borne trade gave a new importance to commercial policy; and the scientific movement offered not only the greatest intellectual stimulus of the time, but provided also a hope that through its mastery of Nature the material progress of mankind would steadily advance. Many reactions to the opportunity of the age were possible. Some men prospered in wealth while understanding little of the changes that had made their success possible. Others who achieved distinction in science or philosophy were passive to the social currents by which they were borne. A peculiar interest in the career of Sir William Petty (1623–87) is that he was of both camps—a *parvenu* opportunist who had won wealth and title by exploiting the devastation of Ireland, and at the same time a philosopher, the father of political economy and an Original Fellow of the Royal Society.

In a tough society Petty was no weakling, as Mr. E. Strauss shows. He was ambitious to rise in the world, and not too scrupulous. An accident took him from the sea to a Jesuit College; a little learning brought him to Oxford, the medical profession and to many useful friends. But Petty was destined to be neither a Sydenham nor a Radcliffe. Ireland called him, as it had called all adventurers since Elizabeth's reign. Although he began with little capital, the Down Survey and the distribution of land to Cromwell's veterans yielded him a wonderful opening, so that by outwitting the administration and shrewd bargaining with the soldiers he emerged possessed of at least thirty thousand acres and a heritage of litigation.

With wealth assured, Petty's ambition turned to politics. Mr. Strauss analyses the means by which this servant of the Cromwellian régime secured something more than tolerance from the restored Stuarts. He won rather less by his change of heart than some of his colleagues in the Royal Society. His massive proposals for increasing population, production and revenue were ignored. Even the scientists were surprisingly indifferent to his venture with the double-bottomed boat. This was partly because (as Mr. Strauss says) Petty preserved ideals and policies which were no longer in favour, such as opposition to the aggrandisement of France; but it was also no doubt due to a more fundamental disability. Attractive as he was to his friends, and greatly as he impressed them by his intellectual capacity, Petty was a more difficult character than Mr. Strauss seems willing to admit. His one great exercise in authority and administration—the Down Survey—proves that he had a superlative ability for arousing hostility and envy; and there is no sign that their main cause, Petty's love of money, diminished with age. Rather, his every scheme for enriching England was designed to enrich Petty, too. Perhaps, as with other philosopher-kings, it was best for the philosopher in Petty that his kingship should remain frustrated.

It is when he comes to examine Petty's writings on political economy that Mr. Strauss's claim of genius is best sustained. The Down Survey (1655–56) was indeed an astonishing feat of organization, but it should be remembered that it was effected with the aid of a disciplined military force; and important as the Survey was for the cartography of Ireland, Petty contributed nothing to the development of surveying methods. It was in his riper years as a cabinet statesman, in the many papers that remained unpublished until after his death, that the originality and power of Petty's mind were revealed. For if his schemes for the demographic and economic reform of England were often fanciful in detail, they were based on theoretical conceptions which (in Mr. Strauss's words) "provided the starting-point for the growth of classical economic science up to the time of Adam Smith, David Ricardo and Karl Marx". The foundation of these conceptions was Petty's notion of wealth, far removed from the crude bullionist equation of wealth with plenty of money, as residing in a dense and productive population. Only less original was his grasp of the importance of statistical information, though Mr. Strauss concludes that John Graunt's share in the authorship of the famous "Observations upon the London Bills of Mortality . . ." was far from trivial. Petty's conclusions were necessarily often based on numerical conjectures, and he added nothing to the mathematical aspects of this subject; what he did do was to indicate the kind of information that could usefully be collected, and the type of answer that statesmen and administrators could extract from it.

As a natural scientist, on the other hand, Petty had no great merit. His Baconian ideas were rendered outmoded by the growth of disinterested research in the several sciences. Something of his intellectual virtues and defects are portrayed in his remark in 1687 that "As for Mr. Newton's book, I would give £500 to have been the author of it". His one great adventure in applied science, the double-bottomed boat, proved a dismal failure. In navigation, as in politics, the brilliant amateur was outdistanced by plodding professionals.

Mr. Strauss has given a full and interesting account of this extraordinary career, which is a fitting supplement to Lord Lansdowne's volumes of twenty-five years ago. He has placed Petty firmly in his historical context, and evaluated skilfully the merit of his varied writings. If in seeking to justify the unbounded admiration felt by many better-known contemporaries (including John Evelyn and Samuel Pepys) for this rather neglected figure in the "century of genius", Mr. Strauss has made some claims for Petty of which the strength is not immediately obvious, he has nevertheless given a fair picture of the weaknesses in Petty's intellect and character. He has written an excellent book. A. R. HALL

MINERALS USED IN INDUSTRY

Minerals for the Chemical and Allied Industries

By Sydney J. Johnstone. Pp. 692. (London: Chapman and Hall, Ltd., 1954.) 75*s*. net.

THIS is a concise, encyclopædic account of the sources, properties, uses and standard specifications of a great variety of mineral substances that now find application in modern chemical and related industries and, incidentally, in the metallurgical industry. The term 'mineral', as used here, is to be interpreted in its very broadest sense, implying substances obtained out of the earth, either directly, or indirectly from complex ores, and also certain synthetic derivatives of such minerals. Thus, the main section headings include such diverse materials as slate waste, rhenium, wollastonite, perlite, mercury, nitrates and ochre. In fact, many of the minerals dealt with are described under sections bearing the name of the principal element or substance, metallic or otherwise, entering into their composition, so that other headings are aluminium, titanium, iodine, sulphur, silica, and so on. The main sections are in alphabetical order, an arrangement doubtless convenient to the commercial users for whom the book is primarily intended. An adequate index assists in rapid reference to more specific minerals. There is no main heading for iron (a rather surprising omission), which seems to be accounted for by the fact that the materials described are essentially those in use or potentially useful for chemical rather than metallurgical industry, although in the case of many other metals their metallurgical applications receive mention. However, certain naturally occurring ferruginous minerals are included under other headings, and the applications of other metals—for example, manganese and zirconium—in iron metallurgy are mentioned in the appropriate sections.

The fact that this book has been prepared by the former principal of the Mineral Resources Department of the Imperial Institute, London, who also served as head of the Commodities Section of the Ministry of Economic Warfare during the Second World War, is sufficient guarantee of its authoritative character. It is based on a series of articles that he published in *The Industrial Chemist and Chemical Manufacturer* between 1946 and 1949. Much new material has been incorporated, however, bringing the text thoroughly up to date; and accounts of a number of minerals not included in these articles have been added. Each section concludes with a selected bibliography of sources from which more detailed information is obtainable. Statistical details of sources and production in recent years are given, so far as they are available, and also references to countries that were able to produce increased quantities of certain materials during the War. All this material has been collected from many widely scattered sources, and presented concisely in an easily accessible form.

The book makes instructive reading for all interested in economic minerals and their uses, and is particularly informative, for example, on the uses to which some of the rarer metals are now being put. It will prove invaluable to the industrial chemist, for whom it is especially intended; but should also be useful, as a reference book, in those technical and other educational establishments where the curriculum includes the economic applications of chemistry and mineralogy. V. A. EYLES

THE FIRST COLONIZATION OF BRITAIN BY FARMERS

The Neolithic Cultures of the British Isles

A Study of the Stone-using Agricultural Communities of Britain in the Second Millennium B.C. By Prof. Stuart Piggott. Pp. xix+420+12 plates. (Cambridge: At the University Press, 1954.) 70s. net.

WITH the aid of soberly scientific imagination and historical insight, the fragmentary results of fossilized behaviour that constitute the archæological record have been here interpreted by Prof. Stuart Piggott as documenting the first colonization of the British Isles by farmers, the adaptations of their exotic cultures to the insular environment and the reactions of surviving Mesolithic 'natives' to the impact. The result is no tedious catalogue of invasions (though to explain the facts the author has to postulate at least six distinct bands of "Neolithic" immigrants apart from several groups of "Beaker folk"), but genuine history—at least economic history—as concrete as the limitations of archæological data allow; for example, the lively account of the autumn round-up of stock in "causewayed camps" is no product of fancy, but a legitimate inference from observed phenomena that have been factually described. For the archæological data are here assembled, classified and presented so fully that a sceptical reader can discern possible inconsistencies even in statements that the author accepts (for example, a "cremation" of which no burnt bone survives; the account of the Baltinglass cairn is vitiated only by a defect in the published plan that Prof. Piggott justifiably followed) and illustrated by figures and maps that are artistic as well as instructive. As a result, Prof. Piggott's work is a standard and indispensable source-book from which all further work on the problems of the period must start. For problems still are left.

Most of the material so exhaustively surveyed has been accumulated during the past twenty-five years, much in the past decade, while some of the most reliable data are due to the author's own excavations at well-selected sites. At the same time, Prof. Piggott has extracted every scrap of serviceable information from older accounts of digs into flint mines and long barrows. The interpretative concepts are likewise novel and original. As to chronology, the book's sub-title will advise the reader that the Neolithic period surveyed does not begin, as it would have a quarter of a century ago, with the end of the Pleistocene. Its end will still surprise many readers; "Neolithic" for Piggott does not end, as has been assumed for the past fifty years, with the advent of "the Beaker folk". Though typologically early bronze weapons are doubtless found, albeit very rarely, in their graves, and exports on the Continent of Europe imply even the contemporary existence of a school of local metallurgy at least in Ireland, societies here described undoubtedly continued to maintain purely Neolithic traditions after the Beaker invasion and down to the rise of the Wessex culture. After all, on Montelius's system for Scandinavia, Neolithic IV coincides with Bronze Age I, and a similar usage would be legitimate here.

The Beaker invaders are not here treated among "the stone-using agricultural communities of Britain"; they are excluded not as consumers of metal ware, but as exponents of "the novel rite of individual burial", while "some form of collective burial appears to be characteristic of all the neolithic cultures here described". Therewith, "collective burial" too is given a novel sense, being applied to cremations interred in individual graves, if these are grouped in closed cemeteries, as much as to the burial of several persons' remains in a common tomb, to which latter rite the term had hitherto been restricted. Admitted cases of individual burial in "Neolithic" cultures are explained as due to the influence of the Beaker invaders, even though at Linch Hill such a burial was stratigraphically prior to an interment with a Beaker.

Original, too, and fruitful is Prof. Piggott's concept of "Secondary Neolithic cultures", in which such elements as "can be regarded as intrusive" are "inextricably mixed with other features which have a long local ancestry in Mesolithic cultures", whereas the Primary cultures, associated with the first farmer-colonists, should represent "a virtual transfer of French early Neolithic traditions to this country". But in the sequel it is suggested that the distinctive secular monuments of the colonists—the "causewayed camps" (which are really cattle corrals)—together with the techniques of skin-dressing illustrated in them, may be due to "intermixture with indigenous hunter-fishers", while their long barrows might have been as appositely compared to Megalithic tombs in north-east Germany as to the *tertres allongés* of Morbihan. On the other hand, Secondary Neolithic pottery of the Peterborough class is so like the pitted ware of Sweden that the author inclines to regard its "appearance as an indication of settlement in south-east England of people arriving by sea from Scandinavia". Now, since the book went to the press (in 1951), Becker has shown that the makers of pitted ware played just the same part in the distribution of flint axes in Scandinavia as Secondary Neolithic folk played in Britain in the remarkable trade in axes from the Langdale, Penmaen Mawr and Antrim factories which systematic petrological examination has revealed recently, but in time for description by Prof. Piggott. This three-year interval between composition and publication must also be remembered in connexion with other comparisons with North European material. The author has just failed to translate the older Danish–Swedish chronological terminology into that adopted during the past five years, and consequently seems to have inverted the chronological relations between the Beacharra C and Peterborough phases here, in so far as these are deduced from North European parallels. In the precocious science of prehistoric archæology progress is so rapid and publication has become so slow that any book must be to some extent out of date when it is issued. Prof. Piggott has written an exhaustive and authoritative account of Neolithic Britain as it appeared in 1951. V. G. CHILDE

A Bibliography of the Research in Tissue Culture, 1884 to 1950

(An Index to the Literature of the Living Cell Cultivated in Vitro.) Prepared by Margaret R. Murray and Gertrude Kopech. Vol. 1: A–K. Pp. xxviii+840. Vol. 2: L–Z. Pp. 841–1742. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1953.) 24 dollars the set.

THIS monumental bibliography of the literature on tissue culture, which occupies two large volumes, is indeed a remarkable achievement. The plan to produce this work was conceived in 1946 at the Hershey Conference and has been sponsored throughout by the Tissue Culture Commission, which was founded at this meeting, and by its successor, the Tissue Culture Association. When the scheme was first launched, the vast size of the literature was not fully realized, and the authors and sponsors had to surmount many unforeseen difficulties, both financial and editorial, before the project was at length completed.

In the preface, tissue culture is defined as "the maintenance of isolated portions of multicellular organisms in artificial containers outside the individual for considerable periods of time". To prepare the book, "29,000 articles were read in their entirety"—a truly horrifying thought—and, from these, 15,000 were selected as being covered by the definition; this number was expanded by excellent cross-indexing to 86,000 entries.

It is astonishing to discover how much work has been done by means of the tissue culture technique in a wide variety of fields. To have this exhaustive collection of references assembled in one book, however large, is a blessing not only to all those who use the method, but also to many others who are concerned with the information provided by experiments on tissue cultures. The authors are to be warmly congratulated on the scholarly way in which they have accomplished their formidable task, and they can rest assured that grateful colleagues throughout the world will "arise up and call [them] blessed".

Journal of the Institute of Metals

Vol. 80, 1951–52. Editor: N. B. Vaughan. Pp. xvi+728+113 plates. (London: Institute of Metals, 1952.)

THE present volume is the first to appear in the enlarged size (11 in. × 9 in.). This new format has enabled diagrams and photographs to be reproduced more satisfactorily; but the volume of 728 pages weighs more than 5¼ lb. and is too heavy for convenient handling, while its cloth binding is insufficiently strong to stand up to normal laboratory or library use. The volume contains seventy-seven papers, and a further disadvantage of this large size is that a single reader in a library immobilizes seventy-six papers besides the one he is consulting. It is to be hoped, therefore, that future volumes will be smaller and published at more frequent intervals.

Except for its inconvenient weight, the volume is excellent. It is well and clearly printed, and the standard of reproduction of tables, diagrams and photographs is admirable. The papers cover a wide range of subjects, and the majority can be read from the point of view of general scientific interest, quite apart from industrial applications. Work on the structure of metals and alloys is prominent, and the volume includes the presidential address by Dr. C.-J. Smithells, the twenty-second Autumn Lecture on "Electrochemistry and the Science of Metals" by Prof. R. Piontelli, and the forty-second May Lecture by Dr. J. J. P. Staudinger on "The Place of Plastics in the Order of Matter". There are also a summary of a discussion on metal economics and a symposium on equipment for the thermal treatment of non-ferrous metals and alloys. W. HUME-ROTHERY

Synthetic Organic Chemistry

By Romeo B. Wagner and Prof. Harry D. Zook. Pp. xii+887. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 92s. net.

THIS comprehensive work aims at giving a concise summary of the chief synthetic methods used in organic chemistry for preparing compounds of single and dual function. For this purpose the authors have undertaken an exhaustive examination of twenty of the leading journals and books dealing with organic chemistry from 1919 to 1950.

The thirty-nine chapters bear such headings as acetylenic compounds, halides, ethers, lactones, *iso*cyanates, amines, imines, hydrazines, diazo and diazonium compounds, and sulphonic acids. As an illustrative example, Chapter 24, dealing with amines, adduces forty methods for preparing this type, including the reduction, or the hydrolysis, of various other types; degradation of amides, acyl azides and hydroxamic acids; ring dehydrogenation; and various ways of applying Grignard reagents. A short discussion, with copious references for each method, is followed by twelve tables which summarize the preparative methods, yields and physical properties of some seven hundred individual compounds listed under the heads of amines, diamines, olefinic and acetylenic amines, halo- and hydroxy-amines, amino-ethers, -aldehydes, -ketones, -acids, -esters and -cyanides. The chapter closes with a list of 561 references to original sources finding mention in it.

The enormous amount of information in this time-saving compendium is set out clearly and systematically, the book is well printed, and it can be commended to organic chemists and biochemists as a reliable and up-to-date guide through the maze of modern synthetical methods. JOHN READ

The Heron

By Frank A. Lowe. (New Naturalist Special Volume.) Pp. xiii+177+9 plates. (London: William Collins, Sons and Co., Ltd., 1954.) 18s. net.

BOOKS about birds continue to come from the publishers in steady numbers and are evidence of the ever-growing appreciation of ornithology. In "The Heron" Mr. F. A. Lowe has written an interesting monograph and an excellent addition to the "New Naturalist" series of volumes. Based on long observation of the heron breeding colony in Dam Wood, Lancashire, his book ranges over world distribution and populations, breeding biology, the mechanics of flight and dispersal, the heron in history and folk-lore, etc. It is a painstaking and thorough survey, written in an unpretentious style, that will be read with pleasure alike by the experienced ornithologist and the recent recruit to the ranks of bird-lovers.

The illustrations range from maps and diagrams to photographs taken in the wild, and include as frontispiece a photograph in colour of a heron at its nest. Where all are so excellent, it seems invidious to carp; but it would certainly have been pleasing had it been possible to include one or two heron portraits by outstanding artists, including an example of the heron in Japanese art. FRANCES PITT

PHYSIOLOGICAL ASPECTS OF THE HEATING AND VENTILATION OF HOUSES IN BRITAIN

AT the recent meeting in Oxford of the British Association, the first session of Section I (Physiology), held on September 2, dealt with various physiological aspects of heating and ventilation, the emphasis of the papers being on the requirements of houses in Great Britain.

In his introduction the chairman, Dr. Thomas Bedford, gave a brief survey of the results of recent studies of thermal comfort and the assessment of environmental warmth. It can be concluded from recent research in the United States that for satisfactory ventilation the supply of fresh air should be at the rate of not less than 600 cu. ft./hr. for each person, and this standard had been accepted by the Egerton Committee as one of the requirements for post-war housing. People doing light work during the winter months in Great Britain liked a temperature of about 65° F. and were reasonably comfortable at temperatures of between 60 and 68° F. With a suitable temperature there should be adequate but not excessive air movement. At room temperatures of about 65° F. the air speed should be between 20 and 40 ft./min. At lower speeds complaints of stuffiness are likely, and at higher speeds sensitive persons will complain of draughts.

Investigations have confirmed that with a given level of warmth most people find conditions pleasanter when the boundary surfaces of a room are warmer than the air than when they are cooler. It is undesirable that the warmth around the head should be appreciably greater than that near the floor. The gradient of air temperature over the height of a man should not be more than 5° F. When a room is heated by panels embedded in the ceiling, the elevation of the mean radiant temperature at head-level due to the warm ceiling should not exceed 4° F. Many buildings are now warmed by heating the floors. Research nearly completed shows that for sedentary people the temperature of the floor surface should not be higher than 75° F.; but people who are moving about can tolerate a rather higher temperature. These figures relate to rooms with an air temperature of about 65° F.

Various scales of warmth have been used for making allowance for different combinations of the individual factors which make up the thermal environment. The best known of these is the American scale of effective temperature. This makes no specific allowance for radiant heat, and during the Second World War it became necessary to attempt some adjustment of the scale to allow for radiation effects. Such an adjustment has been made by using the temperature of a black-globe thermometer instead of the air temperature in calculating the effective temperature. Recent physiological research carried out at the R. N. Tropical Research Unit, Singapore, has shown that this method of adjustment gives good results.

War-time studies have led to certain criticisms of effective temperature as an index of the stress imposed by work in hot environments, but a recent study of the bases of these criticisms has led to the conclusion that effective temperature, properly used, remains a valuable index of warmth. Finally, it was suggested by Dr. Bedford that attention should be given to local methods of warming a person rather than the whole room or the whole house, especially with reference to the requirements of the aged. Dr. E. F. DuBois had asked: "Why overheat 100 tons of house and furniture, when all that is necessary is to warm 100 lb. of grandmother?"

Prof. G. P. Crowden spoke on the heating and ventilation requirements of dwellings. He outlined the climatic factors which affect the control of body temperature and the comfort of the individual, and then detailed the standards set out in the codes of practice drawn up by the British Standards Institution. In living-rooms the temperature should lie between 60 and 68° F. and in bedrooms between 55 and 57° F. In both, the relative humidity should be between 30 and 65 per cent, with a fresh air supply of 600 cu. ft./hr. per person. For kitchens a temperature of 60° F. is specified, with a relative humidity of less than 70 per cent, and the supply of fresh air should be at least 2,000 cu. ft./hr.

Prof. Crowden then went on to describe tests that had been carried out in experimental rooms of the type described as 'kitchen/living-room', with housewives and men of varying ages as the experimental subjects. These tests showed that the provisions for heating and ventilation make it possible to maintain the specified conditions.

When housing schemes were again undertaken after the Second World War, it was evident that building resources would be stretched to the utmost, and methods of economy in building were examined. One obvious way of saving in both cost and materials was to reduce the heights of rooms. Generally it was not permissible to build houses with rooms less than 8 ft. in height; but it was thought by many that rooms 7 ft. 6 in. in height would be quite satisfactory. Others feared that houses with the lower ceilings would be unsatisfactory on grounds of health or of comfort. Prof. Crowden described a survey of some trial houses that were built with rooms only 7 ft. 6 in. high. The families who lived in them did so in comfort. Very few expressed the opinion that they would prefer higher rooms, and the majority had not noticed that the ceilings were lower than usual. The conditions specified in the codes of practice were readily maintained in these houses.

When ordinary gas wash-boilers and cookers were used in small kitchens these became undesirably hot and steamy, and the air was contaminated with products of combustion, unless the ventilation greatly exceeded the 2,000 cu. ft. of fresh air per hour laid down, or unless flues were provided to remove the products of combustion.

Two examples were given of the failure of occupants to make proper use of provisions for ventilating their houses. In one house the excessive use of draught-excluding devices made it impossible to use a solid-fuel fire, while a gas fire made the air unpleasant, even though the heating was inadequate. In the second example, the deliberate restriction of ventilation resulted in four deaths from carbon monoxide poisoning due to the incomplete combustion of coal gas.

In a paper on problems of working conditions in the home, Dr. J. R. Brown described experiments in which women engaged in washing clothes were studied, the work being done without the aid of washing machines. Careful measurements were made of the thermal environment as the work proceeded, the subjective impressions of heat and of moisture of the experimental subjects were noted, their blood pressures and pulse-rates were measured and used for computing the Crampton index of vasomotor tone, and the electrical conductivity of the skin was measured. From experiments carried out under control conditions it was concluded that changes in the Crampton index were related to changes in thermal stress. The numerical value of the index declined as the women subjects felt hotter and more fatigued. It has been found that, until the skin becomes visibly wet with sweat, there is a linear relation between its electrical conductivity and the number of active sweat glands.

Dr. A. Parker spoke on house heating and atmospheric pollution. Domestic chimneys are responsible for a million tons of smoke a year and for a million tons of sulphur dioxide, and the solution to the problem lies in the use of smokeless fuels—gas, electricity and coke—in proper balance. Problems of economics as well as fuel technology arise here. Only one day's supply of gas can be stored, and it is impracticable to store electricity on a large scale, so that the main stand-by must necessarily be solid fuel. Coke should not be regarded as a surplus product arising from the manufacture of gas, but rather the needs for coke and for gas should be taken into account together. People should regard coke as a valuable smokeless fuel in its own right, and not merely as partly-used coal. Dr. Parker thinks the problem is not insoluble. In Britain, he said, people insist on having open fires, and such fires are perhaps desirable in this climate, but there is no prospect of burning bituminous coal in such fires without creating smoke. When convective methods of heating are used, people tend to demand an air temperature about 8° F. higher than with radiant heating, with consequently greater fuel consumption. It might be suggested that district heating should be extended; but with this form of heating it is usual to make a weekly charge for heat without reference to the quantity used, so that the consumer has no incentive to practise economy, with the result that the amount of fuel used per house with district heating is greater than with open fires.

Mr. J. B. Dick spoke about factors of design and construction affecting heating and ventilation in dwellings. It is the experience of the Building Research Station that, with an internal flue, about 40 per cent of the heat from an open fire is delivered into the house, and with such a fire an acceptable standard of comfort can be obtained at lower cost than with a hot-water radiator. It is important not to provide a heating system that will be too costly for the householder to maintain.

Recent improvements in construction were described. An 11-in. cavity wall with a foamed-slag inner leaf has an overall thermal transmittance of only two-thirds that of an 11-in. cavity wall entirely of brick, and a transmittance of less than half that of a solid 9-in. brick wall. The use of glass wool for roof insulation was described. Besides reducing fuel consumption to maintain a given air temperature, good thermal insulation also raises the temperature of the inner surface of external walls and thus enhances comfort. Temperature gradients can be caused by the convection from cold walls or windows. Better insulation of the walls and tubular heaters beneath windows can cure this. Floor heating also helps to prevent these gradients, and when heating is by the admission of warmed air this should enter at low level and air exits should be placed at high level.

The temperatures maintained in houses depend not only on the preferences of the occupants, but also on the cost. Thus, in some experimental houses the temperatures in the living-rooms at 9 p.m. commonly averaged 65° F., but during cold weather the figure fell to 60° F. It was evident that the householders would not pay for the heat then required to maintain a temperature of 65° F. With improved insulation some of the potential saving of fuel may not be realized because higher temperatures are likely to be maintained by the occupants. Hence emphasis must be placed on better insulation without increased capital cost. One way in which this can be achieved is by use of the foamed-slag inner leaf in cavity walls.

Dr. C. G. Douglas, who opened the discussion, believes that the problems of heating and ventilating factories and offices are easier than those relating to houses. Instrumental methods have been devised for the study of the indoor environment, and the difficulties that now arise are mainly economic. It is important to consider what could be done to provide comfortable warmth for aged people with limited resources. The high cost of coal has driven many people to use kerosene for supplementary heating.

AHMEDABAD TEXTILE INDUSTRY'S RESEARCH ASSOCIATION

By DR. VIKRAM A. SARABHAI

Director

ON April 10, Mr. Jawaharlal Nehru, Prime Minister of India, opened the new laboratory building at Navrangpura, Ahmedabad 9, of the Ahmedabad Textile Industry's Research Association, the foundation stone of which was laid in November 1950 by the late Sardar Vallabhbhai Patel, Deputy Prime Minister of India. The Association is modelled on the same lines as the research associations in Great Britain, and this constitutes the first enterprise of its kind in which industry and the Government of India have co-operated in the field of research. The past five years have witnessed the growth in India of a chain of national laboratories inspired by Sir Shanti Bhatnagar, director of the Council of Scientific and Industrial Research, and Sir Shanti has also been actively associated with the growth and development of the new Association at Ahmedabad, which is the second largest centre of the textile industry in India.

The idea of establishing a textile research laboratory maintained by the joint effort of industry and the Government of India was first conceived by the Ahmedabad Millowners' Association in 1944, and the Ahmedabad Textile Industry's Research Association was registered in December 1947. Its seventy-one founder-members made an initial contribution of approximately £370,000 towards the initial expenses, and the Government of India gave approximately £145,000. The recurring expenses are shared equally by industry and the Government. Recently, membership of the Association was thrown open to mills all over India, and co-operative research is now increasingly made use of by the premier industry of the country.

The laboratories are on the Gujarat University campus and consist of a multi-story central block, covering an area of 100,000 sq. ft., which accommodates the library, offices and laboratories of the various research divisions, the administrative offices, the stores and precision workshop, and the services in a basement. The block is connected at one end to a single-story building which houses the pilot mill. At the other end are situated a cafeteria and an auditorium. The pilot mill is equipped with complete machinery for spinning, weaving and chemical processing, with facilities for experimenting under a variety of conditions. The physical testing laboratory has a comprehensive range of modern testing instruments for fibres, yarns and fabrics. The unit plant laboratory has a number of laboratory models of standard dyeing and printing machines and will also be equipped in the near future for some of the unit processes of chemical engineering. The entire building is air-conditioned for comfort, except for the physical testing room and the pilot mill, which have separate air-conditioning to maintain required constant temperatures and humidities.

Even though the laboratory building has only now been completed, the work of the Association commenced about five years ago in the Science College at Ahmedabad with the recruitment of staff for statistics, chemistry, physics and psychology. Recognizing the increasing importance of industrial psychology and the science of management, the Association decided from the outset to include these in its organization. It was also felt that during its early years the Association should commence its work with the utilization of existing scientific knowledge and apply this for the immediate benefit of the industry. Emphasis was deliberately placed on operational research aimed at standardization and rationalization of existing processes and work methods, and on applied research designed to introduce developments of practical use to the industry. This was done with the view of fostering scientific consciousness among those who work in the industry and creating confidence in the practical utility of applying the scientific method to the problems of industry.

Operational and applied research is generally carried out in the mills in collaboration with the technical staff of the mills. At all stages of the experiment, critical evaluation is continuously done in frequent conferences among the staff of the Association and in discussions with mill management and technicians. After the successful completion of experimental studies in two or three mills, the results are published in the form of research notes. This, however, constitutes only half the work. Successful implementation and translation of the benefits to industry are equally important tasks on which the Association has placed great emphasis. It believes it to be its duty to demonstrate without cost to its members, in their own mills, the full utility of implementation of its research work. However, every effort is made to ensure that its resources are not diverted to routine operations which legitimately fall within the domain of individual mill management. When circumstances require that the Association should be engaged in routine services, separate units are created for this purpose. In this way the Association operates routine physical and chemical testing laboratories and provides servicing and supervision of quality control, training-within-industry programmes and other management techniques to industry. The cost of these units is defrayed by the mills which participate in these benefits.

To-day the Association has eight Divisions dealing with Physics, Chemistry, Statistics, Psychology, Liaison, Technology, Library and Documentation and Administration.

Pending the establishment of the Textile Technology Division, the Physics Division mainly concentrated during the initial years on problems of spinning. It modified the micro-sample spinning technique developed in other laboratories so that a sample of one pound of cotton may be spun in a short time on the usual mill spinning plant under mill conditions of speeds, settings, etc. The yarns produced by this small-sample spinning method check well in lea strength with the yarns produced by the normal large-scale mill processes. This technique has also been used for investigating the application of various spinning aids and in the investigation of blending of cottons. A study has been undertaken of the fibre length distribution and the evenness of the material under process at various stages in spinning. This Division has a well-equipped optics laboratory in which work is being done at present on a study of the adsorption of dyes and other chemicals on the surface of textile materials. Attempts are also being made to correlate the degree of orientation of mercerized fibres with lustre and to use the X-ray technique for determining the degree of mercerization. A modest beginning in instrumentation and electronic developments has been made by creating a separate section for these in the Physics Division.

The Chemistry Division started initially with a survey of the various textile chemical processes in the member mills of the Association and the determination of optimum conditions for these processes. A detailed study of sizing practice was made, and simple experimental methods for the evaluation of sizing materials and methods were demonstrated to mills. Extensive studies were also made to assess the value of tamarind kernel-powder, an indigenous material, as a sizing material for cotton warps for both bleached and grey sorts. Suitable modifications were worked out to overcome the objectionable reddish colour of this material. A long-term fundamental study of sizing has been planned, and work on this programme has been started very recently. Attempts are also being made to produce improved finishes, using so far as possible indigenous materials. Three such processes have been worked out on a laboratory scale and will shortly be tried in mills on a pilot-plant scale. In order to explore the possibilities of mercerizing textiles made from Indian cottons, an extensive study has been undertaken on a comparison of the mercerization of different cottons (Indian, African, American and Egyptian) in fibre, yarn and cloth stages. The Chemistry Division also maintains a technical service which undertakes investigation of a number of production problems from the chemical processing departments of member mills.

The Textile Technology Division has been created this year with the arrival of machinery for the pilot mill. Among the problems that are being taken up for investigation are (1) the relationship between individual fibre characteristics of a blend and the properties of the yarn and its weavability, and (2) the effect of yarn conditioning, atmospheric conditions and loom tensions on weavability.

The main effort of the Statistics Division has been directed to the development and application of quality control methods to the textile industry. With the Association's collaboration, quality control sections have been established in about twenty-four mills, and statistical methods have been applied by these sections to improve operational characteristics such as breakages, uniformity, waste, damages and efficiency. The Statistics Division has also carried out a number of short-term experiments in spinning, including studies on the effect of mixing soft waste with cotton, the effect of vibrating bobbins, the effect of different speeds and settings in processing, a comparison of two and three passages of drawing, and an improved method of ribbon lap preparation. Theoretical studies of machine interference have also been made and are being checked with the results of actual mill working. At present the quality control technique is being extended to chemical processing. The possibility of introducing acceptance sampling is also being explored. The Division maintains a computing section to analyse the data coming from various Divisions as well as from the quality-control sections of mills; it publishes a quality-control bulletin incorporating the data collected by the various quality-control sections in mills and the results of experiments carried out by them, and conducts classes for training technicians in statistical methods.

The Psychology Division has been concerned mainly with problems of attitudes, labour management relations, supervisory training, incentives, time-and-motion studies, the effect of physical working conditions on the health of workers and their efficiency, etc. A number of interesting results have been obtained in these various fields, some of which have found practical application on a large scale in mills. A project was conducted during 1950–51 in collaboration with Prof. Gardner Murphy, Unesco consultant to the Government of India, in order to study labour-management tension within the textile industry. As a result of this study, the need for supervisory training was emphasized and training-within-industry programmes were started in 1953 to fulfil this need with the technical assistance of the International Labour Organization. Thirty-one mills are participating at present, and in the short period of one year 2,884 supervisors have been trained. The three training-within-industry programmes have been translated into the Gujerati language so that a greater number of supervisors can participate in them. At the joint request of organized industry and labour, the Psychology Division has worked extensively on assessment of work loads in the various occupations of the industry and on applying the job evaluation methods for recommending a scientific wage structure.

Recently the newly established Liaison Division has taken over, from the research divisions, primary responsibility of maintaining close contacts with member mills and the quick translation of the Association's research into routine industrial practice.

With the completion of the first five years of the Association, the need for a properly balanced research programme covering both fundamental and applied problems has been increasingly felt. Such a programme, where fundamental and applied research would complement one another and constantly provide new ideas, has now been initiated. With technical assistance from Unesco, a project for the study of the nature of macromolecules has been started. An equilibrium centrifuge and gas adsorption apparatus have been set up. Some of the other fundamental problems in this programme are the preparation and properties of colloid solutions with special reference to spinning aids; the spectrophotometric, colorimetric and chemical study of adsorption of substances on textiles; changes in the surface and mechanical properties and in the fine structure of textiles, caused by processes such as sizing, dyeing, mercerizing and finishing; the theory of tensile strength of yarns; the relation between structural geometry and mechanical properties of fabrics; and morale and attitude surveys. Along with the national laboratories of India, the Ahmedabad Textile Industry's Research Association is playing a significant part in tackling the great and important problems which face India to-day.

ABNORMAL PROPERTIES OF HISTONES FROM MALIGNANT CELLS

By Dr. H. J. CRUFT, Dr. C. M. MAURITZEN* and Dr. E. STEDMAN, F.R.S.

Department of Biochemistry, University of Edinburgh

THE main object of this article is to give a brief description of a difference which has been observed to exist between the histones of malignant and normal cells. For an appreciation of the nature and significance of this difference, however, a knowledge of the properties and behaviour of histones from normal cells is required. It is therefore proposed, before describing and discussing the results obtained with the histones from cancer tissue, to summarize the pertinent aspects of our knowledge of these proteins, much of which has not hitherto been published.

Basic Proteins of Cell Nuclei

It has long been known that proteins with pronounced basic properties are present in the sperm heads of many fishes as well as in the nuclei of calves' thymocytes and of nucleated erythrocytes, and more recent work has shown that such proteins are, in fact, widely distributed in the nuclei of animal, and probably also of plant, cells where they constitute a considerable proportion, in some cases amounting to 30 per cent, of the dry weight of the nucleus. Two types of such proteins have been distinguished, namely, protamines and histones, the former of which seem to occur only in the sperm heads of certain fishes. The best known and most investigated of the protamines are salmine and clupeine, the basic proteins present in the sperm heads of the salmon and herring, respectively. Their properties fully justify their separate classification on chemical grounds, for they are distinguished from the histones in three respects: their salts form true solutions in water; no aromatic amino-acids enter into their composition; and they possess considerably stronger basic properties due to a higher content of basic amino-acids. It is not certain if all the basic proteins which have been termed protamines exhibit these properties, for there is little information available about them, while some doubt remains about the purity of the specimens originally examined.

While justified on chemical grounds, the classification of the basic proteins of cell nuclei into protamines and histones is not warranted physiologically, for a study of their distribution indicates that they are homologous proteins. Thus, so far as they have been examined, all fish sperm heads contain a basic protein. In the salmon and herring this is a protamine. On the other hand, in the cod it is a histone. Taken in conjunction with the fact that basic proteins are present in all animal cell nuclei so far examined, this constitutes ample evidence of the identity of the functions of the two types of protein.

---

* I.C.I. Research Fellow.

Composite Nature of Histones

The older work on histones served to demonstrate the occurrence of these proteins and to establish their general nature. With the development of methods for the isolation of cell nuclei from animal tissues additional to fish sperm and nucleated erythrocytes, the examination of an extended range of histones became possible. Such work[1,2], carried out in this laboratory, revealed the fact that the basic proteins extracted directly from isolated cell nuclei contained at least two components; one present in greater amount being provisionally termed the main histone and the other the subsidiary histone. As judged by their constancy in composition after fractionation, a number of the main histones were obtained in an apparently pure state. Purification of the subsidiary histones offered more difficulty, largely because of their occurrence in smaller amount. Nevertheless, two were fractionated to a degree approaching, although somewhat short of, purity. It has since been possible to supplement this work with electrophoretic studies both on many of the earlier preparations and on new ones obtained by identical methods. The results have confirmed and extended the former conclusions. Electrophoretic analysis indicates that, with few exceptions, the unfractionated histones extracted from isolated cell nuclei consist of three components. This is illustrated in Fig. 1, where the electrophoretic diagram obtained from the total histones extracted from the nuclei of fowls' erythrocytes is reproduced. It is proposed, following the convention in use for other proteins, to term these components, in descending order of mobility, α-, β- and γ-histones. By comparing the electrophoretic mobilities of histones from various sources with those of the fractionated preparations described in earlier investigations, it has been possible to identify the α-component with the subsidiary histones previously described. The so-called main histone consists essentially of the β-component contaminated with a small proportion of γ-component.

Cell Specificity of Histones

The species specificity of homologous proteins is such a general phenomenon that it would be expected to apply without question to the basic proteins of the cell nucleus. Nevertheless, it is difficult to demonstrate chemically such specificity if proteins of the same type are compared. Thus, salmine and clupeine, the protamines of the sperm heads of the salmon and herring respectively, are extraordinarily similar in chemical composition, although it is now known[3] that there are small differences between them, the most convincing being the presence of threonine in the latter and its absence in the former. With the recognition, however, that the histone present in the sperm head of the cod is homologous with the protamines in the sperm heads of the salmon and herring, no doubt remains that the basic proteins of nuclei from the same type of cell follow the general rule.

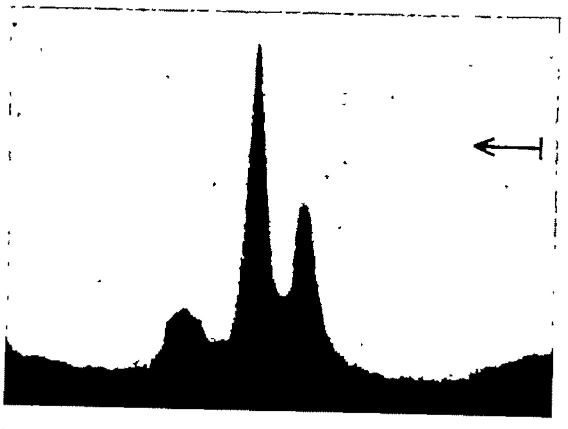

Fig. 1. Electrophoresis of total histone from fowl erythrocyte nuclei. Descending boundary; conc. 0·6 per cent; μ = 0·18; veronal buffer pH 7·6; showing α-, β- and γ-histones

In contrast to species specificity the cell specificity of proteins within a given organism has scarcely been discussed, no doubt because many of the proteins of the various types of cells exercise entirely different functions. But if the reasonable assumption be made that the nuclei in the different cells of the same species possess similar functions—an assumption which receives much cytogenetical and chemical justification—the question of the identity or cell specificity of the basic proteins of cell nuclei assumes considerable importance. For cell specificity in these proteins would imply that each protamine and histone was essential to, and possibly assisted in the control of, the particular character of the cell in which it occurred. That some protamines and histones are, in fact, cell specific has already been demonstrated. Thus, the nuclei of the erythrocytes and liver cells of the salmon contain histones in place of the protamine in the sperm head[3]. There is, moreover, some evidence that the histones in the two former types of cell differ considerably from one another in their arginine contents. The main histones in the erythrocytes and thymocytes of the fowl also differ demonstrably in their arginine contents, while the particular α-histone present in the erythrocytes of this species is entirely absent from the thymocytes[1]. It is true that the main histones from fowls' tissue upon which the analyses demonstrating their cell specificity were made were not homogeneous but, as indicated in the preceding section, consisted of mixtures of β- and γ-histones. This does not, however, invalidate the results, for it has since been found that the electrophoretically pure β-histones isolated from the main histones by preparative electrophoresis do not differ from the latter in their basic amino-acid contents. It is not yet certain if this absence of change in composition after purification is due to the relatively small quantity, which did not amount to more than a few per cent, of γ-component present in the main histones or to the very similar composition of the β- and γ-components, although some evidence, at present incomplete, supports the latter explanation. To illustrate the degree of purity attained by preparative electrophoresis, the electrophoretic diagram of a preparation of the β-histone from calves' thymus glands is reproduced in Fig. 2.

One impediment to the complete generalization of the above results on the cell specificity of histones has been the failure to detect any difference between the compositions of the main histones from the liver cells and thymocytes of the ox. It has now been found that these two β-histones possess different isoelectric points, which are at pH 11·0 and 10·8 respectively for the thymus and liver histones, and that their electrophoretic mobilities differ from one

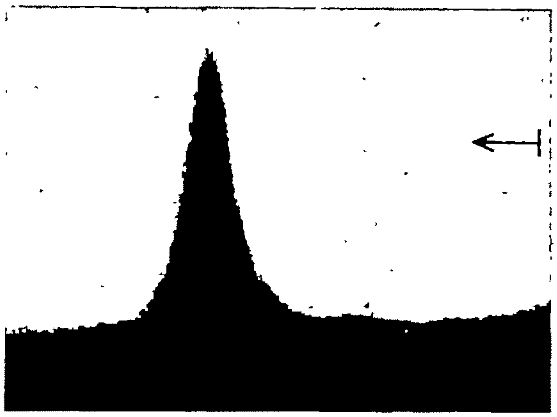

Fig. 2. Electrophoresis of pure β-histone from ox thymus nuclei. Descending boundary; conc. 0·5 per cent; $\mu = 0\cdot18$; veronal buffer pH 6·2

another over a wide range of pH[8]. These differences are outside the limits of experimental error. They are nevertheless so small as not, perhaps, to appear completely convincing, particularly as attempts to effect the electrophoretic separation of a mixture of the two histones gave inconclusive results. As will be described below, the cause of this failure has now been ascertained, with the result that no doubt remains that the β-histones from the liver cells and thymocytes are different substances. This achievement goes a long way to establishing as a generalization the former finding that the basic proteins of many cell nuclei are cell specific.

Aggregation of Histones

The key to the solution of the problem of unequivocally distinguishing between the liver and thymus β-histones of the ox was provided by determinations of the rates of diffusion of the two proteins. These measurements, which were made in the Hilger Tiselius electrophoresis apparatus, were primarily required for other purposes; nevertheless, it was hoped that they might also provide evidence of differences between the physical properties of the two histones. No such evidence was, however, obtained. On the contrary, the rates of diffusion of the two substances were indistinguishable at all pH's examined. This is evident from Fig. 3, where the diffusion constants are plotted against pH. While giving another example of the very great similarity which exists between the two histones and thus tending to suggest that they are identical, the curve in Fig. 3 is nevertheless remarkable in that it indicates not only that aggregation of the protein micelles takes place, but that this aggregation increases much more rapidly with increase in pH than is usual with other proteins. This can be better appreciated from the particle weights. When these are calculated by standard methods from the diffusion constants and the viscosities of the solutions, it is found that they increase from $7\cdot6 \times 10^4$ at pH 1·4 to 7×10^6 at pH 7·0. In other words, the particle weight at pH 7·0 is approximately 100 times that at pH 1·4.

Mixed Aggregates of Histones

The histones of the liver cells and thymocytes are clearly very closely related to one another. Their basic amino-acid and tyrosine contents are indistinguishable; their electrophoretic mobilities and isoelectric points differ only slightly; their particle weights in solution are, within the limits of experimental error, identical; and they possess the same pronounced capacity to form aggregates, which they do to the same degree and with the same dependence upon pH. This great similarity between them suggested that under appropriate conditions they might be capable of forming mixed aggregates in solution which would simulate the behaviour of a homogeneous protein. If this were the case an explanation would be offered of the failure, referred to above, to effect an unequivocal separation of a mixture of the two histones by electrophoresis in the Tiselius apparatus. The conditions used for preparing a solution of the mixture, which were identical with those employed for making the solutions for electrophoresis or diffusion experiments, were, moreover, such as to favour the formation of mixed aggregates if the molecules possessed the capacity to do this. Thus, in each type of experiment, the sulphate of the histone or histones, which itself would yield an acid solution of about pH 2·0 if dissolved in water, was dissolved in dilute hydrochloric acid and the solution brought to a less acid pH by dialysis against the appropriate buffer for a period of about three days. By this procedure the histone was changed slowly from an unaggregated or little aggregated form to that characteristic of the final pH of the solution. Every opportunity was thus provided for the formation of mixed aggregates when two histones were used.

With the object of submitting the above suggestion to experimental verification, it was postulated that if separate solutions of the two histones at the same pH and in a highly aggregated form were mixed, the formation of mixed aggregates would either not take place at all or would only do so extremely slowly. In either case, it should be possible to effect their separation from the mixture by electrophoresis. Tests of this postulate with artificial mixtures of the β-histones from ox liver and thymus glands have not only resulted in its verification but also have simultaneously conclusively demonstrated that the two histones are different compounds. This is illustrated

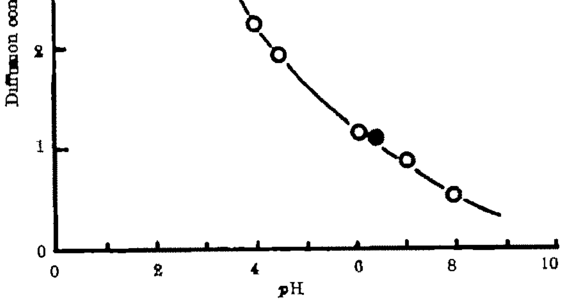

Fig. 3. Graph of diffusion constant against pH, for ox thymus and ox liver β-histones; conc. 0·5 per cent; $\mu = 0\cdot2$; veronal-HCl buffers

Ox thymus β-histone, ○; ox liver β-histone, ●

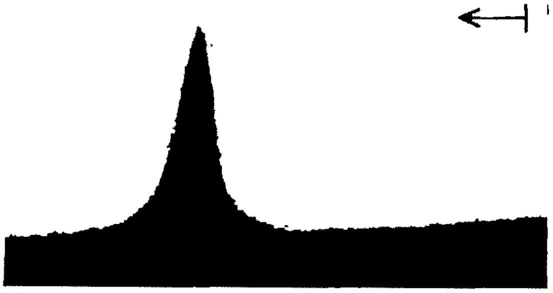

Fig. 4. Electrophoresis of an artificial mixture of ox thymus and ox liver β-histones, solution of the mixture dialysed for 60 hr., conc. 0·6 per cent total; $\mu = 0·18$; veronal buffer pH 8·6

in Figs. 4 and 5, which give electrophoresis diagrams for mixtures of liver and thymus histones dialysed together and separately at *p*H 8·7. A similar separation was obtained at *p*H 6·7. Other experiments have shown that mixed aggregates are formed with both dialysis procedures when the *p*H of the buffer is between 4·0 and 5·0. As can be seen from Fig. 3, this corresponds with the *p*H at which a rapid increase in aggregation commences. It is thus evident that below *p*H 5·0 aggregation is too small and perhaps too labile to prevent the formation of mixed aggregates on mixing solutions of the two histones.

Another example of the formation of mixed aggregates between different histones will be recorded below. Whether it is a general phenomenon among histones or whether it is confined to very closely related histones is not yet known. It is possible that it may even occur between histones and other proteins, and thus account for the power of histones to precipitate other proteins from solution.

The Histones of Malignant Cells

The investigation of the nature and properties of the components of normal cell nuclei which has been in progress in this laboratory for more than twelve years has been carried out not only for its own intrinsic interest, but also because it seemed to be a necessary preliminary to an examination of the characteristics of the nuclei of malignant cells. Some malignant cells have, nevertheless, occasionally been examined concurrently with this work on normal cells, particularly when suitable cancer tissue has become available. But in the absence of detailed information about the nature and functions of the components of the nuclei of normal cells, such investigations have necessarily been somewhat restricted in scope.

The earliest work[4] of this kind indicated that the nuclei of malignant cells differed from normal cell nuclei in containing a much smaller amount of histone. Similar results have since been obtained by Debov[5], and further examples have also been encountered in this laboratory. Thus, the nuclei from a human breast sarcoma yielded only 4 per cent of their dry weight of histone sulphate as compared with a yield of 25–30 per cent from many normal cell nuclei. Similarly, in work to be discussed below in another connexion, the nuclei from an induced rat hepatoma gave only 14·8 per cent histone sulphate. Nevertheless, such great deficiencies in histone do not appear to be characteristic of all cancer tissue, for, while high contents have never been observed in nuclei prepared from such material, figures which approach the normal value have occasionally been obtained. This was the case, for example, with a human bronchogenic carcinoma, the nuclei of which yielded 20·5 per cent of their dry weight of histone sulphate. In view of this result it appears probable that the low content of histone in the nuclei of many malignant cells is a result rather than a cause of their abnormal nature.

A new approach to the cancer problem became possible with the discovery that histones are cell specific. As an expression of the possible physiological meaning of this remarkable phenomenon, the hypothesis was advanced[1,2] that these basic proteins function in the nucleus as gene inhibitors, thus maintaining, if not wholly determining, the character of the cells in which they are present. It was implicit in this hypothesis that a change in the properties of the histone present in a cell would result in a change in its character, so that the transformation of a normal into a malignant cell would necessarily be associated with a change in the histone which it contained. Histones from both human cancers and experimental tumours have therefore been examined from this point of view.

In the first phase of the work, material accumulated by Stedman and Stedman during the course of their earlier studies was mainly used. This consisted of the β-histones obtained from the nuclei from: (1) the lymph glands in a case of human lymphatic leukæmia, (2) a human bronchogenic carcinoma, (3) a human breast sarcoma, (4) the Walker rat carcinoma, (5) the mouse carcinoma 2146, and (6) the *Rb*3 transplantable rat sarcoma induced by dibenzanthracene. All these histones were found to differ markedly from those from normal tissues in two respects. They proved to be much less soluble, and to possess considerably smaller electrophoretic mobilities than normal histones. These divergences are well illustrated by the behaviour of the histone from the case of lymphatic leukæmia. When a 0·5 per cent solution of the sulphate of this histone in dilute hydrochloric acid is dialysed against a veronal buffer above a *p*H of 4·6 for several days, a precipitate of the histone forms in the solution. The precipitation is complete at *p*H 7·0 and nearly so at *p*H 5·0. In contrast to this behaviour, histones from normal tissue such as

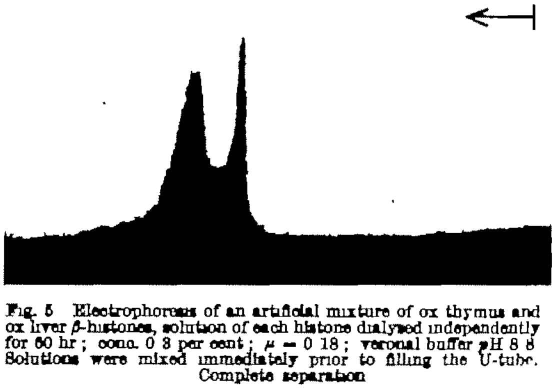

Fig. 5 Electrophoresis of an artificial mixture of ox thymus and ox liver β-histones, solution of each histone dialysed independently for 60 hr; conc. 0·3 per cent; $\mu = 0·18$; veronal buffer pH 8·6. Solutions were mixed immediately prior to filling the U-tube. Complete separation

ox liver and thymus glands, fowl erythrocytes and mouse spleen and liver, exhibit no tendency to precipitate under the same conditions until a *p*H of about 10·0 is reached, that is, one approaching their isoelectric points. It is true that normal histones show an increased Tyndall effect, indicative of an increase in aggregation, with increasing alkalinity; but this effect is present in the tumour histones in much more acid solutions. The insolubility of the leukæmic histone necessarily restricts the *p*H-range over which its electrophoretic mobility can be measured. Nevertheless, in the range below *p*H 4·6, where such determinations are possible, its mobility falls with increasing *p*H very much more rapidly than is the case with normal histones. The *p*H-mobility curve appeared, in fact, to suggest that its isoelectric point is in the region of *p*H 7·0. Similar solubility and mobility effects, although sometimes somewhat less marked, were observed with the other abnormal histones[8].

The above results show that the physical properties of histones from malignant cells exhibit pronounced differences from those of normal cells. There is presumably an underlying chemical cause of these differences; but its nature has not yet been ascertained. Analytical results do not suggest that deficiencies in basic amino-acids are involved. Many features of the abnormalities could, however, be explained by an increased content of acidic amino-acids; but a further discussion of this point must await its experimental verification.

There is one respect in which the above experiments fall short of the ideal: no direct comparison was made between the histone from a malignant cell and the cell type from which it originated. It is true that, in the course of this investigation, the histone from human thymocytes has been found to exhibit a normal behaviour with respect both to solubility and electrophoretic mobility; but it might be argued that the thymocyte was of a different cell type from the lymphocyte. It was therefore deemed advisable to repair what might be regarded as a defect in this work.

For this purpose malignant hepatomas were induced in rats by the well-known method of including 3′-methyl-4-dimethylaminoazobenzene in their diets. After the tumours became palpable they were allowed to grow for 10–14 days or until the animal became moribund, whichever was the shorter period.

As the growth of the tumours had proceeded to different degrees in the individual rats, they were divided into two groups according to their weight. Those weighing between 15 and 20 gm. were termed early stage tumours, while the larger ones, weighing between 40 and 90 gm., were described as fully developed tumours. The cell nuclei were prepared separately from the two groups as well as from normal rat livers by our general methods[4], and the histones extracted from them by our normal procedure[3]. Without any purification by fractionation, all three preparations surprisingly proved to be electrophoretically homogeneous. It is certain, from their behaviour and properties, that they are not α-histones, but it is impossible at present to decide whether they are β- or γ-histones, although they are presumed to be the former.

In conformity with the behaviour of the other tumour histones, that from the fully developed rat hepatoma possessed a solubility of less than 0·5 per cent in a veronal buffer at *p*H 5·8. In other words, on dialysing a 0·5 per cent solution of the histone in dilute hydrochloric acid against the buffer, a considerable proportion of it was precipitated from the solution. On the other hand, the histone from the normal rat livers, when treated in precisely the same way, formed no precipitate, nor did it do so when the *p*H of the buffer was increased to about 8·5, the greatest alkalinity tested. The electrophoretic mobilities of the two histones, reproduced in Fig. 6, also differed, the hepatoma histone showing the rapid fall in mobility with increase in *p*H which characterized the other tumour histones. Not only do these histones differ, however, in physical properties. Quantitative determinations of their basic amino-acid contents show that they also differ significantly in their lysine and arginine contents.

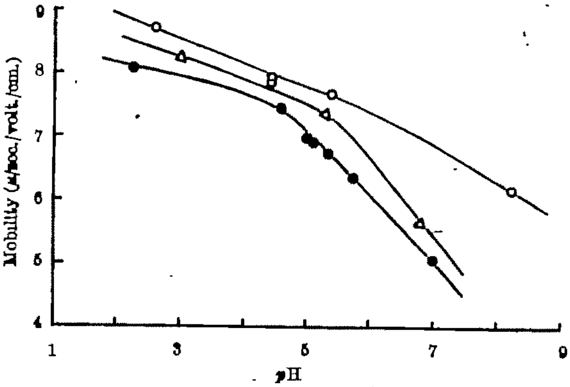

Fig. 6. Mobility – *p*H curves for rat liver histones conc. 0·1–0·5 per cent; $\mu = 0{\cdot}18$; veronal buffers.
Normal rat liver histone, ○; early stage rat hepatoma histone, △; fully developed rat hepatoma histone, ●

While thus giving confirmation of the earlier results, the experiments with the rat hepatomas presented one feature which was at first puzzling. The histone from the early stage hepatoma, although electrophoretically homogeneous, exhibited properties which, as is evident from Fig. 6, were intermediate between those of the other two. In default of any better explanation, this would imply a continuous change in the properties of the histone during the growth of the tumour, despite the contradiction inherent in this implication. A better explanation can, however, be given. Although care was taken to remove normal liver tissue from the early stage tumours, this tumour tissue would undoubtedly still contain a moderate proportion of normal liver cells. As a result, the histone isolated from it would originate partly from hepatoma and partly from liver cells. If the two histones from these different cells then formed mixed aggregates in the manner demonstrated above for ox liver and thymus histones, the product would be electrophoretically homogeneous with a mobility intermediate between those of the two components. In support of this explanation it has been found that a mixture of normal rat liver histone and the histone from the fully developed hepatoma dialysed together at *p*H 5·0 or 6·8 does, in fact, simulate the electrophoretic behaviour of the histone from the early stage hepatoma. But when they are dialysed separately at *p*H 7·25, a procedure which necessarily has to be carried out at the low concentration of about 0·14 per cent for each histone, and then mixed, separation of the components occurs on electrophoresis as with the thymus and liver histones of the ox.

Two main conclusions may be drawn from the above work on malignant cells: (1) the histones present in the nuclei of such cells are, like those of normal cells, cell specific; (2) the histones of cancer cells are characterized by solubilities and electrophoretic mobilities which are smaller than those of normal cells. These effects are associated with their greater ability, as shown by their small diffusion constants, to aggregate in solutions more acid than neutrality.

The results also support the hypothesis that histones function as gene inhibitors. It is not proposed, however, to discuss either this point or its obvious implications, for it is clear that, while the results accord with the hypothesis, they do not give final confirmation to it. But it is perhaps not out of place to point out that this work constitutes the first occasion on which a characteristic and qualitative difference has been shown to exist between a known cell component isolated from malignant cells and that obtained from normal cells.

One observation made during the course of this investigation, although it does not form part of the main theme of this article, seems of sufficient importance to be mentioned by way of a postscript. As pointed out by Miller and Miller[7], when rats are fed 3′-methyl-4-dimethylaminoazobenzene, the dye becomes bound to the liver proteins. This binding reaches a maximum in a month and thereafter slowly and continuously diminishes. In the present work, nuclei were isolated from the livers at this particular period and examined. They were found to contain dye. Nevertheless, the histone extracted from the nuclei was completely free from dye, which remained bound to the nuclear residue. If Miller and Miller's statement that deoxyribonucleic acid does not bind the dye is correct, it follows that it must be bound by chromosomin. It is thus possible that the first stage of its carcinogenic action is its attachment to the protein of the chromosomes.

We acknowledge with thanks the receipt of a grant from the Department of Health for Scotland which has defrayed part of the expense of this investigation.

OBITUARIES

Dr. H. A. Lafferty

HENRY ALOYSIUS LAFFERTY was born at Ardstraw, Co. Tyrone, on May 10, 1891. His early education took place at the local National School; at St. Columb's College, Londonderry; and at the Christian Brothers School, Omagh. He entered the Albert Agricultural College, Glasnevin, in 1908, and in the following year was awarded an agricultural scholarship into the Royal College of Science, Dublin. On receiving his diploma of the latter institution in 1912 he became a research scholar under Dr. Pethybridge, and later was appointed assistant in the Seeds and Plant Disease Division. He held this post until 1921 and was then appointed junior agricultural inspector. On Dr. Pethybridge's resignation in 1923, Lafferty became head of the Seed Testing and Economic Botany Division of the Department of Agriculture, Republic of Ireland, a post which he held until his death.

Lafferty collaborated with Pethybridge for a number of years on investigating potato diseases in the west of Ireland; but he is best known in the plant pathological world by his contributions to our knowledge of flax diseases, in investigations of which he played an important part.

During the First World War flax became an important crop, as linen was then in high demand for aeroplane construction, and foreign sources of raw material were cut off. Scarcely anything was then known about diseases of flax, and the incidence of failures, or partial failures, of this crop due to disease was common. Pethybridge appointed Lafferty to investigate this problem, and no more suitable choice could have been made. Coming from a farming community situated in the centre of a big flax-growing district, and from a family which from the early years of the nineteenth century had been engaged, first, in processing flax and later as flax buyers, Lafferty was familiar with this crop in all its cultural stages and in its preparation for spinning. This knowledge, together with his training in plant pathology, made him the ideal research worker for the job. As a result, during the period 1917–22, all the major maladies of flax in these islands were fully described and the life-history of each of the causal organisms investigated. The published reports of these researches were not only of scientific but also of economic value.

Besides the reports on investigations on flax diseases, Lafferty was joint author with Pethybridge on maladies of potato, tomato and apples, and his scientific investigations gained him the fellowship of the Royal College of Science in 1923, and afterwards the degree of D.Sc. of the National University in 1938.

As head of the Seed Testing Station from 1923 onwards, his duties left Lafferty little time for investigation of plant diseases. The knowledge of these, however, proved invaluable to him in his new post, and especially so as no plant pathologist was attached to the Seed Testing Station. Although severed from practical investigations, Lafferty never ceased to take an interest in plant pathology, and at the International Seed Testing Congress in Rome in 1928, he spoke on the importance of seed-borne diseases—an international problem which is attracting considerable attention at the present time.

He was very successful in his administration of the Dublin Seed Testing Station, and he took a personal interest in every one of his staff. Among the seed merchants he was held in the highest esteem, while the farming community will always be indebted to him for his endeavours to improve the quality of agricultural seeds sold in Ireland. Lafferty published a number of articles relative to seed testing in the *Journal* of the Department of Agriculture, Dublin, and he was a regular contributor to reports of the International Seed Testing Association.

Recognition of his work was shown by his unanimous selection as president of the International Seed Testing Association in Washington in 1950. His retention of this position each year since was a tribute to the efficiency and courtesy with which he carried out his duties. These culminated in his very successful organization of the Society's International Congress held in Dublin in May 1953.

As a debater at meetings, Lafferty had few equals and his personality was outstanding. Following a chat with him in the ordinary course of work, one always came away stimulated.

A few years ago Dr. Lafferty suffered a serious illness. Although afterwards he resumed duties, he never fully recovered his health. Then in 1953 he had a relapse, yet was again back at the Seed Testing Station in June 1954; but his return was of short duration as he soon suffered a further relapse, and he died on July 19. He was predeceased by his wife some years ago, and he is survived by two sons for whom the greatest sympathy is felt. R. McKay

Dr. W. E. Foster

Dr. W. E. Foster, who died on August 3 as a result of a motor-cycle accident, was lecturer in botany in the Durham Colleges, University of Durham. Apart from the period 1945–49, when he was an I.C.I. Fellow, he had held this appointment since 1940, when he went to Durham from King's College, Newcastle upon Tyne. He had done much work on the physiology and biochemistry of respiration, including studies of carbon dioxide zymasis; recently he had been engaged in work on physiological ecology with special reference to the oxygen supply and respiration of marsh plants. He was a gifted lecturer and an inspiring teacher; and his untimely death at the age of forty-three is deeply regretted by his many pupils, as well as by his friends and colleagues.

NEWS and VIEWS

Chemistry at Dundee: Prof. A. D. Walsh

Dr. A. D. Walsh, who is to succeed Prof. D. H. Everett (see *Nature* of March 20, 1954, p. 523) in the chair of chemistry at Queen's College, Dundee, is thirty-eight years of age and since 1949 has been successively lecturer and reader in physical chemistry in the University of Leeds. He received his undergraduate training in Cambridge, entering Corpus Christi College as an Open Scholar in 1935. His first research (with Dr. W. C. Price) was concerned with the measurement of the far ultra-violet absorption spectra of simple molecules, from which it is possible to compute their ionization potentials. More recently Dr. Walsh has greatly extended the range of his investigations in this field in a manner which has added very considerably to our knowledge of molecular structure. During the War his attention was directed to chemical processes occurring in internal combustion engines. From this work his interest naturally extended into the field of spontaneous combustion. Both in the fields of spectroscopy and of combustion Dr. Walsh has made distinctive and original contributions and, because of his capacity for lucid exposition, has been greatly in demand as a lecturer both in Britain and overseas. Although his departure is a serious loss for chemistry at Leeds, he will take with him to Dundee the good wishes of his colleagues and friends for success in his new post.

J. L. Proust (1754–1826)

One of the architects of modern chemistry, Joseph Louis Proust, was born in Angers two hundred years ago, on September 26, 1754. He began his chemical studies in his father's apothecary's shop and later became chief pharmacist to the Salpêtrière in Paris. In 1784 he made one of the first man-carrying balloon ascents with J. F. Pilâtre de Rozier, in whose *musée* he gave lectures on chemistry. From Paris he went to Spain, teaching chemistry at the artillery school in Segovia, and later at Salamanca. He served as director of the royal laboratory in Madrid during 1789–1808, when the Peninsular War ruined his career and the invading French army destroyed his laboratory and collections. It was in Madrid that his greatest and most enduring work was done. The period 1799–1807 witnessed his prolonged and bitter controversy with Jean Claude Berthollet. With brilliant analytic skill and logical reasoning, Proust pointed out some of Berthollet's errors, showed that chemical combination occurs only in fixed proportions by weight, and thereby established the law of definite chemical proportions. In 1805 he demonstrated the presence of dextrose in various natural products, and he discovered leucine in 1819. Receiving a pension from Louis XVIII, he retired to Craon in Mayenne, was elected to the Paris Academy of Sciences in 1816, and finally returned to the town of his birth, where he died on July 5, 1826, aged seventy-two.

Fire and the Atom Bomb

Fire Research Bulletin No. 1, entitled "Fire and the Atomic Bomb", by D. L. Lawson (pp. 30. London: H.M.S.O., 1954; 2*s*. 6*d*. net), deals specifically with the starting of fires by an atomic explosion and is based on a series of lectures arranged by the Home Office in May 1952 for senior fire officers and senior members of civil defence organizations. The report is written in a semi-popular style, and detailed analyses are omitted with the expressed hope that the report will be technically within the reach of a wide circle of readers. Nevertheless, it is not for the layman, and furthermore, since it is based on the official information contained in "The Effect of Atomic Weapons" (U.S. Department of Defense and U.S. Atomic Energy Commission: McGraw-Hill Book Co., 1950) and thus only on the very earliest of atom bombs, it will lose much of its interest even for those qualified to understand its details. The governing principle, as expected, is not to try to prevent all fires as a result of an atomic explosion, but to aim at reducing the fire danger to a minimum. It is important, therefore, to realize that about one-third of the energy of the bomb is released as heat radiation and that the fire danger occurs in the second flash period lasting for about three seconds, during which the bomb gives off an amount of heat equivalent to approximately 7×10^{12} calories. Accordingly, the first half of the report discusses in some detail radiation as a mode of heat transfer, the ignition of materials by an atomic flash and the physiological effect of heat radiation. In the latter half, concerned with fire prevention, attention is directed to fires started by radiation coming through windows. First, inflammable materials inside a room must be kept outside the danger zone and, secondly, the heat radiation must be prevented as far as possible from entering the room by, for example, fixing some incombustible board across the window space. Any board opaque to light radiation will also form a barrier to the heat, and various means of cutting off the radiation without obscuring the daylight are mentioned.

Formation of Plates of Grey Tin

In a brief communication to the *Proceedings of the Koninklijke Nederlandse Akademie van Wetenschappen* (57, 79, Jan./Feb.; 1954), L. J. Groen and W. G. Burgers report an important development in that they have been successful in obtaining the first compact pieces of grey tin, about 1 mm. thick and with a surface area of about 25 sq. mm. Previously, grey tin has been obtained only in powder form. From their experiments, the authors judge that the essential conditions for the preparation of the compact form are the use of thin sheets of white tin from which the grey tin is formed, a slow rate of transition and the growth of only one grey tin nucleus. The thin sheets enable the grey tin to extend in volume without splitting too soon under the stresses due to its extension; slow growth, attained by cooling to − 8° C. instead of the usual − 50° C., and starting at one point in the white tin favour a uniform formation of the grey phase. The purity of the white tin used, which in the authors' case was not less than 99·99 per cent, also has an influence. Compact pieces of grey tin were obtained starting with both polycrystalline material and with single crystals. In one instance, starting from a single crystal, a grey single crystal was formed, and a Laue transmission photograph of this single crystal is given in the report.

"Philips Serving Science and Industry"

The technical reports of Philips Industries, Ltd., are well known to the scientific world for the publication of original scientific papers of high merit and often of considerable importance. The series, now terminated, on "Electronic Measuring Instruments", which described new Philips instruments and their applications, was not, however, so well known. A new series has recently been started, known as "Philips Serving Science and Industry" (1, No. 1; 1954. Pp. 32; Eindhoven: N. V. Philips' Gloeilampenfabrieken. 25*s*. per volume of six numbers), and this, as its title implies, has broader terms of reference. In addition to the instrumentation covered by its predecessor, it is designed to deal generally with the engineering and other technological developments of the company and is to be issued monthly by the Industrial Products Division. The first number contains articles on dielectric heating in woodwork fabrication and on a rectifier installation in the water purification plant for Rotterdam; in addition there are contributions on instruments, which comprise vibration recorders, oscilloscopes and the 75-kV. electron microscope. The articles are technical, but the treatment is elementary so that the non-specialist will find the material easy to read and understand.

Impregnation of Small Friable Objects

In the *Museums Journal* for August, Mr. E. Martin Burgess, of the Department of Egyptology, University College, London, describes an inexpensive vacuum tank for impregnating small friable objects. Up to the present, the method has only been used with polyvinyl acetate dissolved in toluene; but it could probably be used with as good results with 'Bedacryl' or other similar strengtheners. Polyvinyl acetate solution may be painted or sprayed on objects; but the solutions must be weak to achieve sufficient penetration. This tends to produce an undesirable glossy surface, and although this may be removed by toluene, a weakening of the surface of the object results. Total immersion produced better results; but it was still doubtful whether full impregnation had been achieved. The only really satisfactory method is to place the object in a sealed chamber containing the strengthening solution and to pump out the air. For this purpose a vacuum desiccator can be used and evacuated with a water pump if some form of trap is placed between the pump and desiccator to prevent water from getting into the solution on release of the vacuum.

Books on Agriculture and Horticulture

The third edition of "Books on Agriculture and Horticulture" has recently been published (H.M.S.O. Bull. 78. 3*s*. net). Though, according to the subtitle, this list is "Selected" (and compilers of select lists will always meet their critics), it is misleading, for no matter how concise or how comprehensive a book-list aims at being, there is no excuse for including books which can be shown to be out of print, or excluding definitely acknowledged texts. This list errs in both ways. Far too many out-of-print books are included, though since some of them may be available in libraries their appearance in such a list as this may be justified; but not when other more up-to-date books are omitted. The books are also classified according to subject; even here it is difficult in certain cases to see on what basis the compiler fits a book into a certain section. Since this list is "prepared by the Ministry of Agriculture and Fisheries" it carries the weight of authority; the compiler should therefore have taken care to ensure that his selection is at least up to date. Inquiries from publishers would have given all the information required for sifting and selecting.

A Game Reserve

The reasons why the Mijeti area in the north-west corner of the Chikwawa district of Nyasaland has been chosen as a possible game reserve by the Fauna Preservation Society of Nyasaland are explained in the latest issue of *Oryx* (2, No. 5; August 1954). The country is rough and wild and has both advantages and disadvantages. One disadvantage is that it would be difficult to attract visitors since they would be unable to see the animals, even when it becomes possible to construct roads through the area. A great advantage is that the area now affords considerable protection from poaching. The main difficulty, however, is to keep the many active animals within the area because of the lack of water during years of poor rainfall. In 1950 the Fauna Preservation Society of Nyasaland approached the Government to see if Mijeti could be declared a game reserve. The shortage of water was admitted to be a serious difficulty, and the Government would only agree to give the Mijeti the status of a non-shooting area, until it could be proved that the game could be kept all the year round within its boundaries. Faced with this challenge, the Nyasaland Fauna Preservation Society decided to do everything within its powers to meet the demand for water, and funds were voted from meagre resources for the building of dams and otherwise improving supplies. Some of these dams have already been constructed and are serving their purpose; more are to be built during the coming dry season.

Welwitschia mirabilis

In a brief but factually rich paper entitled "*Welwitschia mirabilis* Hook. F. from Seed to Seed in the Botanic Garden of the University of Stellenbosch, C.P.", H. Herre has given new and interesting information concerning this remarkable plant (*J. South Afric. Bot.*, 22, I, 23; 1954). In and near Angola, where the species occurs, it is stated that plants are not at all rare; also, farther to the north, plants are to be found growing freely among grasses and small bushes and are not necessarily confined to desert-like areas. H. Herre states that the local inhabitants use the dry parts of the leaves for fire-making and the bigger stems as chairs. The plants typically grow in old river beds and may develop very extensive root systems, up to 60 ft. long. Young plants apparently depend on mists for their main supply of moisture. The plants are exceedingly slow in their growth and it is estimated that very large specimens, with a stem diameter of 10–15 ft., may well be as much as a thousand years old. Some twenty-five years ago seeds were first germinated in the Stellenbosch Botanic Garden. It was observed that seedlings, immediately on germination, form a long tap-root and two cotyledons. The cotyledons are followed by two leaves; these persist throughout the life of the plant and are, in fact, the only leaves the plant ever has. They wear away at the tips and are constantly renewed by growth at the leaf-base. The flowers, which are dioecious, are produced annually. Under Stellenbosch conditions, twenty-three years elapsed before the first (female) flower appeared. Some details of the floral development and pollination are given, a brown bug being the agent of pollination in the plant's natural habitat. The paper is illustrated by some good photographs.

Vegetative Proliferation in Grass Spikelets

THE proliferation of spikelets in grasses other than those races which are habitually viviparous, and the factors which induce proliferation under experimental conditions in *Cynosurus cristatus* and other species, have been discussed by P. R. Wycherley (*Ann. Bot.*, N.S., 18, Jan. 1954). It is concluded that the evidence favours the hypothesis that in the viviparous races a considerably greater minimal concentration of the putative flowering hormone is required for flower induction than for culm initiation, whereas in the seminiferous races this difference is not so great. In the viviparous races, the threshold for flower initiation is rarely exceeded so that perfect flowers appear only occasionally, while in the normally seminiferous races the conditions arise only rarely where an amount of hormone is produced sufficient to initiate culms but insufficient to promote flowering.

Fuel Research Board: Report for 1953

IN these days when public attention is being focused from many directions on questions relating to fuel, its use and misuse, the report for 1953 of the Fuel Research Board with the report of the Director of Fuel Research (pp. 68 + 4 plates. London: H.M.S.O., 1954; 2*s*. 6*d*. net) is particularly opportune. One of the fields of misuse became the subject of public attention as the result of the persistent and highly polluted fog experienced in London in December 1952, and as a result the Government instituted a special inquiry into the broad aspects of the problem of atmospheric pollution and the preventive measures necessary to abate its effects on health and property. (No. 95 of "Reports on Public Health and Medical Subjects", which deals with the great fog of December 1952, has now been published; pp. 61 (London: H.M.S.O., 1954); 2*s*. 6*d*. net.) In the report of the Fuel Research Board will be found many references to the nation-wide surveys of pollution and to the research work which has been prosecuted by the Board for some time into the problems involved. It is opportune, too, that there should be recognition that these matters have not been neglected, and that, in addition, the problem is associated with the work of many other organizations—indeed, with the daily work of almost everyone who is concerned technically with the use of fuel of any type. Most interesting is the statement that the work on the programme of domestic heating has become intensified, for nearly one-half of the pollution by smoke arises from the use of coal in household grates, and this aspect of smoke pollution involves the most difficult problems in the application of preventive measures. Many other fields of fuel research are dealt with in the report, including work on the chemical and physical examination of coal, carbonization, gasification, the synthesis of oil and chemicals from coal, fuel oils, boilers and steam-raising, and the combustion in the coal-fired gas turbine; indeed, the multitude of activities must involve considerable co-ordination with other more specialized organizations also dealing with these aspects of fuel research.

Bibliography of Colour Television

THE Television Society has recently published a most useful "Bibliography of Colour Television" (pp. 16; from the Television Society, 164 Shaftesbury Avenue, London, W.C.2; 1954; 2*s*. 6*d*. post free), which was prepared in November 1953 by Mrs. K. Bourton, librarian of Ultra Electric, Ltd., and circulated among members of the radio industry. The bibliography is divided into two sections: optical and electrical. The former starts with a reference to a paper by J. Clerk Maxwell, "On the Theory of Compound Colours and their Relation to the Colours of the Spectrum" (*Phil. Trans. Roy. Soc.*, 1860), and continues with sixty-eight references to papers and books published up to 1952. The electrical section contains 313 references to papers and books, arranged in chronological order from 1934 to 1954. A list of abbreviations used and an alphabetical list of authors are included. This brochure should prove most useful to all those engaged in the science and future development of colour television.

Fourteenth Congress of Pure and Applied Chemistry, Zurich

THE Fourteenth International Congress of Pure and Applied Chemistry will be held in Zurich during July 20–28, 1955, under the presidency of Prof. P. Karrer (Zurich). At the same time, during July 21–27, the opportunity will be taken to hold the Eighteenth Conference of the International Union of Pure and Applied Chemistry, under the presidency of Prof. A. Tiselius (Uppsala). Further information regarding the Conference can be obtained from Prof. R. Delaby, 4 Avenue de l'Observatoire, Paris 6e. The Congress will be concerned exclusively with pure and applied organic chemistry and has been provisionally subdivided into three main sections: theoretical and physical organic chemistry (molecular structure, stereochemistry and reaction mechanisms); natural products (aliphatic and alicyclic compounds, including terpenes and steroids, carbohydrates, amino-acids, aromatic and heterocyclic compounds, alkaloids and glycosides); and synthetic, industrial and analytical organic chemistry (dyestuffs, plastics, tanning agents, synthetic resins, and synthetic and analytical methods). Those wishing to read papers (10–20 min. duration) must send a short summary before February 1955. All inquiries relative to the Congress should be directed to the Secretary-General, XIVth International Congress of Pure and Applied Chemistry, Zurich 1.

Autoradiography Course at Harwell

A SPECIAL course on autoradiographic techniques will be held in the Isotope School, Harwell, during December 13–16 under the direction of Dr. S. R. Pelc, of Hammersmith Hospital, London. Lectures will be given on the theory of the photographic process; photographic action of electrons; estimation of radiation damage; calculation of concentration of tracer necessary to produce autoradiographs; biological results of investigations using autoradiographic techniques; and design of autoradiographic experiments. Demonstrations will include the squashing technique applied to bean roots grown in phosphorus-32; stripping film technique; autoradiography using stripping film technique; and use of phase-contrast microscope. Practical work will include squash preparations for autoradiography, for example, bean root; autographs of sectioned material using stripping film technique; and processing and staining of autoradiographs using normal and phase-contrast microscopes. The fee for the course is £8. Accommodation in local inns can be arranged if required. Applications should be made to the Isotope School, A.E.R.E., Harwell, near Didcot, Berkshire.

Water Pollution Research Laboratory: New Premises

ON October 1 the Water Pollution Research Laboratory will move from its temporary premises in Watford, Birmingham and elsewhere to a new permanent building in Elder Way, Stevenage, Herts; it is not likely that an official opening will take place before the spring. The new premises include a three-story block, containing administrative offices, an information section and microbiological, chemical and physical laboratories. There are also four pilot-scale laboratories and facilities for building larger experimental plant in the open. Special facilities have been provided for experimental work on the treatment of sewage and industrial wastes, including a radiochemical section which will be concerned at first particularly with problems of disposing of radioactive liquids. Two of the pilot laboratories are designed for experiments on the effect of pollution on fish; this work is carried out in collaboration with a team of biologists of the Ministry of Agriculture and Fisheries.

The Night Sky in October

FULL moon occurs on Oct. 12d. 05h. 10m., U.T., and new moon on Oct. 26d. 17h. 47m. The following conjunctions with the moon take place: Oct. 5d. 24h., Mars 4° S.; Oct. 19d. 04h., Jupiter 2° N.; Oct. 26d. 23h., Venus 3° S. In addition to these conjunctions with the moon, Jupiter is in conjunction with Uranus on Oct. 8d. 04h., Jupiter being 0·4° S.; Mercury is in conjunction with Saturn on Oct. 9d. 11h., Mercury 5·6° S., and again on Oct. 24d. 11h. when Mercury is 4·7° S. Mercury, an evening star throughout most of the month, sets too soon after the sun to be observed. Venus sets about forty minutes after sunset at the beginning and middle of the month and about the time of sunset at the end of the month, and will not be favourably placed for observation. Mars, an evening star, sets about 22h. 10m. during the month, but it lies rather low for good observation in the British Isles. Jupiter rises at 23h. 20m., 22h. 35m. and 21h. 40m. at the beginning, middle and end of the month, respectively, and will be conspicuous in the constellation Cancer, its stellar magnitude varying from −1·7 to −1·8. Saturn sets at 18h. 45m. and 17h. 55m. on October 1 and 15, respectively, and is in conjunction with the sun early in November; throughout most of the month it is unfavourably placed for observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Oct. 15d. 01h. 40·8m., 33 Taur. (*R*); Oct. 15d. 23h. 35·7m., 99 Taur. (*R*); Oct. 16d. 04h. 45·5m., 103 Taur. (*R*); *R* refers to reappearance. The Orionid meteor shower attains its maximum about October 20–23; the radiant of this shower is close to γ Geminorum.

Announcements

WE regret to announce the death of Dr. André Donatien, *correspondant* for the Rural Economy Section of the Paris Academy of Sciences and *chef de service* of the Pasteur Institute of Algeria, on August 10, aged sixty-four.

MR. H. S. TASKER has been elected a Fellow of the Institute of Metals, in recognition of his distinguished services to the Institute; the total number of Fellows is limited to twelve. Mr. Tasker was president of the Institute during 1950–51, and has been chairman of its Finance and General Purposes Committee (1940–44) and honorary treasurer (1945–47).

THE French Metallurgical Society will, as in former years, hold its "Journées Métallurgiques d'Automne" in Paris during October 25–30. Further information can be obtained from the Société Française de Métallurgie, 25 rue de Clichy, Paris 9e.

THE dates of the meeting of the Meteorologische Gesellschaft in Hamburg, to be held in Hamburg in honour of the centenary of the birth of G. Hellmann (see *Nature*, May 15, p. 896), have been changed to October 8–11.

THE Swiss Federal Commission for studying Hail Formation and Hail Prevention will hold an international symposium on experimental meteorology at the Swiss Federal Institute of Technology, Zurich, during October 4–6. The symposium will discuss primarily the question of the natural processes of rain and the methods of influencing it, as well as the problem of the formation of hail and its possible prevention. Further information can be obtained from the president of the Commission, Prof. R. Sänger, E.T.H., Postfach, Zurich 23.

ISSUED annually, with some interruptions, since 1915, the "Subject Index to Periodicals" is now being published quarterly with annual cumulations. The first of these quarterly issues covers January to March 1954 (pp. 71. London: Library Association), and the three hundred British periodicals indexed have been carefully selected to meet the needs of the smaller as well as the larger public library, and those of academic and special libraries. How far the greater frequency of publication enables the "Index" to keep pace more closely with the influx of material cannot fairly be judged from a single issue, and the full advantage will probably be derived in the annual cumulation.

THE BULGARIAN ACADEMY OF SCIENCES

By Dr. D. R. NEWTH

Department of Zoology, University College, London

ALTHOUGH it can be said to have its origins in the foundation, in 1869 at Braila in Rumania, of the Bulgarian Literary Society, the Bulgarian Academy of Sciences did not become a model of the traditional European academy until much later. The Literary Society moved to Sofia in 1878 after Bulgaria's liberation from Turkish rule; but it was not until 1911 that the intentions of its founders were realized and it became, in fact and in name, an Academy of Sciences. From then until 1944 it remained a body of scholars, with the publication of learned periodicals and the holding of scientific meetings as its main functions.

Plans for the extension of the work and responsibilities of the Academy were discussed between 1944 and 1947, and its present form was determined by a law passed in 1947 and a decree issued in 1949. These have turned the Academy into a body controlling the activities of a number of research institutes and exercising quasi-ministerial authority over a great deal of Bulgarian science. At present its work is carried on by seven sections, each with several institutes. These are: (1) Physics, Mathematics and Technology (with three institutes); (2) Geology, Geography and Chemistry (with three institutes); (3) Biology and Medicine (with twelve institutes); (4) History, Archæology and Philosophy (with seven institutes); (5) Law and Economics (with two institutes); (6) Linguistics, Ethnography and Literature (with three institutes); (7) *Beaux arts* (with three institutes). In the near future the section of Biology and Medicine is to be divided into two, a new section of Agrobiology with five institutes and a section of Medical Science with seven.

Not all these institutes are primarily research organizations. Thus the Zoological Gardens in Sofia and the Ethnographic Museum have the status of Academy institutes. In establishing new institutes it has been the policy of the Academy to proceed with some caution. Where the case for a new institute is held to have been made, it is started with a small nucleus of workers, perhaps as few as three, and probably not in quarters of its own. It is then allowed to grow, and if its work flourishes it will be given buildings designed for it, some years after its inception. Most of the fully fledged institutes have between fifteen and twenty scientific workers headed by a director (normally, but not always, an academician) and controlled by a council upon which are represented the sectional committee of the Academy, appropriate Ministries and the heads of the institute's research teams. Such institutes may publish an annual bulletin of researches; thus the Biological Institute (until his recent death directed by Prof. M. Popov) has just issued its fifth, while the younger Institute of Morphology, under Prof. Hadjiolov, has just published its first.

The bulletins and the other publications of the Academy are well produced and the use of French and German, and to a lesser extent English, is common.

The Academy is also represented at the conferences which plan the work of institutes other than its own, and through its Presidium, Council of Co-ordination and planning commissions is coming more and more to co-ordinate the scientific life of the whole country. University departments do not come under the Academy or receive grants from it; but university teachers may use the facilities of Academy institutes for researches that can best be carried on in them.

At the present time there are forty-eight academicians, forty-six corresponding members and approximately five hundred full-time qualified workers in the Academy's institutes.

The Academy is conscious of the fact that during its re-organization it has not paid as much attention as is desirable to developing working relations with scientists abroad, and particularly with those of the West. It hopes next year to take a first step in improving its international contacts by inviting numbers of foreign scientists to visit it.

INSTITUTE OF CHEMISTRY OF IRELAND

SUMMER SCHOOL IN ORGANIC CHEMISTRY

THE Institute of Chemistry of Ireland held its first summer school during July 6–9 in University College, Dublin, the school being a refresher course on organic chemistry, with ninety-four participants. In his opening address, the president of the Institute, Prof. T. P. Dillon, of University College, Galway, stressed the necessity for chemists during their careers to return to the university at intervals to obtain some knowledge of advances made in fields of chemistry outside their special interest.

A series of four lectures on stereochemistry was given by Prof. T. S. Wheeler, professor of chemistry, University College, Dublin. He showed how hybridization of *s* and *p* orbitals gives the shapes of the methane, ethylene and acetylene molecules. He described how sp^2 hybridization is involved in the Walden inversion and explained how the original Mills–Nixon theory was no longer applicable. In treating of the stereochemistry of tetrahedral carbon, he discussed the necessary and sufficient conditions for molecular dissymmetry. Fisher's system of projection and his ideas as regards relative configurations were explained. Rosanoff's glyceraldehyde standard and the manner in which it is related to the serine standard by the Ingold school were described. After a discussion of absolute configuration, the stereochemistry of *cyclo*hexane and the decalins was demonstrated by means of models, and the application of conformational analysis to steroids was shown. In his closing address, Prof. Wheeler outlined recent work on the absolute configuration of natural products such as the steroids. The fluorescent glass models of *cyclo*hexane, decalin and steroid systems made by Mr. W. Brady, of University College, Dublin, were greatly appreciated.

In two lectures Prof. Wesley Cocker, University professor of chemistry, Trinity College, Dublin, dealt with new reagents and techniques. He criticized the old idea that the aldehyde–Girard products are more stable than the ketonic adducts and went on to describe newer methods for isolating carbonyl compounds. He then described modern specific catalysts for reducing alkene and carbonyl compounds. Recent oxidizing agents which are specific for various groups were outlined, and in conclusion the work of Linstead and others who have produced long-chain fatty acids by a variation of the Kobe electrolytic synthesis of paraffins was described.

In the two hours allotted to him, Mr. P. W. D. Mitchell, Lasdon Fellow of the Medical Research Council of Ireland, described briefly the symbols and terminology used in absorption spectroscopy. He indicated how the positions of the regions of absorption and the intensity might be correlated empirically with the nature and distribution of chromophores and auxochromes in the molecule and then described some work in which he is engaged for the Medical Research Council of Ireland. In this work the ultra-violet absorption spectra are used as a means of determining molecular weights and also as a method for the identification of sugar osazones.

Dr. E. F. McCarthy, senior Fellow of the Medical Research Council of Ireland, outlined recent advances in electrophoretic technique and its application to the separation of high- and low-molecular-weight substances of biological importance. He discussed the relative merits of boundary and zone electrophoresis with reference to his own work on the identification of blood proteins. Dr. McCarthy also described the more recent refinements in the estimation of molecular weights by osmotic pressure measurements.

Two lectures on "Distillation" were delivered by Mr. F. T. Riley, lecturer in chemistry in University College, Dublin, dealing with liquid–vapour equilibria and with the theoretical basis of modern laboratory fractional distillation. Laboratory fractionation practice in the 1920's was contrasted with present-day methods. Mr. Riley emphasized the changes brought about by the introduction of controlled reflux, and packed columns. He then reviewed the factors influencing separation efficiency and described the high-efficiency column working in the Department of Chemistry of University College, Dublin. This column has a packed length of 9 ft., and its performance is equivalent to that of a column containing at least two hundred theoretical plates. A feature of this column is the intermittent vapour draw-off device which is useful with an azeotropic mixture that separates on condensation.

Prof. F. J. Coll, professor of chemistry in University College, Galway, gave two lectures on "Chromatography" and discussed this technique under the following headings: absorption chromatography, partition chromatography, paper chromatography, ion-exchange chromatography and electrochromatography. Many excellent paper chromatograms of sugars, prepared by Prof. Coll, were used for illustrating the points described. Other experimental demonstrations were much admired.

Two lectures on organic chemistry and analysis were given by Dr. Cecil L. Wilson, reader in analytical chemistry in The Queen's University, Belfast. Beginning with a review of the development of analytical chemistry, he went on to discuss the use of micro-methods in the laboratory. He described the application of organic reagents in gravimetric, titrimetric and colorimetric procedures and showed how the requirements for a 'classical' organic reagent have been modified by the addition to this class of the 'complexones', which cannot be regarded as following the accepted pattern. The inorganic analyst, in particular, is bound, in the future, to take more note of the methods of his organic colleague, since he will more and more be faced with problems of compound analysis rather than of ion analysis.

Mr. C. D. O'Briain, Department of Chemistry, University College, Dublin, organized an excellent display of scientific apparatus, the material being supplied by a number of manufacturers and agents.

EVA M. PHILBIN

PHYSICS IN ISRAEL

THE seventy-fifth birthday of Prof. Albert Einstein was celebrated in Israel by a scientific convocation which was held on March 14 in Jerusalem, under the joint auspices of the Hebrew University of Jerusalem; the Technion, Haifa; the Weizmann Institute of Science, Rehovot; and the Research Council of Israel. Tributes were paid to Prof. Einstein by Mr. Y. Ben-Zvi, the Israeli president, Mr. M. Sharett, the Israeli prime minister, and Prof. B. Mazur, president of the Hebrew University, and various aspects of Prof. Einstein's contributions to science were discussed by Prof. G. Racah of the Hebrew University (quantum theory), Prof. C. Pekeris of the Weizmann Institute (Brownian movement), Prof. N. Rosen of the Technion (relativity) and Prof. S. Sambursky, director of the Research Council (cosmology).

In addition, the March number of the *Bulletin of the Research Council of Israel* (3, No. 4; 1954) is dedicated "with the highest esteem and affection of the scientists of Israel" to Einstein in honour of his birthday, and contains a photograph of Prof. Einstein as frontispiece. The contents consist of twenty-four original contributions, mainly devoted to mathematics or theoretical physics, the abstracts of the papers presented at the inaugural meeting of the Israel Physical Society held during April 12–13, 1954, and six short research notes. The *Bulletin*, which is in English, contains, in addition, abstracts of the original contributions in both Hebrew and English.

The inaugural meeting of the Physical Society consisted of a general session, opened by the Society's first president, Prof. G. Racah, at which two addresses were delivered, one by E. D. Bergmann on the influence of modern physics on organic chemistry and the other by M. Chwalow on the role of physics in industry, and four other sessions devoted to general and industrial physics; theoretical physics; atomic, nuclear and molecular physics; and methods and instruments. The abstracts indicate that work in the experimental field of physics is gradually being built up alongside the numerous theoretical studies, and show that recent activities include the construction of a thin lens magnetic β-ray spectrometer, and of a Couette viscometer for precision measurement in the centipoise ranges, the measurement of the absorption and scattering of 1–3 cm. radiation by a d.c. discharge in helium and air using a low-powered klystron as microwave generator, and experiments on luminescence.

S. WEINTROUB

ONTARIO RESEARCH FOUNDATION

REPORT FOR 1953

IN the annual report for 1953 of the Ontario Research Foundation*, by the director of research, Dr. H. B. Speakman, to which is appended a list of papers published during 1953 and the financial statement, attention is directed to the increase of almost 100 per cent in the research work performed for industry and under contract for government agencies during the five years 1949–53. Income from such sources increased from 277,777 dollars to 506,189 dollars, and the Provincial grant was increased from 167,904 to 260,230 dollars, the Federal grant remaining at 25,000 dollars. Dr. Speakman urges that these grants should increase in accordance with the demands made on the Foundation. While there was no increase in administrative staff during the period under review, the scientific staff increased from fifty-one to sixty-seven and technical staff from thirty-eight to forty-six. In biochemistry, the laboratory dealing with canning problems was closed ; but the fellowship on the utilization of the hulls of rice has led to the commercial production of humidifier plates from rice hull ash and to a high-temperature, light-weight insulating refractory now under study by a large manufacturer of fire-bricks in the United States. The possibility of utilizing whey with inorganic and cheap ammonium salts for the production of a yeast high in complex proteins of nutritive value in the diets of domestic animals is being explored, and considerable progress has been made in the production of tanning materials from waste sulphite liquors and the waste phenolic liquors from petroleum refineries, as well as in the development, in the oils and fats laboratory, of formulæ and methods for a butter-like spread, with good keeping properties, which can be used by the Armed Services under a wide range of climatic conditions.

In chemistry the Air Pollution Laboratory is making a systematic study of atmospheric conditions in the Sarnia area, in which several refineries and chemical plants are operating, under varying climatic conditions, and similar surveys are in progress in Maitland and Millhaven. The Electroplating Laboratory made important progress in studies of the influence of the physical metallurgy and mechanical processing of the basic metal on the subsequent electroplating process. Encouraging results have been obtained with a tanning agent prepared by the Organic Section from lignin, and similar compounds are being tested as dispersing agents, while a similar product has shown promise as a relatively cheap thermo-setting resin with water-repellent properties for use in the manufacture of boards from sawdust and other wood waste.

The Department of Engineering and Metallurgy, which is still in urgent need of more space and facilities, has continued its fundamental work in physical metallurgy, and investigations in ferrous metallurgy have been extended to include the pretreatment and concentration of ores to provide concentrates for the basic process. The hypothesis that changes in the lay-length of a wire rope in service may provide reliable indications of weakness and ultimate failure has received considerable support from results obtained on experimental machines. The Department of Research Services continued to increase its contacts with industry and also the number of repeat requests for service.

In the Department of Parasitology more attention was given to basic research. Work on the tapeworms occurring in carnivorous animals, especially foxes, continued, that on a hydatid disease in moose and wolves was concluded, and the life-history of the bot fly which lives parasitically in chipmunks has been determined. The survey of the Algonquin plain by the Department of Physiography was carried forward from Espanola to Saulte Ste. Marie, but the mineralogical study of soils in southern Ontario was temporarily halted. An ecological study of the growth of soybeans in southern Ontario and the adjoining States of the United States has been started.

In the Textiles Laboratory the emphasis had passed to problems connected with product development, including fabrics for wearing apparel, household furnishings and industry. Pressing temperature studies of the maximum temperature to which fabrics may be submitted have included a comparative study of viscose and acetate rayon, cotton, linen, nylon and orlon. Under the Nylon Fellowship of Canadian Industries, Ltd., a study of available methods and instruments for measuring resistance to abrasion supports the view that abrasion resistance and wear cannot be correlated with confidence. The influence of chemicals and temperature on the tensile strength and bursting strength of filter cloths was being investigated, and apparatus and experimental techniques were being developed to investigate the influence of cloth construction on the efficiency of a filter press.

BRITISH ELECTRICAL AND ALLIED INDUSTRIES RESEARCH ASSOCIATION

ANNUAL REPORT FOR 1953

THE report for 1953 of the British Electrical and Allied Industries Research Association*, the thirty-third year of its operation, records, in addition to summarizing the results of the year's work, the inception of an important new development. This is the commencement of the erection at Leatherhead of buildings which will ultimately completely re-house the Association's laboratories, at present situated at Perivale. The cost of this project, amounting to some £400,000, will be met for the most part by special capital contributions from the members, together with a grant from the Department of Scientific and Industrial Research which will probably amount to £100,000.

The main fields of activity of the Association necessarily form a fairly stable pattern over a period of years. Work on high-power switch gear and on dielectric materials have long occupied prominent places in the research programme, and continue to do so. Both these branches illustrate a feature which is characteristic of much of the work of the Association, namely, that the investigation of problems of direct technological importance often stimulates investigations of a fundamental character and produces new knowledge in the field of pure science. Experimental and theoretical researches are being pursued into the fundamentals of arcing phenomena and into the breakdown processes of discharges in gases and in solid dielectrics where the breakdown is occasioned by internal discharges. Work on the general theory of electrons in solids has produced a canonical transformation which can be applied to the movement of slow electrons in ionic crystals and which permits an estimate to be made of the energy and mass of 'polarons', that is, electrons carrying some ionic displacements with them.

---

* Ontario Research Foundation. Annual Report, 1953. Pp. 82. (Toronto: Ontario Research Association, 1954.)

* British Electrical and Allied Industries Research Association. Thirty-third Annual Report—1st January, 1953, to 31st December, 1953. Pp. 160. (Leatherhead: The Association, 1954.)

The work on surge phenomena has been concerned mainly with surges on systems and in transformers. Surges on transmission lines arising from lightning have been recorded on equipment installed for that purpose, and analyses have been made of large numbers of fault reports from the British Electricity Authority and area boards. It is noted, however, that the incidence of thunderstorms during the year under review was abnormally low, and in the London area two hundred magnetic link lightning detectors did not record a single disturbance. In the field of transmission and distribution the Association has continued its work on the continuous and short-circuit rating of power cables and has begun to extend these investigations to higher frequencies, in the first instance to 400 c./s.

In connexion with the research on generation by wind power which has been in progress for some time, the Association has carried out a wind-power survey of the British Isles and it is stated that this is now practically complete. A gust recorder installed at Costa Hill in Orkney, where there is a 100-kW. wind-power generator in operation, recorded during the gales at the end of January 1953 gust velocities of 125 m.p.h.

Under the Power Plant Section, work continues on the creep and corrosion resistance of steels at high temperatures, on condenser tubes, and on the properties of high pressure – high temperature steam. It is noted that a detailed study of the creep and tensile properties of a large molybdenum – vanadium steel turbine-rotor forging is in progress and is well advanced.

Associated with the researches on switch and control gear are programmes of work conducted in the laboratories of the Safety in Mines Research Establishments at Buxton and at Sheffield. One of the problems under investigation is that of 'pressure piling' in flameproof motors. This is a phenomenon in which the pressure generated on explosion is greater with the machine running than with the machine stationary. Determinations are also being made of safe flange gaps for inflammable mixtures. An important allied investigation is in progress on intrinsically safe apparatus.

Among the items reported under "Unclassified Researches" is a significant improvement in the life of the hydrogen–oxygen fuel cell resulting from the development of a method of diminishing the corrosion of the oxygen electrode. In the same section it is stated that further work has been done on the 'self adjusting welding arc' and that the extension of the practical application of the surge injection principle for arc maintenance is being pursued.

It is evident from many references in the detailed sections of the report that the work which is supported by the Association in university departments throughout Britain is being actively maintained. The report concludes with a list of some forty papers and articles published by the staff during the year and about half that number of publications based on technical reports of the Association. There is a further list of translations from foreign journals and of bibliographies which have been prepared.

The report taken as a whole gives the impression that the Association is not only carrying on a large volume of research which is of direct importance to the electrical industry and to the community, but also that its policy is one of vigilant surveillance of the whole field to ensure the effective co-ordination of its work with the general body of research activity throughout the industry and in government establishments. The presentation of the individual sections of the Association's work in the report is made in a very satisfactory way; but there is little to indicate the relative scale of effort associated with each. It would add appreciably to the interest and value of the report if some indication could be given as to the relative magnitudes of the Association's various fields of activity.

PYROPHOSPHATASES IN PLANTS DURING GROWTH

By DR. B. NAGANNA* and C. E. SRIPATHI

Dept. of Chemistry, Madras Veterinary College, Madras 7

THE occurrence of an alkaline pyrophosphatase, active only in the presence of added magnesium ions (0·02 *M*), was recently reported[1] in fresh potato extracts. Further studies have revealed its occurrence in many other plants. Unlike animal tissues[2], plant tissues show high acid pyrophosphatase activity also. With the same substrate concentration, the alkaline pyrophosphatase activity is found to be always greater than that of the acid pyrophosphatase in green leaves, whereas in seeds the reverse is observed. This unequal distribution of the two enzymes that act on the same substrate led us to consider whether any significant differences in their elaboration during plant growth could be observed which would throw some light on their specific metabolic functions.

Wheat (*Triticum vulgare*), a monocotyledon, showing more acid pyrophosphatase and less alkaline pyrophosphatase activities, and french beans (*Phaseolus vulgaris* L.), a dicotyledon, showing no alkaline pyrophosphatase but very high acid pyrophosphatase activities, were germinated on loose soil and analysed at intervals. When roots and shoots had developed, separate analyses were conducted with each part. The enzyme extracts obtained by maceration of weighed fresh tissues with ice-cold double-distilled water were centrifuged and kept in an ice-box. They were further suitably diluted (1 in 10 to 1 in 1,000) just before the assay of the enzymes. Both the acid and the alkaline pyrophosphatases and also the acid phosphatase were assayed as follows.

The incubation mixture (5 ml.) contained 0·5 ml. of the enzyme extract in each case, and 4 ml. of veronal–acetate buffer (Michaelis[3]), *p*H 5·32, and 0·5 ml. of neutralized sodium pyrophosphate (0·01 *M*) for acid pyrophosphatase, 3·9 ml. of buffer, *p*H 8·68,

---

* Present address Dept. of Biochemistry, Andhra Medical College, Visakhapatnam India.

Table 1. ACID AND ALKALINE PYROPHOSPHATASES AND ACID GLYCEROPHOSPHATASE ACTIVITIES OF DIFFERENT PARTS OF WHEAT PLANT

Days after germination	Nature of the plant tissue	Enzyme activity in γP per min. per gm. fresh tissue		
		Acid PP-ase	Alk. PP-ase	Acid GP-ase
0	Wheat grains	390	150	96
1	"	360	96	55
2	Wheat seedling (roots 2–4 cm.; shoots 0·5–0·8 cm.)	420	175	145

* Values calculated from the weights and activities of the different parts of the seedlings.

0·1 ml. of magnesium chloride (1·0 *M*), and 0·5 ml. of unneutralized sodium pyrophosphate (0·01 *M*) for alkaline pyrophosphatase, and 4 ml. of buffer, *p*H 5·32, and 0·5 ml. of sodium-β-glycerophosphate (0·1 *M*) for acid phosphatase. The incubations were carried out at 40° C. for 10 min. in the case of the pyrophosphatases and for 20 min. in the case of phosphatase. The enzyme action was stopped by trichloracetic acid, and the liberated orthophosphate estimated by the method of Fiske and Subbarow[4]. The results are shown in Tables 1 and 2.

As these experiments were designed primarily for studying the comparative distribution of the three enzymes at different stages of plant growth, the activities are expressed as micrograms phosphorus liberated per min. by the enzyme present in 1 gm. of fresh tissue. The results with wheat show that all three enzymes are increased during germination, the increase in each being confined largely to a particular tissue. The french beans showed no alkaline pyrophosphatase activity even though the acid pyrophosphatase activity was unusually great. This high activity of the latter, exclusively confined to the cotyledons, gradually decreased with plant growth. Eight days after germination, when the primary leaves were fully developed, the acid pyrophosphatase of the cotyledons, which were very much shrunken, was reduced to about 10 per cent of the original value. These results suggest the participation of this enzyme in the catabolic processes in the cotyledons by which the reserve food materials are converted into simple metabolites suitable for utilization by the growing embryo. Further, the acid pyrophosphatase content of the green leaves is relatively high, indicating that it has a role in metabolic processes involved in the translocation of the food material in the plant. These facts explain the occurrence of large amounts of acid pyrophosphatase in vegetable tissues, whereas animal tissues contain only negligible amounts, even though both tissues contain appreciable amounts of the alkaline pyrophosphatase[3].

Table 2. ACID AND ALKALINE PYROPHOSPHATASES AND ACID GLYCEROPHOSPHATASE ACTIVITIES OF DIFFERENT PARTS OF FRENCH BEAN PLANT

Days after germination	Nature of the plant tissue	Enzyme activity in γP per min. per gm. fresh tissue		
		Acid PP-ase	Alk. PP-ase	Acid GP-ase

	Pulp	168	96	62
—	Mature pods (skin dried up)	16,000	nil*	160

* Activity at *p*H 8·68 was less with magnesium chloride than without.

† Values calculated from the weights and the activities of the different parts of the seedlings.

Although the tender pods of the french bean had both the acid and alkaline pyrophosphatases in nearly equal amounts, the alkaline pyrophosphatase disappeared as the pods matured, and at the same time the acid pyrophosphatase was tremendously increased. The former, absent in the seed, developed in the plumule even in one day after germination. It rapidly increased as the primary leaves developed. The activity of the primary leaves decreased as the secondary leaves developed, which showed high activity. The high activities of the secondary leaves also decreased when other leaves appeared. The significant elaboration of the alkaline pyrophosphatase in the growing leaves, which are the sites of intense metabolic activity, indicates the important role of this enzyme in photosynthesis. Any actively respiring tissue requires the presence of adequate amounts of coenzymes to participate in the oxido-reduction processes. Reversible enzymatic mechanisms by which two very important respiratory coenzymes, diphosphopyridine nucleotide and flavin-adenine dinucleotide, could be synthesized have recently been reported[5,6]. Equivalent amounts of pyrophosphate ions are said to be formed with diphosphopyridine nucleotide (or flavinadenine dinucleotide) reversibly from adenosine triphosphate and nicotinamide mononucleotide (or riboflavin phosphate). Removal of pyrophosphate ions enzymatically would lead to a shift in the equilibrium towards formation of more nucleotide. The actual enzyme responsible for the removal of pyrophosphate ions must be the alkaline pyrophosphatase, since it acts at an alkaline *p*H, and it has an immeasurably high affinity for the substrate[2]. Its rapid elaboration in the leaves from plumules one day old onwards supports such an assumption.

It may therefore be concluded that the alkaline pyrophosphatase is associated with the anabolic processes in the leaf, while the acid pyrophosphatase participates in the catabolic processes taking place during translocation of the carbohydrates synthesized in the leaf.

ATOMIC WEIGHTS OF THE MONOISOTOPIC ELEMENTS

By Prof. HENRY E. DUCKWORTH

Department of Physics, Hamilton College,
McMaster University, Hamilton, Ontario

THE work of Aston in the measurement of isotopic abundances and masses made it possible to compute, for the first time, the chemical atomic weight from purely physical data. As a result of the development of modern mass spectrometers and mass spectrographs, the accuracy of these physically determined values has steadily improved to the point where they are now generally recognized as being more reliable than their chemically determined counterparts. This communication is concerned with the physical atomic weights of the twenty-two monoisotopic elements, and supplements a review published[1] two years ago by Scott and Bettman.

Accurate physical masses are known for seventeen of the monoisotopic elements. In the remaining five cases, namely, cæsium-133, terbium-159, thulium-169, tantalum-181 and gold-197, reliable estimates of the mass can be made in the following manner. If the points representing the stable odd-A nuclides on a graph of 'mass defects' (mass defect is difference between atomic mass of a nuclide and its mass number) be joined together, they are found to lie on a comparatively smooth curve, which shows abrupt changes in slope only at the positions of the major nuclear shells. This regularity has been demonstrated[2] for the region $80 < A < 130$ in a recent paper by Collins, Johnson and Nier. In order better to establish the position of this odd-A line in regions where few odd-A masses have been measured, as in the rare-earth region, a second curve may be drawn which is tangent to the series of curves joining the even-A isotopes of the even-Z elements. This second curve is based upon a much larger body of experimental data, and is shown in Fig. 1 as a solid line. The open circles lying above this line represent the stable odd-A nuclides in this region the masses of which are known, and they can be seen to be displaced from the solid curve by a regular amount. One can, therefore, obtain the masses of the unknown odd-A nuclides by interpolation: in no case would the error associated with such an estimate exceed 3 milli-mass-units, an amount shown in the lower right-hand corner of Fig. 1. The five interpolated values are shown on the graph as closed circles.

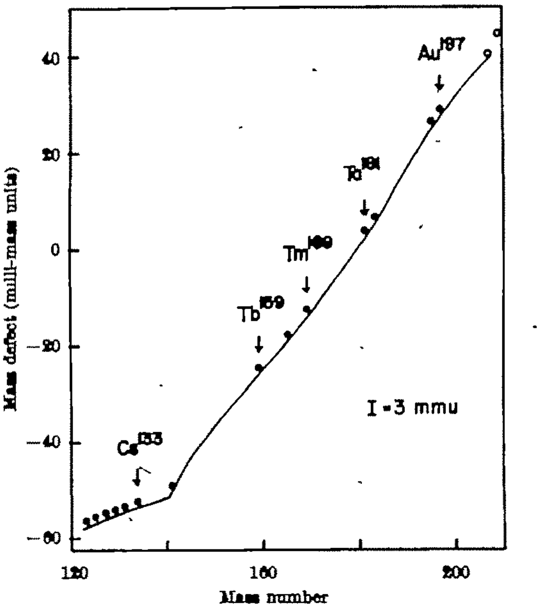

Fig. 1. Plot of mass defect versus mass number. The solid line is tangent to the curves formed by the even–even isotopes of the even-Z elements. The open circles represent odd-A nuclides the masses of which are known, while the closed circles are interpolated values for the five monoisotopic elements the masses of which have not been measured

The masses of the twenty-two monoisotopic elements, with appropriate footnotes indicating their source, are shown in the accompanying table, and their values on the chemical scale are compared with the official chemical atomic weights. The value of the conversion factor from the chemical to the physical scale has been taken to be 1·0002783 ± 5, as recently determined[3] by Nier for atmospheric oxygen. There is seen to be exact agreement in the case of eleven elements; in three cases the approved value is too small; while for the remaining eight elements it is too large, sometimes by a substantial amount.

Some of these discrepancies have been recognized by the Committee on Atomic Weights. In its 1951 Report, the Committee remarked[4] that revisions appeared necessary in the cases of sodium, manganese, terbium, thulium and gold, and even suggested the direction and probable magnitude of the changes likely to be made at the time of the next formal report. These suggested revisions would remove the discrepancies for sodium, manganese, terbium and gold; but the proposed value of 169·0 for thulium would be slightly too high. It is desirable that the revisions indicated by the table should also be made for the elements arsenic, yttrium, praseodymium, tantalum, bismuth and thorium.

One is tempted to assess the adequacy of the chemical techniques for a given element by comparing its chemically determined atomic weight with that computed from physical data. For this purpose the table presents a somewhat over-optimistic picture, in that the official atomic weights of aluminium, phosphorus, scandium and iodine have already been revised by the Committee to coincide with the physical values. There is, therefore, exact agreement between the chemically and physically determined values for substantially less than half the elements in this group. It is not proper to generalize on the basis of this comparison since the monoisotopic elements are not, in a chemical sense, representative. With the exception of beryllium and thulium, they are all elements of odd atomic number and, hence, represent only some of the chemical families.

WHY USE INBRED LINES?

By DR. J. D. BIGGERS and P. J. CLARINGBOLD

Department of Veterinary Physiology,
University of Sydney

THE use of inbred lines of both plants and animals has often been recommended in biological investigation. Recently, in order to find the basis of the recommendation, we have examined the literature. The purpose of this communication is to bring to general notice the present state of knowledge on the use of inbred lines. In communications which have appeared since the present article was first submitted for publication, Gruneberg[1] and McLaren and Michie[2] have dealt with the same problem. The genetic aspects of this problem have been discussed by Grüneberg and will not be considered further.

In the second decade of this century, inbred lines of guinea pigs and rats were developed; in the case of the rat, the descendants became the well-known Wistar strain. The inbred rats were characterized by a uniform body-weight and appearance, in contrast to randomly bred animals[3].

Soon after this period, the standardization of hormones and vitamins was developed. A unit of these substances was often arbitrarily defined in terms of a standard animal; for example, a unit of the parathyroid hormone was defined "as 1/500th of the amount required to produce in a dog of 20 kg. weight an increase of 5 mg./100 c.c. in serum calcium in 15 hours"[4]; the rat unit of oestrogen was defined as "the quantity of material necessary to induce oestrus as judged by the smear method in an ovariectomized, sexually mature rat weighing 140 ± 20 gm."[5]. These early definitions indicate that great value was placed on strains possessing uniform bodily characteristics, and it was for this reason that the Wistar rats were rapidly distributed[6].

Investigators soon recognized that the definition of the original 'animal units' of hormones and vitamins completely overlooks the effect of variation between animals. The establishment of international standards, in the mid-thirties, overcame this objection and at the same time led to the adoption of biometric techniques[7]. In these methods an estimate is made of the experimental error, and this is used for giving fiducial limits to relative potency estimates. In the wider field of biological experimentation, the estimate of experimental error is used to judge the significance of treatment effects[8]. Cochran and Cox[9] list three main ways of decreasing experimental error: (1) by increasing the size of the experiment, (2) by refining the experimental technique, (3) by handling the experimental material so that the effects of variability are reduced. We may include in the third of these methods the selection of homogeneous biological material. In many assays[10], for example, growth assays[11], the variability within litters is considerably less than the variability between litters. Since litters are genetically more uniform than the population as a whole and their use gives greater accuracy in bioassay, it was concluded that the use of genetically homogeneous inbred animals would also increase accuracy.

Thus over a period of about thirty-five years a traditional desire for inbred lines has developed, and these have been recommended in many modern text-books and many papers. We have not found one published investigation of the response to a treatment in which the advantage of inbred lines over randomly bred animals has been experimentally substantiated. In his recent book on the statistics of bioassay, Finney[10] gives two references on the subject.

The first reference is, through Gaddum[12], to the work of Winton[13] on the assay of red squills. In the original paper, Winton concluded that one inbred Wistar rat was equivalent to ten rats of mixed origin (black, black-and-white, and wild). No efficient statistical method was then available for the analysis of these results. In 1933 Gaddum[12] re-examined Winton's data using the newly devised normal equivalent deviate transformation, and he concluded that one Wistar rat was equivalent to six mixed rats. The statistical analysis applied by Gaddum is also inefficient, since iteration was not carried out to the maximum likelihood estimates and empirical weights were used. This procedure may seriously bias the estimates when the number of animals in an experiment is small and many 0 and 100 per cent responses occur, as in Winton's data. Consequently, we have re-examined his figures using the standard modern probit technique[14].

Winton's data have been grouped into intervals (range 0·2 gm./kgm.) for the purpose of analysis. Death (*D*) has been scored as a positive response, and survival (which includes unaffected (*N*) and convulsed (*C*)) has been scored as a negative response. A log dose/probit response regression line has been fitted by the method of maximum likelihood to each set of data, iteration being continued until successive values of the regression coefficient (slope) differ by less than one-tenth of the standard error[14]. An analysis of the slope differences has been made by a partitioning of χ^2 (Table 1). Since slope is the

Table 1. PARTITIONING OF χ^2 FOR THE DATA OF WINTON (ref. 13)

Source of variation	D.f.	χ^2	P
Between strains	(2)		
Inbred ♀ v. Inbred ♂	1	0·01	$0·95 > P > 0·90$
Inbreds v. Mixed	1	1·24	$0·3 > P > 0·2$
Heterogeneity	26	23·51	$0·7 > P > 0·5$

reciprocal of the square root of the variance of the individual effective doses of the population, this analysis is an examination of variability. Although the estimates of slope suggest a difference between the inbred and mixed animals, the analysis indicates that the differences are those of random sampling. This efficient analysis provides no evidence of a significant difference between the mixed and inbred animals and therefore the conclusions of Winton and Gaddum are incorrect. Furthermore, it must be emphasized that the mixed stock of rats used by Winton is a heterogeneous collection and not a randomly bred strain, and had a significant difference been found its interpretation would still be difficult.

The second reference given by Finney is to the work of Morrell and Allmark[16] on the toxicology of neoarsphenamine in rats. While it is doubtful if the animals used in this investigation fulfil the definition of inbred, they were not found to be significantly better than randomly bred animals.

Emmens[17] studied the action of œstrone in Strong's *CBA* strain of mice and found, to his surprise, that they were significantly more variable in response than the randomly bred colonies normally used. Recently this finding has been confirmed in *CBA* and *C57* mice, using œstrone and œstradiol-3 : 17β [18]. In both these investigations the mice were inbred to at least thirty generations and may thus be considered homozygous. Since inbred lines are so often recommended, it is very surprising that little work can be found on the comparison of the variability of inbred and randomly bred animals. The experimental work reviewed above offers no evidence that inbred lines may be advantageous and even suggests they may be disadvantageous.

A considerable and well-established disadvantage of inbred lines is the decline in vigour often associated with inbreeding[19]. This is manifested in a decline in fertility, fecundity and health. When a large colony is required, many breeding animals need to be maintained in order to produce the colony in a reasonable time.

It has been known for many years that F_1 hybrids between inbred lines are characterized by high vigour. This phenomenon is known as heterosis or hybrid vigour, and has been discussed extensively in recent times[20,21]. In addition, the hybridization of inbred lines leads to two other phenomena: (1) the mean response of the F_1 generation often lies outside the interval between the mean responses of the parental stocks; (2) the F_1 generation is less variable than the parent inbred populations. The first phenomenon has often been described and studied because of its economic importance. The second phenomenon, however, has been studied very little and only an occasional reference may be found.

McLaren and Michie[2] have recently demonstrated that the variability of inbreds is 3·5 times greater than that of F_1 hybrids, using the duration of narcosis to sodium pentabarbital as the test criterion. Claringbold and Biggers[18] have studied the vaginal response to œstrogens of reciprocal F_1 hybrids of *C57* and *CBA* mice and found the hybrids to have 25 per cent of the variability of the inbreds, and they were always less variable than the randomly bred albino stock. Thus in studies of œstrogens the use of these F_1 hybrids has tremendous advantages because of the large reduction in biological variation.

Strong[22] states that the use of F_1 crosses deserves consideration. However, his reasons are based on the fact that F_1 hybrids are superior to inbreds in health and longevity, and that "animals of any particular hybrid type show as great uniformity as the inbreds do". This latter statement is true so far as genetic variability is concerned, but ignores the possibility of interaction between genotype and environment. Fisher[23], too, suggests the out-crossing of two inbred lines to produce a large number of genetically uniform mice in a short time. The low vigour of inbred animals results in a low weaning-rate, but following hybridization the weaning-rate is high. In the case of mice the litter size of hybrids may be two to three times greater than the litter size of inbreds. Thus the F_1 hybrids are much the easier to breed in large numbers, and only a small stock of inbred animals need be maintained for their production.

In view of the above considerations, the automatic use of inbred lines may well be an inefficient procedure in biological experimentation. Investigators should examine their material to see whether inbreds, F_1 hybrids or randomly bred animals are the most suitable for their work. It is probable that the best use of inbred lines is to produce F_1 hybrids. The manifestation of heterosis, however, will depend on the material studied and no general rule can be laid down. In the concluding paragraphs of his book, "The Theory of Inbreeding", Fisher[23] discusses the necessity of having many inbred lines so that suitable crosses can be made for special environments and purposes. Although this was written with particular reference to livestock and plant improvement, it is possible that these ideas could be exploited in experimental procedures.

Psalliotin, the Antibiotic of *Psalliota xanthoderma*

THE antibiotic activity of the edible mushroom *Psalliota xanthoderma* was first described in some detail by Atkinson[1] in Australia. Wilkins[2] in England also recorded this mushroom as being antibiotic. Atkinson gave a number of characteristics of the antibiotic substance and also a list of sensitive and insensitive bacterial species, but refrained from naming the substance as a new antibiotic. Its peculiar and haphazard lability defeated attempts to concentrate and purify it, and the work was temporarily abandoned as the mushroom supply ran out.

This year a good crop of *Psalliota xanthoderma* appeared in and around Adelaide and work on purification of the antibiotic was recommenced using paper chromatography of aqueous extracts of mushroom stipes. Erratic results were obtained, some papers showing a good antibiotic zone near the solvent front, others showing no zone. The amount of activity on the paper was shown to depend upon the extent of exposure to daylight during the preparation of the spot of mushroom extract (100 μl.) and during the running and subsequent handling of the chromatogram. Spots prepared in dim light, run in the dark and afterwards handled in dim light, invariably produced antibiotic zones near the solvent front.

The sensitivity of the antibiotic in crude extracts to different types of light was investigated by exposing dried spots of extract (100 μl.) for various times to the diffuse daylight (not direct sunlight) of the working bench under the window. At the same time, and in the same position, similar spots were exposed under various Wratten filters, and a control spot was kept in a light-proof box.

This box control spot tested after four hours and twenty-four hours on the bench at room temperature showed excellent activity comparable to that of a similar spot kept in the dark in the refrigerator. Thus no deterioration occurred in twenty-four hours at room temperature in the dark. Rapid deterioration occurred, however, in diffuse daylight, as little or no activity was detected in the spots exposed directly to daylight for one to four hours. Good activity similar to the box control was found in spots exposed up to four hours under Wratten filters *A*, *B*, *C*, *E*, *F*, *G*, *H* and *Kl*, which were thus protective. The *D* filter (dark violet) was not protective, however. Spots exposed under it for one to four hours showed reduced or barely detectable activity.

Exposure to short-wave ultra-violet also inactivated the antibiotic extract. With the lamp used at present, emitting mainly in the 250 mμ region, complete inactivation of dried spots occurred at 18 cm. distance in one hour, and considerable reduction of activity in twenty minutes. Long-wave ultra-violet was probably responsible to a large extent for the inactivation produced by daylight, as spots placed under glass, which blocked short-wave ultra-violet, showed little or no activity after exposure to daylight in the usual place on the bench for one to four hours.

As the yellow Wratten filters protected the antibiotic activity and gave good light transmission, a suitable source of yellow light was sought for use during experimental work on the antibiotic extracts. Of various sources tried, a Philips yellow dark-room globe was found most satisfactory. Spots exposed up to six hours under this light in a black box showed no reduction in activity. Thus work on this antibiotic mushroom may be safely carried out in this yellow light in an otherwise darkened room.

The conclusion arising from this work is that the main destructive agent for the *Psalliota* antibiotic in crude extracts is bright light. Success can only be achieved by continually protecting it from bright light. Earlier work must therefore be repeated under suitable lighting. Many earlier results have already been checked and purification procedures are being carried out either in the dark or in the yellow light.

Because of its light sensitivity in crude extracts, the antibiotic of *Psalliota xanthoderma* appears to be new and unique. Therefore it may justifiably and conveniently be given the new name psalliotin.

A detailed account of this work will be published elsewhere.

Antibiotic Production by Actinomycetes in Soil demonstrated by Morphological Changes induced in *Helminthosporium sativum*

IT has often been suggested that the production of antibiotics in soil is at least partly responsible for the antagonistic relationships between actinomycetes and plant pathogenic fungi; but little direct evidence has been obtained to offset the fact that these substances have rarely been extracted from soil.

A number of soil actinomycetes were selected for their antibiotic activity towards *Helminthosporium sativum*. These actinomycetes were shown to reduce root-rot of wheat when inoculated simultaneously with the fungus into sterile soil. Reduction in disease incidence was correlated with the degree of antagonism exhibited by the actinomycetes *in vitro*, suggesting that antibiotics were responsible for the disease control. In these experiments we were unable to extract the active antibiotic from the soil, but the possibility remained that antibiotics were present in sufficient concentrations to cause localized effects in soil.

A number of workers have described morphological changes in fungi caused by antibiotics, and it appears that these substances affect the morphological development of a given fungus in a characteristic and reproducible manner[1-4].

In vitro experiments were carried out to determine the effects of the antibiotics produced by the selected actinomycetes on the spores and hyphæ of *H. sativum*. Inhibition of development and morphological changes of the fungus varied with the actinomycete, but the effects noted were quite characteristic. *H. sativum* spores either failed to germinate or were inhibited at a point just subsequent to germination. Antibiotic effects on the hyphæ of *H. sativum* were determined by germinating the fungal spores for twenty-four hours before placing them in the presence of the actinomycetes. Hyphal changes ranged from the stoppage of further mycelial development to such characteristic morphological effects as stunting, distortion or the formation of hyphal protuberances.

To demonstrate the effects of the actinomycetes on *H. sativum* in soil a buried-slide technique was employed[4]. Microscope slides dipped into a plain agar suspension of *H. sativum* spores were placed in pots of sterilized soil inoculated with one of the actinomycetes. In a similar manner the effect on the fungal hyphæ was determined by incubating the agar slides prior to placing in the soil. It was possible to determine the effects of the actinomycetes on the fungus by periodic removal and microscopical examination of the slides. In all cases the characteristic morphological effects caused by the actinomycete antibiotics *in vitro* were noted in the soil. Extraction procedures again failed to demonstrate the presence of antibiotics in the soil.

Further proof of the activity of antibiotics in soil was obtained using the antibiotic actinomycin and *Actinomyces antibioticus*, the organism responsible for its production. In Petri-dish culture both crystalline actinomycin and *A. antibioticus* produce a characteristic swelling, distortion and stunting of the fungal hyphæ. When introduced into sterile soil identical morphological changes are evidenced by *H. sativum* in the presence of either the pure antibiotic or *A. antibioticus*. Extraction of the soil containing the actinomycete yielded no antibiotic, strongly suggesting a localized antagonism due to a relatively high concentration of antibiotic in the immediate vicinity of the actinomycetes.

Isolation and Characterization of Biosynthetic Arylsulphates

ALTHOUGH most phenols are known to be partially excreted as the corresponding sulphate esters, few arylsulphuric acids have actually been isolated from urine, mainly because of the great solubility of the compounds and their sodium and potassium salts. The *p*-toluidine[1] and *p*-bromoaniline[2] salts are less soluble and can be used to isolate arylsulphates after some preliminary purification of the urine[3], but are not very satisfactory when the arylsulphates are present in small amounts.

The findings of Egami[4] that trypaflavin (10-methyl 2 : 8-diaminoacridinium chloride) gave insoluble salts with many different sulphate esters suggested to us that this type of compound might be used to separate arylsulphates from urine. A number of amino-acridines, aminoquinolines and aminopyridines were found to give insoluble salts with arylsulphates, and of the compounds tested 5-aminoacridine was particularly suitable because of its availability and the great insolubility of its readily crystallized arylsulphate salts. The solubilities of these salts in water is of the order of 0·03 gm./100 ml. at 4° C., and they were therefore much less soluble than the *p*-toluidine and *p*-bromoaniline salts mentioned earlier. Unfortunately, the salts do not melt sharply.

A large number of urinary constituents, including some detoxication products, do not give insoluble salts with 5-aminoacridine with the exception of the glucuronides of stilbœstrol and dienœstrol, both of which are known to form relatively insoluble sodium salts[5]. Other compounds which readily gave insoluble 5-aminoacridine salts included dehydro-*iso*androsterone sulphate, di-*iso*propylidene glucose 3-sulphate and the polysaccharide sulphates, carragheenin, laminarin, fucoidin and chondroitin sulphate.

Use has been made of 5-aminoacridine to isolate the monosulphate of 4-chlorocatechol from the urine of rabbits receiving this compound. Methylation of the free hydroxyl group of the 5-aminoacridine salt and identification of the methylated phenol liberated by subsequent acid hydrolysis established the structure of 4-chlorocatechol monosulphate as 2-hydroxy 4-chlorophenyl sulphate. This confirms the suggestion of Dodgson and Williams[6] that sulphate conjugation of 4-chlorocatechol occurred on the hydroxyl group para to the substituent chlorine atom.

An arylsulphate isolated as the 5-aminoacridine salt from the urine of rabbits receiving chlorobenzene, and the monosulphate resulting from the treatment of 4-chlorocatechol with half the theoretical amount of chlorosulphonic acid, were shown in the same way to be identical with the arylsulphate obtained after feeding 4-chlorocatechol.

A detailed account of this work will be published elsewhere.

Effect of Temperature on the Inactivation of Phage labelled with Phosphorus-32

IN the course of investigations on phage *BM* labelled with phosphorus-32, we have had occasion to study its inactivation at a temperature of 2–4° C. and at that of 'dry ice' (– 79° C.). In this way an effect of temperature on the rate of inactivation has been observed, a result which may be of interest in wider investigations recently made by various authors[1] on the combined effects of temperature and ionizing agents on viruses and protein molecules.

The investigation has been carried out with the phage *BM* active on *Bacillus megatherium* which has been studied for some years in our laboratory[2]. The labelled phage was prepared by infecting cells of *B. megatherium* which had been grown in semi-synthetic medium containing about 3 mc. of phosphorus-32

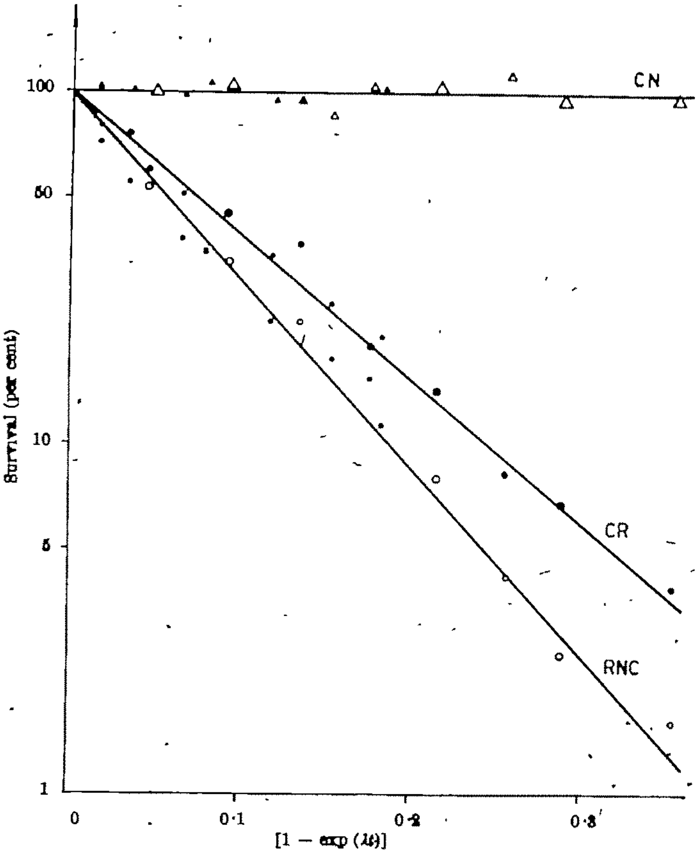

Fig. 1. RNC = labelled phage not frozen (2° C.), equation being $y = \exp\{-12\cdot 3\,[1 - \exp(-\lambda t)]\}$; CR = labelled phage frozen (− 79° C.), equation being $y = \exp\{-9\cdot 3\,[1 - \exp(-\lambda t)]\}$; CN = unlabelled phage frozen (− 79° C.). The three sizes of circles and triangles represent respectively the weighted mean values of three experiments, weighted mean values of two experiments and the values of one experiment respectively

per ml. and with a phosphorus-32/phosphorus-31 ratio which varied from 1×10^{-3} to 4×10^{-4} in the various experiments. The concentration of the phage obtained in this medium was 10^{10} particles per ml. of labelled phage, with an increase by a factor of 10^{3} with respect to the unlabelled phage introduced for the infection.

Immediately after the lysis, dilution to about 10^{-4} is carried out with broth to exclude any action of the unassimilated phosphorus-32.

The phage particles obtained under these conditions undergo a rapid inactivation caused by the decay of the phosphorus contained chiefly in their deoxyribonucleic acid. According to Hershey *et al.*[3], this inactivation can be attributed largely to the transformation of phosphorus-32 to sulphur-32, which takes place in the genetic structures of the phage, and only to a negligible extent to the passage of the β-particles through the vital structures.

Samples of radioactive phage suspended in broth were frozen to − 79° C. by techniques which will be described in a later publication, and kept at this temperature for days or weeks. Samples of non-radioactive phage were also frozen by the same procedure, and from Fig. 1 it is evident that the technique adopted excludes any mortality due to freezing.

Samples were taken periodically to check the value of the inactivation and for control. At the same time suspensions of radioactive phage were kept at a temperature of 2–4° C. and tested periodically for inactivation.

The duration of our experiments, the temperature and the medium in which the particles were suspended exclude any mortality independent of the radioactivity.

As can be seen clearly from Fig. 1, our results (which refer to three experiments giving very consistent results) suggest a highly significant difference in the rate of inactivation, a difference which can be calculated as about 25 per cent less for the frozen radioactive phage.

This difference can be attributed to various possible causes including: (1) a diminished rate of diffusion of the toxic ions produced by β-rays inside the phage particles when kept at a low temperature and in the solid state; in fact in this case toxic ions produced inside non-sensitive structures tend to remain localized and have no lethal effect in structures farther away[4]; (2) a lower production at low temperatures by electrons of hydrogen peroxide, with a consequent diminution of the lethal action[5]; (3) a contraction of the sensitive structures[4]; that is, a decrease with temperature of the length of certain chemical bonds with a consequent increase in their stability with respect to β-ray action and a decrease of the radiosensitive volume.

Since the effect of temperature observed by us cannot in any event be attributed to radioactive decay, it suggests that the transformation of phosphorus-32 to sulphur-32 contributes only to a limited extent, which cannot be evaluated at present, to the causes of death. The experiments now in progress on the inactivation of labelled *BM* phage after its penetration into unlabelled cells may give more suitable results for this evaluation.

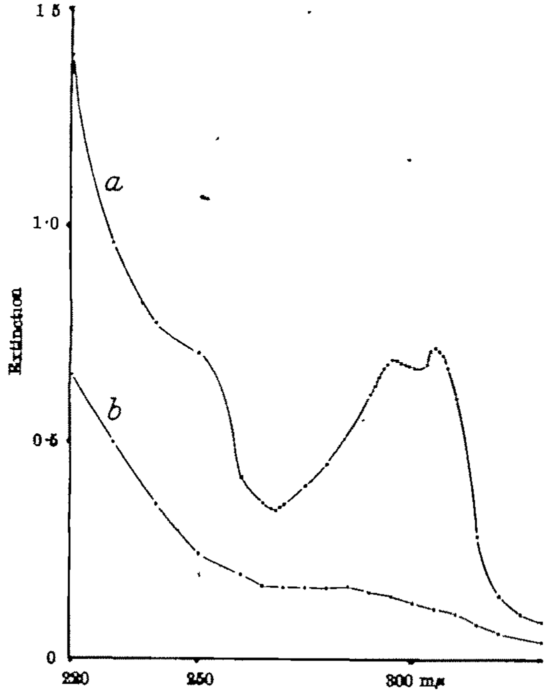
A Constituent of Male Sperm Antagglutin related to Vitamin E

Through a number of unknown factors in the male and the female genital apparatus, the head surface of mammalian spermatozoa is influenced in such a way as to bring about agglutination. This state of the cell surface is probably in some way important for the fusion at fertilization. On the other hand, agglutinated spermatozoa are unable to fertilize[1], and the tendency to agglutinate is normally opposed by a special protein produced in the prostatic gland. This was called 'sperm antagglutin'[2]. From this



proteid a group may be split off with the same biological potencies as the native substance. Sperm antagglutin, as well as its active group, occurs in reduced and oxidized forms, which may be reversibly transformed into each other. In both cases only the reduced form is biologically active. The active group was shown, *inter alia*, to contain sugar[3] and probably also sulphuric acid residues[3].

Further, we have now isolated from male sperm antagglutin a substance which is very slightly soluble in water and easily dissolved in ethanol and ethyl ether. The general type of the extinction curve of this substance in ethanol (Fig. 1*a*) very nearly conforms to that of α-tocopherol in hexane (cf. ref. 4). Oxidation with nitric acid according to Ungnade and Smith[5] yields a yellow colour, however, with the absorption maximum at 405 mμ, typical of the red oxidation product of α-tocopherol[6]. When dissolved in *n*-hexane, the conventional solvent for spectroscopical examinations on this group of substances, the material showed an extinction curve of quite another type (Fig. 1*b*). Samples brought back into ethanol after being examined in *n*-hexane give extinction curves the form of which was now exactly the same as in hexane. This indicates the occurrence of some interaction between the substance in question and some constituent of the 'hexane'. This change of the extinction curve was brought about by all kinds of commercial *n*-hexane (also that "for spectroscopical use" from the British Drug Houses, Ltd.). Only when freshly purified hexane was used was the change more or less reversible.

Under certain conditions a product with absorption maxima at 292 and 325 mμ in ethanol has been obtained, showing the same type of curve in *n*-hexane. In this solvent the maxima are at 289 and 315 mμ. Postulating a corresponding displacement of the maxima of curve *a* in Fig. 1 in the transfer from ethanol to *n*-hexane, these two maxima would be expected to occur at 292 and 298 mμ in the later solvent. These figures are identical with those given for α-tocopherol in *n*-hexane (cf. ref. 4).

This tocopherol derivative probably is the reversibly oxidized and reduced component of the male sperm antagglutin and its active group. The abolition of the absorption maxima in hexane gives a clue as to the mechanism by which those of tocopherol are being suppressed in the native antagglutin (cf. Fig. 1 of ref. 2).

A Comparison of some Natural and Synthetic Melanins

The identity of natural and synthetically prepared melanins is still not proved[1–3]. My investigations suggest that some of the members of these two classes of melanins possess a similar structure.

Preparation *A* was a natural melanin prepared from the choroid of the ox eye. After careful removal, the choroids were refluxed with 2 *M* hydrochloric acid for 50 hr. Most of the tissue dissolved to give a yellow solution, whereas the pigment remained as an acid-insoluble, red-brown mass. This was dissolved in 5 *M* sodium hydroxide. Some of the acid-insoluble residue did not dissolve in the alkali and was discarded. The alkaline solution was acidified with hydrochloric acid, whereupon the pigment was precipitated. Repeated solution in *M* sodium hydroxide and reprecipitation with acid, followed by washing with distilled water, was performed until a constant nitrogen percentage was obtained from the dry precipitate. Three such precipitations were usually sufficient to obtain such constancy. The final precipitate was redissolved in 0·01 *M* sodium hydroxide.

Preparation *B* was a synthetic melanin prepared by the autoxidation of β-3 : 4 dihydroxyphenylalanine ('dopa') according to Arnow[4]. A thrice-reprecipitated preparation was used. This was considered to be the purest melanin and was used as a standard. The pigment was dissolved in 0·01 *M* sodium hydroxide.

Preparation *C* was a synthetic melanin prepared according to Raper[5] from tyrosine, using potato tyrosinase buffered at *p*H 6·8.

Preparation *D* was a synthetic melanin prepared from tyrosine and potato tyrosinase buffered at *p*H 7·4. In both *C* and *D* a thrice-reprecipitated preparation was obtained and was dissolved finally in 0·01 *M* sodium hydroxide.

Fig. 1 shows the ultra-violet absorption spectra (obtained using a Beckman spectrophotometer) of the sodium hydroxide solutions of the four melanins. A 'bump' in the region of 270 mμ is just noticeable in curves for *A* and *B*, whereas those for *C* and *D* show

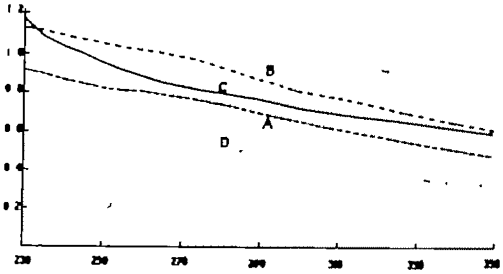

Fig. 1

a bump at 285 mμ. The *p*H has little effect on the shape of the curve.

Such a bump is also evident in the absorption curves of the melanin from dihydroxyphenylalanine of Clemo *et al.*[3], and in those for melanin from tyrosine of Florence *et al.*[6], but was not commented upon by these workers. Bowness *et al.*[7] obtain similar bumps (at 280 mμ) using an enzymic oxidation procedure, but ascribe them to the presence of dihydroxyphenylalanine. Mason[8] showed, however, that solutions of dihydroxyphenylalanine do not possess such an absorption maxima after a short exposure to air, an observation confirmed during the present work. The similar bump in the curve for the natural melanins is not depicted on the curves for preparations made by Florence *et al.*[6], presumably due to masking by contaminants in a less pure preparation.

The curves obtained here suggest that melanin from dihydroxyphenylalanine and the natural melanin have a similar chemical structure which, however, appears to differ from that of melanin prepared enzymatically from tyrosine, whether the latter is prepared in an acidic or an alkaline medium. It appears likely therefore that the enzymic oxidation of dihydroxyphenylalanine and the aerobic autoxidation of this substance involve different reaction sequences, and that a reaction sequence similar to the aerobic autoxidation is followed by dihydroxyphenylalanine during its oxidation in the environment of the ox eye choroid.

Further work in progress indicates that a melanin, prepared in a manner similar to the above, from human black hair, has an almost identical absorption spectra to that of the melanin isolated from the ox choroid. It exhibits a similar bump at 270 mμ. Thus melanin from dihydroxyphenylalanine, from ox choroid and from human black hair, appear to be formed by similar reaction sequences.

I wish to thank Prof. Joseph Gillman for suggesting this problem to me, and to thank him and Drs. P. R. Levy and G. N. Festenstein for their advice and criticism.

Ketose Oligosaccharides in the Apricot Fruit

OLIGOSACCHARIDES composed of glucose and fructose units have been detected by various workers recently in extracts of Jerusalem artichoke, wheat flour, barley and agave. A number of oligosaccharides which are hydrolysed by invertase to glucose and fructose have now been found in ripe apricots. In one case a hexitol was also detected in the hydrolysis products.

A de-ionized aqueous solution was prepared from an 80 per cent alcoholic extract of apricot fruit (variety, Trevatt). Aliquots were chromatographed on a cellulose column using *iso*-propanol–*n*-butanol–water (7 : 1 : 2), or on a charcoal column using increasing concentrations of aqueous ethanol; the fractions containing oligosaccharides were re-run on charcoal columns. It then became clear that at least six ketose oligosaccharides were present.

The predominant oligosaccharide (*K*3; see Table 1) was present in sufficient quantity to be detected on paper chromatograms of the original fruit extract. It appeared to be homogeneous after the second fractionation on charcoal but did not crystallize. The dried syrup (yield, 0·07 per cent of the fresh fruit) had an optical rotation $[\alpha]^{20}_{D} = 24\cdot3°$ (c. 4·94 in water). The sugar behaved like a trisaccharide on charcoal columns and paper chromatograms. It was hydrolysed by invertase to glucose and fructose, which were separated on paper and estimated with anthrone[1]; the ratio glucose : fructose was 1 : 2. Hydrolysis with *N* sulphuric acid at 100° C. for 4 hr. also gave glucose and fructose; with 20 per cent acetic acid for 4 hr. at 50° C., glucose, fructose and sucrose were formed. The sucrose was eluted from paper chromatograms and its identity deduced from hydrolysis with invertase, R_F values, and colour reactions. *K*3 is probably a trisaccharide of the type O-α-D-glucopyranosyl-(1→2)-O-β-D-fructofuranosyl-(?)-β-D-fructofuranoside. The β-fructose link is deduced from the known specificity of yeast invertase. Two similar trisaccharides have been isolated recently from the sugar mixtures obtained by the partial hydrolysis of sucrose with yeast invertase[2] and mould invertase[3]. These are O-α-D-glucopyranosyl-(1→2)-O-β-D-fructofuranosyl-(6→2)-β-D-fructofuranoside, (kestose, $[\alpha]^{20}_{D} = +27\cdot3°$)[2], and O-α-D-glucopyranosyl-(1→2)-O-β-D-fructofuranosyl-(1→2)-β-D-fructofuranoside ($[\alpha]_D$ between + 30·5 and 32·6°)[3]. The apricot sugar, *K*3, ran farther on paper chromatograms than the major component (presumed to be kestose) in a mixture obtained by the partial hydrolysis of sucrose with yeast invertase; it has not been compared with pure kestose.

The other ketose oligosaccharides were further purified by elution from paper chromatograms developed with ethyl acetate–pyridine–water (8 : 2 : 1). Their R_G values are recorded in Table 1. With the exception of *K*1, they were all non-reducing (3 : 5-dinitrosalicylic acid reagent). The action of invertase on *K*1 gave, as well as glucose and fructose, a substance which, from R_F values and reactions on paper, appeared to be a hexitol (probably sorbitol). *K*1 has now been resolved, by a long run in *n*-butanol–acetic acid–water (4 : 1 : 1), into two components (R_G = 0·72 and 0·86), both containing fructose, the component with the lower R_G value being a reducing compound.

The oligosaccharides from the apricot (*K*1–*K*6) were compared directly on paper chromatograms with

Table 1. R_g* VALUES OF APRICOT OLIGOSACCHARIDES IN TWO SOLVENTS

Oligosaccharide designation†	R_g	
	n-Butanol–ethanol–water (10 : 1 : 2 v/v)	Ethyl acetate–pyridine–water (8 : 2 : 1 v/v)
*K*1‡	0·74	0·66
*K*2	0·29	0·21
*K*3	0·41	0·24
*K*4	0·40	0·45
*K*5	0·22	0·17
*K*6	0·17	0·12

* Ratio of the distance travelled by the oligosaccharide to the distance travelled by sucrose, the spots being superimposed on the starting line.

† Numbered in order of displacement from a charcoal column.

‡ *K*1 was not resolved by these solvents.

those synthesized from sucrose by yeast invertase (components I–IV[4]) and *K*2, *K*4, *K*5 and *K*6 were shown to differ from the sucrose-invertase products. *K*3 and component II had the same *Rg* values in several solvents; but this is of small significance as component II is a mixture of two sugars[5] unresolved by paper chromatography.

The occurrence of these fructose-containing oligosaccharides in the apricot suggests the presence of a transfructosidation system. Similar oligosaccharides in the artichoke are apparently formed by enzymic transfer of fructose from inulin to sucrose[6]. In the apricot, sucrose itself is the most likely source of fructosyl radicals.

There are indications that some of these oligosaccharides occur in other fruits. A ketose with an *Rg* value similar to that of the *K*1 mixture has been detected on paper chromatograms of pear sugars, and traces of a ketose similar to *K*3 have been found in extracts of some pears and peaches.

Occurrence of Fatty Acids with Uneven-numbered Carbon Atoms in Natural Fats

ALTHOUGH the occurrence in natural fats of fatty acids containing odd-numbered carbon atoms, including *n*-heptadecanoic acid and *n*-pentadecanoic acid, has been claimed by various investigators, subsequent work has invariably revealed that such acids are actually equimolecular mixtures of adjacent members of even-numbered fatty acids. The generally accepted view at the present time is expressed by Hilditch[1] as follows: "With the solitary exception of isovaleric acid (found only in the depot fats of the dolphin and porpoise) the molecules of all natural straight-chain fatty acids, saturated or unsaturated, contain an even number of carbon atoms". Work in this laboratory, however, suggests that this view is not correct, and that fatty acids containing odd-numbered carbon atoms do, in fact, occur in some natural fats.

Following the isolation of pure *n*-heptadecanoic acid from hydrogenated mutton tallow as previously described[2], we have now prepared pure *n*-pentadecanoic acid from the same source as well as from hydrogenated shark (*Galeorhinus australis*) liver oil. It has also been shown[3] that hydrogenated ox perinepheric fat contains a consecutive series (including odd-numbered carbon acids) of volatile acids from C_4 to C_{18}. This indicates the probable presence of normal uneven-numbered saturated or unsaturated acids in natural fats. Further, without recourse to hydrogenation, pure *n*-pentadecanoic acid has been isolated from butter-fat.

This work is still in progress, and the detailed results will be published elsewhere.

Basic Amino-acids of Silk Fibroin

IN studies of the constitution of proteins, the basic amino-acids are of particular interest. With silk fibroin, for example, the basic amino-acids are the least frequent of the constituent amino-acid residues and are therefore indicative of the approximate minimum molecular weight. Coleman and Howitt, deduced from the available analytical data that, assuming the molecule to contain one histidine residue, there was present a total of some 390 residues which, accepting the experimental mean residue weight of 78, implied a molecular weight of approximately 30,000; a molecular weight of this order was found by osmotic pressure measurements made on the renatured protein. In the latter connexion, however, Holmes and Smith[2], by ultracentrifuge and diffusion methods, found a mean molecular weight of 60,000–150,000 (average 84,000) for water-soluble fibroin. This higher value of the mean molecular weight suggests that, assuming no great error to exist in the value of about 0·4 per cent for the histidine content of fibroin, there are at least two histidine residues in the fibroin molecule. In order to strengthen the available experimental evidence on this point, a careful determination has been made of the basic amino-acids in silk fibroin.

A sample of degummed silk (*Bombyx mori*) was exhaustively extracted with the azeotropic mixture of benzene and methanol, repeatedly washed with distilled water, and finally air-dried. Two samples of about 1·0 gm. were accurately weighed and hydrolysed by refluxing with 25 ml. of 5 *N* hydrochloric acid for 24 hr.; a third sample was examined for moisture content. Hydrochloric acid was removed from each of the hydrolysates by distillation *in vacuo* and the residue made up to 10 ml. with distilled water. Aliquots (0·20 ml.) equivalent to 20 mgm. of the original silk fibroin were fractionated on a 0·9 cm. × 15 cm. 'Dowex 50' ion-exchange resin column under the conditions described by Moore and Stein[3] for the separation of basic amino-acids, 2 ml. fractions being

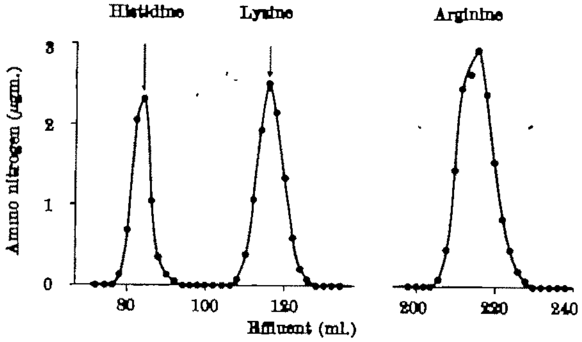

Fig. 1

collected. The histidine, lysine and arginine peaks thus obtained are shown in Fig. 1; the ammonia peak appearing between lysine and arginine was not estimated.

Two determinations were made on each of the two hydrolysates and gave the following values (corrected to a dry protein basis):

	Amino-acid (gm.)/100 gm. of fibroin
Histidine	0 370 ± 0 008
Lysine	0 537 ± 0 006
Arginine	1 000 ± 0 007

These values correspond (within ± 4 per cent) to an integral molecular ratio of 2 : 3 : 5, and indicate that the molecular weight of fibroin is of the order of 84,000 and that the number of amino-acid residues in the molecule is slightly greater than 1,000 (for an equivalent residue weight of 78); this agrees with the value for the molecular weight found by Holmes and Smith[2].

Olefinic Nature of Anacardic Acid from Indian Cashew-nut Shell Liquid

ANACARDIC acid, the major component of the liquid extracted by solvent from cashew-nut shells[1], was regarded as a homogeneous chemical entity containing in its aliphatic side-chain of fifteen carbon atoms two double bonds until recently, when it was shown by Izzo and Dawson[2] to be in fact a mixture of olefinic components of which they identified the mono-olefin in the form of a crystalline glycol of the methylated anacardic acid. The present communication reports the complete separation of the mixture into its several components and the determination of their olefinic structure.

A sample of anacardic acid, prepared from Indian cashew-nut shells, was subjected to fractional crystallization, using as solvents acetone, methanol and petroleum ether, at temperatures of 0° to − 80° C., whereby pure specimens of four components were isolated, namely, a saturated one, and a mono-, di- and tri-olefin.

The saturated component (m.p. 91·5° C.)[3] was identified as 1-hydroxy 2-carboxy 3-pentadecyl benzene from a mixed melting-point determination with a pure sample of the compound obtained by catalytic hydrogenation of anacardic acid and carbon-hydrogen analysis.

Oxidation of the mono-olefin (m.p. 44–45° C.) with potassium permanganate in acetone gave azelaic, heptylic and oxalic acids, from which its structure was deduced as 1-hydroxy 2-carboxy 3-(8′ pentadecenyl) benzene, identical with the olefinic structure reported previously[3].

The di-olefin (m.p. 25–26° C.) on oxidation with permanganate in acetone at − 20° C. gave azelaic, butyric and oxalic acids. Further, the monophenol obtained by decarboxylation of the acid at low pressure, on methylation and subsequent oxidation with permanganate, yielded ω-(3-methoxy phenyl) caprylic acid[4,5], and butyric and oxalic acids. From these results, the di-olefin was assigned the structure 1 - hydroxy 2 - carboxy 3 - (8′,11′ pentadecadienyl) benzene.

A similar oxidation of the tri-olefin yielded azelaic, oxalic and formic acids; the methyl ether of the decarboxylated sample resulted, on oxidation, in ω-(3-methoxy phenyl) caprylic acid, and oxalic and formic acids. Tests for presence of conjugated double bonds were negative. On the basis of these observations, the tri-olefin was given the structure 1-hydroxy 2-carboxy 3-(8′,11′,14′ pentadecatrienyl) benzene.

A comparison of these results with those obtained recently on the monophenol from commercial cashew-nut shell liquid[5] points to the identity of the olefinic characteristics of the solvent-extracted and the commercial liquids. The composition of the heterogeneous mixture of the anacardic acid studied by us was found, on the basis of a typical careful fractionation, to be: saturated component, 4; mono, 15; di-, 44; and tri-olefin, 37 per cent.

A full account of this investigation will be published elsewhere.

Bacterial Soft Rot of Avocado Fruit

SOFT-ROT diseases of avocado fruit are recorded in the literature as associated with fungi. So far, the only bacterial disease reported to affect avocado fruit is a dry rot caused by *Pseudomonas syringae* Van Hall[1]. In December 1953, however, a bacterial soft-rot disease in avocado fruits was found in Israel on several fruits picked from a single tree of the Californian variety, H. L.

In infected specimens of unripe, hard, green fruits a third or more of the fruit area had been turned dark and soft by a spreading decay. The flesh underlying such areas was soft, light to dark-brown in colour, and smelled putrid. Microscopic examination of Gram-stained affected tissues revealed numerous Gram-negative rod-shaped bacteria.

The organisms were isolated in pure culture on nutrient agar + 1 per cent glycerol plates and a distilled water suspension of 48-hr. old slant cultures was made. Healthy unripe fruits were inoculated by pricking through drops of the suspension placed on the fruit surface, and were kept in bell-jars over water at temperatures of 14–37° C. Within four to eight days, inoculated fruits developed lesions similar to those found on the original specimens. The lesions appeared as soft, dark, flat spots which spread far beyond the centre of inoculation. The spots coalesced and covered the entire fruit eight to nine days after inoculation at 32° C. Infection experiments with re-isolations from lesions gave similar results. No infection resulted when drops of suspension were not pricked into the fruit. Controls pricked through drops of sterile distilled water did not develop any sort of infection. Various vegetables inoculated with the organism under laboratory conditions developed a typical soft rot of the parenchyma ; no infection was induced on avocado leaves, or on lemon fruits.

The organism is closely related morphologically, physiologically and pathologically to the group of organisms originally identified as *Erwinia aroideae* (Townsend) Holland[1], and later identified by Rudd Jones, Dowson and others as a non-gas-forming strain of *Bacterium carotovorum* (L. R. Jones) Lehmann and Neumann[2], or *Erwinia carotovora* (Jones) Holland[3]. Like other organisms of this group, it is a wound parasite and requires relatively high humidity to induce infection. Its optimal growth and pathogenicity temperature is 30–32° C. ; no infection occurs above 38° or below 12° C. ; good, though slow, infection is induced at 14° C., and very good infection is produced at 36–37° C.

A detailed report on this organism and on other isolates of *E. carotovora* and *E. atroseptica* (Van Hall) Jennison will be published elsewhere.

'Browning' Reactions in Freeze-dried Extractives from the Skeletal Muscle of Codling (*Gadus callarias*)

TARR[1-3] has shown that the 'browning' of flesh observed in many Canadian fish species when autoclaved for 1 hr. at 120° C. results from a Maillard reaction[4] between the various muscle amino-compounds and reducing sugars—primarily ribose. The present communication reports a study on the 'browning' of extract preparations of codling muscle under milder conditions such as are encountered during vacuum contact plate drying of fillets[5], dry salting and the storage of dehydrated codling muscle.

Codling muscle (1 hr. post mortem at 15° C.) was repeatedly extracted into cold 75 per cent v/v ethanol. Chloroform was added to the filtered extract to 75 per cent v/v and the emulsion shaken for ten minutes. After separation the upper, aqueous layer was freeze-dried. This preparation contained more than 90 per cent of the free amino-acids[6] and 70 per cent of the muscle reducing substances as determined by copper reduction. (Parallel chloroform separations of hexose and pentose sugar solutions in 75 per cent ethanol gave freeze-dried preparations with recoveries of the same order as amino-acids.) The white, deliquescent powder was ground at – 30° C. and stored over phosphorus pentoxide under high vacuum at 0° C. A yield of 1·9 per cent powder was obtained : nitrogen content, 13·72 per cent ; reducing activity, 1·60 per cent glucose equivalent.

The nitrogenous fraction was found to include (nitrogen basis, per cent in powder): creatine + creatinine, 6·2 ; trimethylamine oxide, 3·2 ; taurine, 1·7 ; anserine, 0·98 ; volatile amine, 0·365 ; aspartic acid, 0·041 ; glutamic acid, 0·055 ; glycine, 0·24 ; serine, 0·026 ; α-alanine, 0·10 ; β-alanine, 0·051 ; lysine, 0·061 ; histidine, trace ; 1-methylhistidine, 0·062 ; proline, trace ; valine, 0·020 ; leucine, 0·033 ; cysteic acid, 0·05 ; glutathione, trace ; phosphorylethanolamine, trace ; glucosamine, trace ; tyrosine, trace ; threonine, trace. Chromatography failed to detect free ribose. Traces of glucose, glucosamine and another compound, probably galactose, were found, but most of the reducing substances remain to be identified. Few observations are available on phosphorylated glycolysis intermediates in fish muscle, and some of these are probably implicated. Tarr[1] has shown that addition of hexose phosphates increases browning in fish muscle at high temperatures.

Effect of water relations on browning. Tubes containing 20 mgm. freeze-dried extractives were equilibrated[7] in bottles of different relative humidities over a complete range given by phosphorus pentoxide, sulphuric acid – water mixtures and water. Such systems turned first pink and then brown in colour, changes strictly analogous to those found in intact fillets dried during storage. Fig. 1 illustrates typical effects of relative humidity and temperature on browning as estimated by the optical densities of diluted reaction-mixtures at 430 mμ. In the experiment at 25° C., the overall reaction series had not proceeded so far as those at 60° C., which gave poorer definition at 'peak' level but showed a marked shift of peak towards higher relative humidities. At both temperatures the peak was at a lower relative humidity than the 70 per cent reported by Lea and Hannan[7] for simple glucose–casein mixtures. Fig. 2 illustrates a 'browning' nitrogen concentration curve calculated from water uptake/relative humidity data obtained in other 60° C. experiments at a 100 mgm. extractive level. An extension for lower concentrations was obtained from experiments with extractive

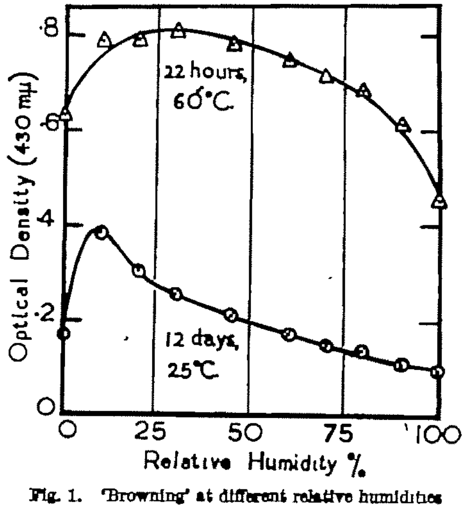

Fig. 1. 'Browning' at different relative humidities

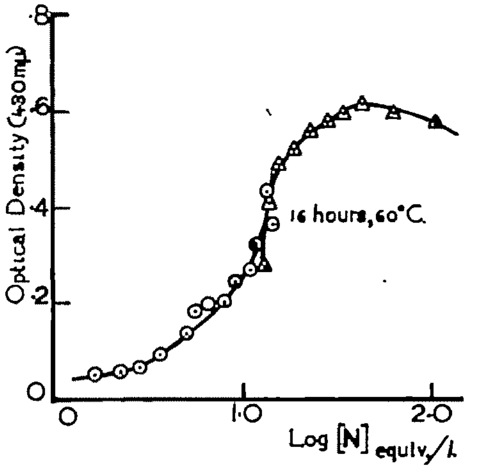

Fig. 2. 'Browning' at different concentrations of reactants

solutions at the same temperature and time in sealed tubes. This form of curve appears to be of greater value in relation to implications for the browning of whole fish than those in Fig. 1, as the linear uptake/relative humidity relation found for extractives differs appreciably from a sigmoid curve reported for intact muscle[8].

Effect of temperature. Aliquots of freeze-dried extractive solution (0·69 NN), with a drop of chloroform to inhibit bacterial growth, were allowed to react in sealed tubes at different temperatures. Table 1 shows that 'browning' is highly dependent on temperature under these conditions. Figures relate to the initial linear sections of 'browning'/time curves.

Table 1 'BROWNING' AT DIFFERENT TEMPERATURES

Temperature (° C.)	Units optical density increase/hr.
0°	$2·97 \times 10^{-5}$
15°	$6·30 \times 10^{-4}$
37°	$2·00 \times 10^{-2}$
60°	$3·01 \times 10^{-1}$

These figures give an approximately linear plot for $\log_{10}$ 'browning' rate/reciprocal absolute temperature.

Effect of pH. Solutions of the preparation had a pH of 6·8 and were strongly buffered. This accounted for the percentage 'volatile' amine held in salt form. Preliminary results indicate that 'browning' is at a maximum at pH 7 at 60° C. This has not been the finding with simple sugar – amino-acid[6] and sugar – protein[7] mixtures, and can be accounted for by a loss of reactive volatile amine from the reaction phase at higher pH levels. Such behaviour may well represent an important practical difference between such reactions of simple mixtures and complex volatile amine-containing systems.

Uptake of Phosphorus-32 by Mycorrhizal Plants

INVESTIGATIONS based on chemical analyses have indicated that the absorption of phosphorus by pine seedlings is increased by the presence of ectotrophic mycorrhizas[1]. Harley *et al.*[2] have shown, however, that when labelled phosphorus is supplied to excised roots of beech the presence of a mycorrhizal sheath presents a partial barrier to phosphorus uptake by the tissues of the root. This communication reports the result of an experiment in which phosphorus-32 was used to indicate how far the mycorrhizal habit influences the uptake of phosphorus by intact plants of *Nothofagus menziesii* (mycorrhizas ectotrophic, typical of the Fagaceae) and *Pinus radiata*. The presence of mycorrhizas had no apparent effect on the rate of growth of these two species under the conditions employed in the experiment.

Individual mycorrhizal and non-mycorrhizal seedlings were transplanted in February, 1954, into separate glass pots containing 360 gm. (moist weight) of a chemically sterilized meadow loam of pH 5·3, known to be deficient in phosphates. Six weeks later all the plants were supplied with radioactive phosphorus. This was added to the soil as 200 ml. of a solution in distilled water. Two concentrations were employed to give activities of 50 μc. and 100 μc. per pot, respectively. After fourteen days the leaves of the plants were assayed for relative activity.

For each of the two species, comparable samples of leaf tissue were obtained by taking equal numbers of leaf segments (thirty segments, 2 cm. in length) in *Pinus*, or equal numbers of leaf disks (twelve disks, 5 mm. in diameter) in *Nothofagus*, from the upper leaves of the plant. The leaf segments or disks, representative of each plant, were arranged beneath an end-window Geiger–Müller counter connected to a 'Dynatron' electronic scaling unit.

Table 1 RELATIVE ACTIVITY (IN COUNTS PER MINUTE) OF LEAF SAMPLES FROM MYCORRHIZAL AND NON-MYCORRHIZAL PLANTS SUPPLIED WITH PHOSPHORUS-32

Phosphorus-32 per pot	*Pinus*		*Nothofagus*	
	Mycorrhizal	Non-mycorrhizal	Mycorrhizal	Non-mycorrhizal
50 μc.	59 457 128 765 536	11 0 9 0 1 0	7 64 22 95 18	41 1 0 28 44
100 μc.	1,003 215 193 879 1,584	12 13 2 1 5 3	293 8 199 28 37	64 0 26 72 61

Table 1 shows that in *Pinus*, despite the variability between plants, the leaves from the mycorrhizal plants were, without exception, markedly more active than those from non-mycorrhizal plants. In *Nothofagus*, however, no similar consistent difference was observed. The results indicate that the mycorrhizal habit enhanced the uptake of phosphorus to the leaves in seedlings of *Pinus*, while exerting relatively little influence on this process in seedlings of *Nothofagus* grown under the same conditions.

Antagonist Inhibition as the Earliest Sign of a Sensory-Motor Reaction

REACTION time is defined as the interval of time between a sensory (optic, acoustic, tactile, etc.) stimulus and the voluntary reaction of muscular contraction. The values of reaction time for a given sensory-motor reaction show the smallest variation when the subject is alertly expecting the sensory stimulus. Even so, there is considerable variation of reaction time between different subjects. Individual differences are of less interest, however, than the lowest value of reaction time obtainable in optimal circumstances if the minimum time of cortical integration for a sensory-motor reaction is to be studied. The time of cortical integration is obtained by subtracting the afferent and efferent conduction times from the reaction time[1].

So far, only the electrical or mechanical manifestations of muscular contraction in agonists have been studied as examples of voluntary reaction[2]. We have undertaken a study of the simultaneous changes in muscles antagonistic to the voluntary movement of the reaction.

In our experiments, the sensory stimulus was evoked by an electric shock to the N. medianus in the fossa cubiti, of a strength which gave only a tactile perception. The electrical activity of the M. biceps and triceps of the same arm were separately recorded by means of an electroencephalogram apparatus (Schwarzer). The subject held his M. biceps in strong tonic contraction and reacted to the sensory stimulus by a contraction of his M. triceps.

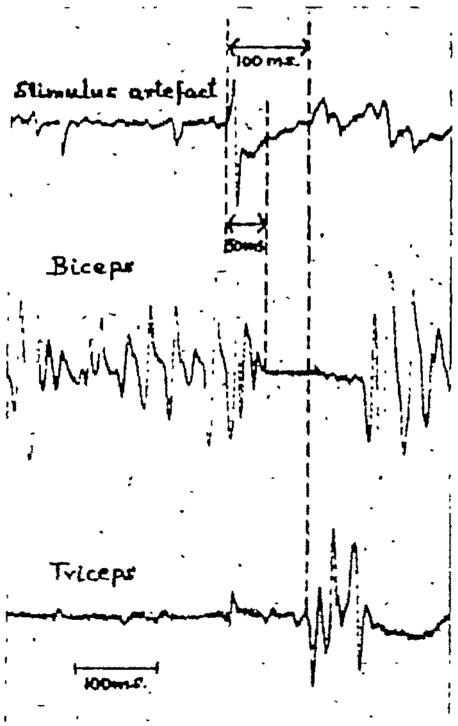

Fig. 1

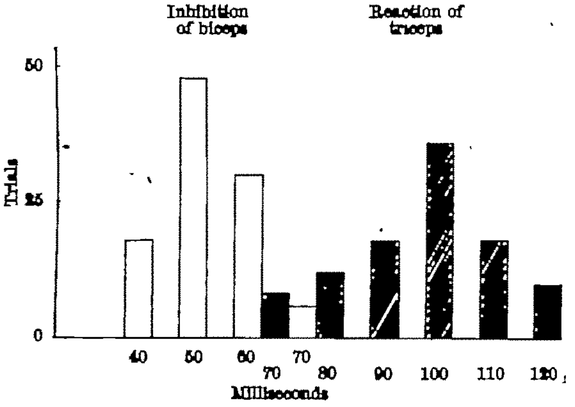

Fig. 2

With this arrangement, the voluntary reaction of triceps contraction was usually preceded some 50 m.sec. earlier by inhibition of the tonic biceps contraction (Fig. 1). Fig. 2 shows in diagrammatic form the reaction times for antagonist inhibition and agonist contraction. The reaction time for antagonist (biceps) inhibition may be as short as 40 m.sec.—a surprisingly low value if the reaction is accepted as being cortically integrated (voluntary). The antagonist reaction could scarcely be an example of spinal reciprocal inhibition[3]; it is interpreted by us as part of the voluntary reaction, although the actual inhibitory influence may be exerted at the cortical or spinal level.

The afferent conduction time from the peripheral nerve to the sensory-motor cortical area has been estimated as about 18 m.sec. (after Dawson[4]). The efferent conduction time, from the motor cortex to the peripheral muscle, has been estimated as at least 12 m.sec., due regard being taken to interneuronal spinal transmission (Lloyd[5], cf. ref. 6). By subtraction, an interval of only 10–20 m.sec. is left for cortical integration of the reaction of antagonist inhibition. This time interval is of the same order of magnitude as the duration of an 'evoked potential'[7].

The present observations therefore indicate that even a voluntary sensory-motor reaction may take place within restricted cortical fields without necessarily engaging more complicated cortical or subcortical reverberating circuits.

A detailed description of the results will appear in the *Zeitschrift für Biologie*. The investigation was supported by a grant from the Deutsche Forschungsgemeinschaft.

A Simplified Method for spreading the Chromosomes in the Rabbit Blastocyst

It is well known that great difficulties are involved in counting the exact chromosome numbers from mammalian species which have a large number of chromosomes. In the past decade different results have been presented which indicate a variation in the chromosome number in different tissues even within a single mammalian species, including man[1]; but in many cases the variation shown is apparently a result of errors in the counting or in the technique used, for example, in making squashes, or in both as discussed by Fischberg and Beatty[2] and Venge[3].

For some years we have been studying the variation in the chromosome number in the rabbit, in testicular tissue as well as in blastocysts. During the course of the experiments it became clear that much of the variation in the chromosome number was due to counting errors if only gentle squashes were applied; but if the squash was made with a high pressure in a vice, mechanical disturbances were introduced[3]. We therefore tried to find a method of spreading the chromosomes without breaking the cells.

Continuing our experiments, we treated rabbit blastocysts in saline solutions of different concentrations for twenty minutes at a temperature of 37° ± 1°, with the result that many more cells could be used for counting the number of chromosomes (Table 1).

Table 1. NUMBER OF CELLS COUNTED IN TREATED BLASTOCYSTS

Concentration of sodium chloride	0	0·30	0·45	0·67	0·90 per cent
No. of blastocysts	2	19	44	27	24
No. of cells counted	1	186	425	147	21
No. of cells per blastocyst	(0·5)	9·8	9·7	5·4	0·9

We are aware that subjectivity enters into the decision whether a cell should be counted or not. However, once the decision was made, the cell was used in the chromosome counts. The results indicate the increase in number of countable cells due to our method.

By the treatment in the hypotonic solution and applying squash in making the preparation the spindle is disturbed; but the split between the chromatids is not so exaggerated as described by Manna[4]. In Fig. 1 is shown a metaphase plate where the chromosomes are well spread due to treatment of the blastocyst in 0·45 per cent solution. Only a gentle squash was applied. The chromosome number (44) is easily counted. The risk of producing artefacts is in our experience very small. In addition, the staining of the chromosomes is often better than with untreated blastocysts. The main result is therefore that a higher number of cells can be counted with greater exactitude.

Treatment in water (0 per cent sodium chloride) was only carried out with two blastocysts, as it immediately became clear that most of the metaphases pass on to ana- or telo phase. By treating the blastocysts in common physiological saline solution only one cell per blastocyst, approximately, could be used. The best results are obtained by using a 0·45 per cent saline solution, but next to this comes the 0·67 per cent despite the lower number of cells per blastocyst. It is more difficult to handle the blastocysts which have been treated in a 0·30 per cent solution as the tissue becomes too soft. In all the treatments the time was kept constant at 20 min., the age of the blastocysts was five days after mating, the fixative was alcohol–acetic acid (3 : 1) and the staining was done according to the Feulgen method, with 6 min. hydrolysis at 60°.

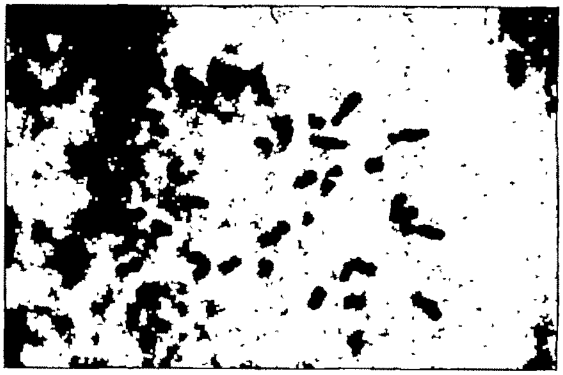

Fig. 1. Metaphase plate from a blastocyst treated in 0·45 per cent saline solution for 20 min. at 37° ($2n = 44$)

It should be mentioned that about 95 per cent of the cells have a chromosome number of $2n = 44$, which is the normal diploid number of the rabbit. However, a few cells have been found to be haploid, while others must be classified as polyploid cells with $3n$ or $4n$ chromosomes. Details of these chromosome numbers will be published elsewhere, when the experiments have been finished.

I am indebted to Mr. P. J. Åstrom for his help throughout the experiment.

Breeding Season of the Wild Rabbit in New Zealand

Little reliable information is available on the breeding cycle of the wild rabbit (*Oryctolagus cuniculus*) in New Zealand, though there is a widely held popular belief, quoted by Marshall[1], that in certain localities the animal breeds throughout the year. An investigation of the reproduction of the wild rabbit has been carried out on the Gwavas Forest area, thirty miles south-west of Napier in the Hawkes Bay Province of the North Island of New Zealand over the period March 1950–February 1952. During this time, 1,766 adult females were examined: a female having a paunched weight of more than 700 gm. was taken as adult, this being the lightest weight of any pregnant animal found.

The percentage of adult females pregnant in each period of four weeks over the two years is shown in the top half of Fig. 1. Some pregnant females can be found at any time of year; but there is, nevertheless, a well-defined breeding season, starting in mid-winter (June) and lasting four or five months, when

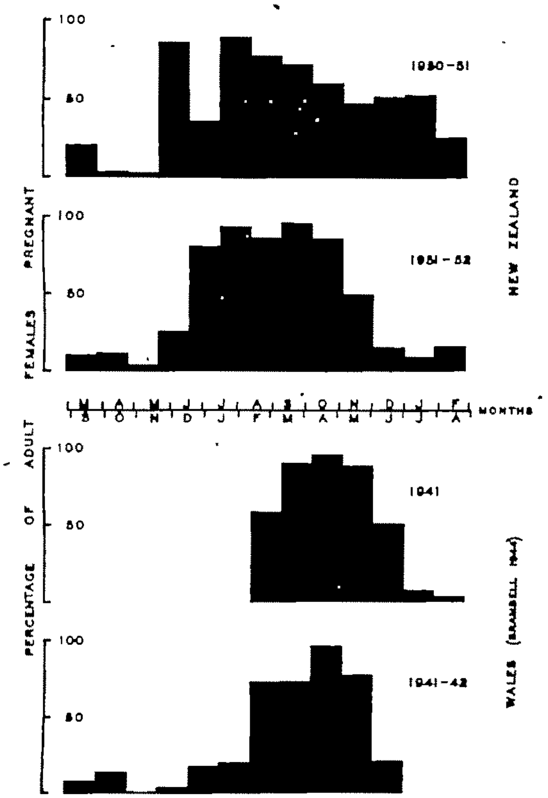

Fig 1

reproductive activity is very high; but from February to May little breeding occurs. There were a number of quite marked differences between the two years; in 1950 the rabbits started breeding about a month earlier than in the following year, and the end of the breeding season was more drawn out, more than 50 per cent of the adult females being pregnant throughout December and January. It was suspected that many of the females breeding at this time had themselves been born earlier in the season; but the method that was later developed[2] for distinguishing fully grown animals of up to nine and a half months old from older ones had not then been worked out. In the following year most of the rabbits that were breeding at this time were less than nine months old; thus it is possible that the duration of the breeding season may be largely determined by the survival-rate in the early litters. The reduction in male fertility which brought to an end the breeding season in Wales[3] was not so apparent in Hawkes Bay.

Brambell[3] carried out a detailed investigation of the reproduction of the rabbit at Bangor in North Wales: in the lower half of Fig. 1 his figures have been grouped in four-weekly periods that correspond seasonally with the New Zealand ones, so that the variations in pregnancy-rate throughout the year can be directly compared. It is apparent that in Hawkes Bay the period of high breeding activity lasts longer than in Wales: and the most striking difference is in the time of onset, which occurs eight to ten weeks earlier. Other European mammals, particularly ruminants and ferrets, introduced into the southern hemisphere, adhere very closely to the corresponding breeding season[4].

In many spring-breeding animals the increasing length of daylight is supposed to be the proximate factor responsible for the start of the breeding season. This cannot be so for the rabbit, since in Hawkes Bay the breeding season starts on or before the winter solstice. Hart[5] has suggested that it is the ratio of light to dark rather than increasing planes of light that is important in stimulating the onset of œstrus; it is therefore interesting that the length of day at Gwavas (lat. 40° S.) in June, and at Bangor, North Wales (lat. 52° N.) in February is approximately the same—between nine and ten hours; though this may be purely coincidental, as the rabbit also breeds in lower latitudes where the day-length is always longer than this. It is, however, likely that other factors such as the level of nutrition may also play an important part, though this could not be assessed in the present case. Baker[6] found that the onset of the breeding season in related species of birds in temperate regions tended to be twenty to thirty days earlier for each ten degrees of latitude towards the equator; similarly with sheep[7], the breeding season tends to start earlier and last longer in lower latitudes. It is therefore possible that the rabbit may be found to have a similar pattern.

A detailed account of this investigation on the reproduction of the rabbit in New Zealand is being prepared for publication.

Environmental Control of Coat Changes in Cattle

CATTLE of European origin usually possess a long, woolly coat of hair in the winter; in spring the long hairs are shed and by summer the coat is smooth and sleek. These seasonal changes occur with great regularity, and as they are an aid to the animal in preserving thermoneutrality, it is commonly supposed that they are regulated by environmental temperature.

However, regulation through a photoperiodic mechanism is suggested by the fact that coat changes in the mink[1], fox[2], and horse[3] are now known to be influenced by light. Further, Laing[4], using increased light during winter in England to stimulate œstrus in cattle, noted a tendency for shedding of the hair to occur.

In the absence of definite knowledge on the matter, an experiment was designed and is now in progress at the Physiology Department, University of Queensland, to test the possible importance of light in regulating seasonal coat changes in cattle.

Eight Poll Shorthorn calves, aged two weeks to two months, were divided into two similar groups, control and experimental, of four animals each. After a six-week period of conditioning to their surroundings and feed, the experiment, involving for the experimental group complete reversal of the seasonal trend of daylight hours, commenced on February 2, 1954.

Each group occupied a separate stall but was similarly treated except for the daily quota of light provided. The control stall was open to natural daylight and, as no other light was allowed, the calves in it received the daily duration of light normal for the latitude of Brisbane. This amounted to just over 14 hr. of light a day at the start, the level decreasing gradually with the approach of winter to just over 11 hr. at the time of writing (June 7). The experimental stall was also open to daylight, but in it day-length could be either shortened, using black-out arrangements, or increased by switching on four 250-watt electric lights in the evening and early morning. Using these facilities, the experimental calves were started in the experiment at a daily light-level of a little more than 10 hr. This was raised gradually, changes being made weekly, to the present level of 16½ hr. Thus the experimental calves were placed on an increasing plane of light while the controls received decreasing light.

Temperature differences in the two stalls have at no time exceeded 3° F. All eight calves have increased in weight at a similar satisfactory rate.

Monthly hair samples have been taken from separate standard areas of skin on the flank for use in the quantitative assessment of any changes. Photographic records have also been made.

The first effect of the experimental treatment became apparent on May 5, three months after the start of the experiment, when, during the hair sampling, it was noticed that swathes of long hair could be rubbed off the neck and shoulders of the experimental calves. This process of shedding has continued in all four calves of the experimental group. Their heads and necks are now smooth and glossy, and the shedding is extending posteriorly.

The hair of the control calves, on the other hand, is firmly attached and the coats of these animals have become long and woolly, typical of the appearance to be expected with the approach of winter. These visible changes are reflected quantitatively by the monthly hair sampling results (see Fig. 1).

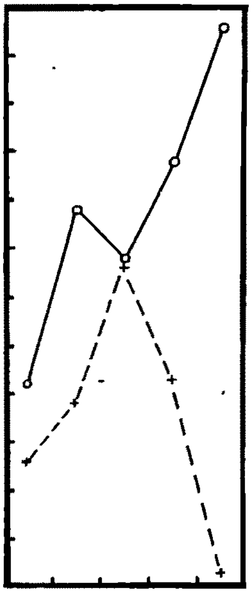

Fig. 1. Group average weights of hair samples, plotted for each month. —O—, control; – – – + – – –, light treated

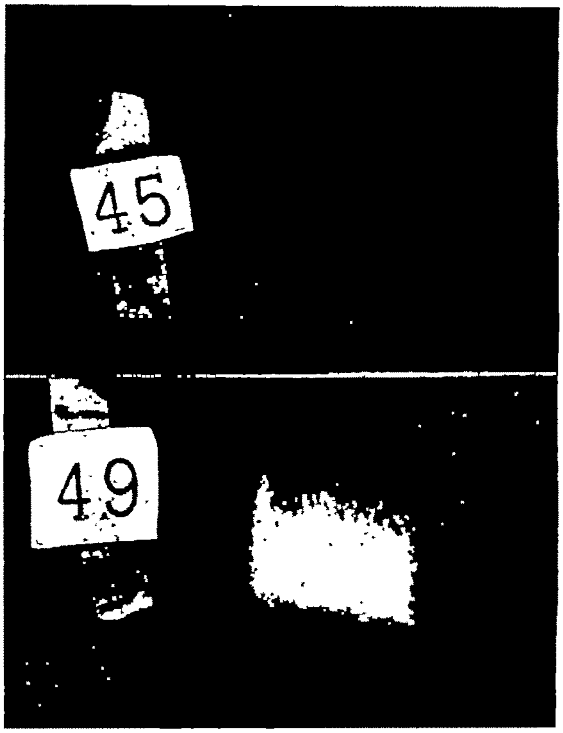

Fig. 2. Regrowth of hair on square patches of skin which had been clipped bare 20 days previously is greater on control (45) than on experimental calf (49). Photographs taken on May 25, 1954

Another point now noticeable is that on the areas of skin from which recent monthly hair samples have been clipped, the experimental calves have grown less hair than the controls (see Fig. 2).

From the results so far available, it is clear that the light environment exercises an important influence on the seasonal coat changes of cattle. A rising plane of light initiates shedding of long hairs and, with cattle of the type used in this experiment, shedding commences after approximately twelve weeks of increasing light. Growth of new hair also appears to be less on a rising plane of light than it is in decreasing light.

This experiment forms part of an inquiry into adaptation of cattle to tropical environments being undertaken co-operatively by the Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, and the Department of Physiology, University of Queensland. Thanks are due to Prof. W. V. Macfarlane for advice and encouragement.

Production of Worm-free Lambs at Pasture

RECENT research has shown that a considerable loss of productivity occurs in sheep carrying a sub-clinical infestation of nematodes parasitic in the alimentary tract[1,2]. This work has depended upon comparisons of worm-free and lightly infected groups of animals and has therefore been carried out in indoor pens. It has been concluded that infected sheep gain weight at less than their optimum rate; but it is not clear how valid these results are for sheep at pasture, under normal conditions of continual reinfection by grazing. In order to measure the actual loss due to sub-clinical parasitism it is necessary to compare normally infected sheep with similar, worm-free animals under grazing conditions. An investigation was therefore carried out during March–July 1954 at the Grassland Research Station, Stratford-on-Avon, into the possibility of raising worm-free lambs at pasture.

As previously indicated[3], two essential requirements are (*a*) a worm-free pasture and (*b*) a grazing management capable of preventing infection of the lambs from their infected ewes.

The pasture used was a newly sown ley following two successive corn crops. The land had not been grazed by either sheep or cattle for two years. The grazing management adopted was based on the fact that the majority of the nematode eggs passed in the fæces of the host do not reach an infective larval stage for at least three days.

Nine ewes and fifteen lambs were transferred to the pasture when the lambs were less than twenty-four hours old and folded over it, using movable fences. The animals were moved in such a way that they never remained on the same area for more than two days and were never pastured on a previously grazed area. Regular fæcal egg-counts were carried out on both the ewes and lambs, 5–10 gm. samples being taken. The average egg-count for the ewes during this period was 300 eggs per gm. No anthelmintic was administered to either ewes or lambs during the time these were in the experiment.

The lambs were weaned at fifteen weeks and their egg-counts at this time were as follows: No eggs of *Nematodirus* spp. were found at any time; two lambs had counts of 2 and 1 *Trichuris ovis* eggs per gm., respectively; five lambs had negative counts for *Strongyloides papillosus*, and of the remainder 12 eggs per gm. was the highest count; the counts for 'other strongyles' were negative for twelve lambs and 1, 3 and 27 eggs per gm. respectively for the remaining three animals.

During the first thirteen weeks only an occasional *T. ovis* egg and low counts for *S. papillosus* were recorded. One lamb appeared to acquire a slight infection shortly before weaning. The complete absence of 'other strongyle' eggs in twelve of the lambs shows that it is possible to raise 'worm-free' lambs in the field. The negligible counts for other species compare favourably with 'worm-free' lambs raised in indoor pens. For comparison, an equivalent group of ewes and lambs were grazed on the re-growth of pasture following the first group and managed in a similar manner on such infected pasture.

It may be noted that at weaning time the average egg-count (excluding *S. papillosus*) of these lambs was 90 eggs per gm. Their peak of 400 eggs per gm. was reached in June, at which time they were dosed with phenothiazine. The worm-free lambs gained weight more rapidly than the sub-clinically infected animals.

The experiment has confirmed that a ley sown on land ungrazed for two years is worm-free. The possibility of retaining 'worm-free' ewe lambs and maintaining them as a 'worm-free' breeding unit, and the effect of age on the development of resistance to infection, are under investigation.

Normal Hæmatological Values in the Buffalo

IN view of the wide range in the characteristics of the blood constituents of various animals, an investigation has been carried out to determine the normal values for various blood constituents of the domestic buffalo (*Bos* (*Bubalus*) *bubalis*).

Twenty adult Egyptian buffalo-cows were available at the Animal Breeding Research Farm, Giza, Egypt. They ranged in age from three to ten years and were healthy and non-pregnant. Samples of oxalated blood were taken during the period, January–April 1953. Red, white and differential counts were carried out and the diameter of the corpuscles was determined in dry stained smears. The following determinations were made: sedimentation-rate (using Westergren method), clotting time (Sabraz's capillary tubes), hæmoglobin content (Halden hæmoglobinometer), specific gravity (Weiss copper sulphate method), *p*H (Beckman *p*H meter) and the hæmatocrit (using the Winthrop technique). The following chemical constituents were also determined: blood sugar (Folin and Wu method), plasma proteins and non-protein nitrogen fraction using a semi-micro Kjeldahl method (Van Slyke technique), sodium (Weinback's method), calcium (Roe and Kohn technique) and phosphorus (Fisk and Subba Row's method).

The erythrocyte count was $6 \cdot 8 \times 10^6/\text{mm.}^3$, while the leucocyte count was $6 \cdot 7 \times 10^3/\text{mm.}^3$. In a differential leucocytic count, the percentages of lymphocytes, neutrophils, monocytes, eosinophils and basophils were 51, 36, 8, 5 and less than 1 respectively. The average diameter of erythrocytes was 5·5 μ, while the diameters of lymphocytes, neutrophils, monocytes, eosinophils and basophils were 6·8, 11·3, 15·7, 11·8 and 11·8 μ respectively.

The physiological and chemical characteristics of buffalo blood are shown in Table 1.

In the buffalo, the erythrocyte count is higher than in cattle and lower than in sheep and horse, whereas the leucocyte count is less than in cattle, horse and sheep. The percentage of lymphocytes, monocytes and eosinophils (in the differential count) in the buffalo is higher than in sheep and horse and lower than in cattle. The percentage of neutrophils in the buffalo is less than in sheep and horse and higher than in cattle. The basophils have almost the same frequency (less than 1 per cent) in all farm animals. The sedimentation-rate in the buffalo is higher than in cattle and lower than in horse, while the hæmoglobin content is higher in the buffalo than in all other farm animals. The clotting time of buffalo blood is longer than in sheep, shorter than in horse and similar to that of cattle. In general, buffalo blood is characterized by a relatively (to other farm animals) high

Table 1. PHYSIOLOGICAL AND CHEMICAL VALUES OF BUFFALO BLOOD

Items	Unit	Range	Mean ± S.D.	C.V. %
Specific gravity	gm./ml.	1·05–1·07	1·058 ± 0·012	1
pH		7·35–7·6	7·45 ± 0·0382	0·5
Sedimentation-rate	mm./1 hr.	2–8	6·0 ± 1·65	29
Clotting time	min.	6–7·25	6·75 ± 0·065	1
Hæmoglobin	gm./100 ml.	11·04–15·18	12·98 ± 1·236	10
Hæmatocrit	percentage	38–52%	44·3 ± 3·028	7
Sugar	mgm./100 ml.	72–90	81·4 ± 3·411	4
Plasma proteins	gm./100 ml.	6·62–7·62	7·42 ± 0·266	4
Plasma non-protein nitrogen	mgm./100 ml.	25–42	36 ± 3·142	8
Plasma sodium	mgm./100 ml.	400–430	415 ± 6·53	2
Plasma calcium	mgm./100 ml.	9–11	10 ± 0·156	2
Plasma phosphorus	mgm./100 ml.	26–31	28 ± 1·032	3

content of sugar plasma proteins and phosphorus and low content of calcium and sodium.

The blood picture of the animal is a result of an interaction between environmental (mainly domestication) and hereditary factors. The blood picture of the Egyptian buffalo falls among that of the Kumeoni, Hariana and Dhanni breeds of the Indian buffalo reported by Kehar and Murty[1]. A comparative study of normal hæmatological values is of great significance in studying the origin and evolutionary trends of species and breeds; such studies are also of particular interest for practical animal husbandry in the tropics, since certain features may be correlated with heat tolerance, environmental stress and disease immunity.

Thanks are due to Prof. A. L. Badreldin, chairman of the Animal Breeding Department, Faculty of Agriculture, and to Dr. M. H. Maghraby, of the Ministry of Agriculture, for providing facilities and help.

In vitro Production of Tropical Black Earth

THE term 'grumusol' was proposed by Oaks and Thorp[1] for the dark-coloured clays which occur in many tropical and sub-tropical regions. Much is known concerning the chemistry[2,3], mineralogy[4] and fertility[5] of a number of these soils; but, as pointed out by Joffe[6], "the source of the black colour has been a kind of an enigma".

During the course of an investigation into the origin of the colour of Gold Coast black Akuse clay, the following experimental approach was adopted. Experimental pedology (the production of characteristic soil types under controlled laboratory conditions) is still a neglected section of soil science, and apart from the *in vitro* production of podsols[7] there has been scarcely any published work on this approach. The success met with here has prompted us to publish the results obtained, in order to indicate the potentialities of the method for studying tropical soil formation.

The three substrates used were kaolin (white), Bunso clay (yellow-red), and Akuse clay from which the organic matter had been removed by heating to 600° C. (yellowish-brown). 40-gm. samples of each of these substrates were placed in a series of 12-oz. bottles. These were then amended so that all possible combinations of five variable factors were represented.

The factors were: (1) Presence of readily-decomposable organic matter: (*a*) 3 per cent finely ground *Vetiveria* grass (dominant species on Akuse clay); (*b*) no plant material added. (2) Presence of an inoculum of black Akuse clay: (*a*) 1 ml. of a 1 : 5 soil suspension added; (*b*) no inoculum added. (3) *p*H: (*a*) adjusted to *p*H 5 with 2 *N* hydrochloric acid; (*b*) adjusted to *p*H 8 with 0·25 *N* sodium hydroxide. (4) Presence of excess calcium carbonate: (*a*) 5 per cent calcium carbonate added; (*b*) no calcium carbonate added. (5) Water content: (*a*) substrate kept permanently waterlogged; (*b*) substrate saturated with water and then left to dry out; alternation of anaerobic and aerobic conditions repeated throughout the course of the experiment.

The bottles were kept at room temperature (22–35° C.) and the results recorded after six weeks. No colour changes occurred in the amended kaolin; but in both the red Bunso clay and the mineralized Akuse clay there developed under certain conditions the characteristic grey colour associated with 'grumusols'.

There were four essential conditions for the development of this colour in the mineralized Akuse; namely, the presence of plant material, a soil inoculum, alkaline reaction and waterlogging. The addition of calcium carbonate, however, had no effect.

For the colour to develop in red Bunso clay, alkaline waterlogged conditions and the presence of plant material were again essential. An inoculum of Akuse clay was unnecessary, indicating that the native microflora of the ferruginous clay is able to induce the colour change if the soil conditions are favourable. In the absence of added calcium, the grey zone in Bunso clay was small and ill-defined, indicating that calcium was involved in the production of the colour and that the lack of a response to added calcium carbonate in mineralized Akuse was due to the high calcium status already existing in the soil.

Grumusols develop in warm regions with well-defined wet and dry seasons[1]. Our results indicate that the dark colour of these soils is due to the activity of anaerobic bacteria which develop in the alkaline, poorly drained montmorillonitic clays during the wet season. This confirms the hydrogenic origin of tropical black clays, as suggested by the work of Mohr[8] and del Villar[9].

Pile Irradiation of Polyethylene Terephthalate ('Terylene')

In view of its bearing on the recent communication from Miss Little[1], some simultaneous and independent work, initiated by Charlesby's claim to have cross-linked polyethylene terephthalate by pile irradiation[2], is perhaps worth recording.

The solution viscosities of two ethylene terephthalate polymers, both before and after varying amounts of irradiation in the BEPO pile at the Atomic Energy Research Establishment, Harwell, were measured in *o*-chlorophenol at 25° C. One polymer ('microdull') contained titanium dioxide as a delustring agent but there was none in the other ('bright'). For both polymers, the limiting viscosity number $[\eta]$ fell and the Huggins's viscosity slope constant[3],

$$k^1_H = \frac{d\left(\frac{\eta - \eta_0}{\eta_0 c}\right)}{dc} \Big/ [\eta]^2,$$

where η and η_0 are the viscosities of solution and solvent respectively and c is the concentration of the solution in gm./ml., rose with increase of radiation dose. It should perhaps be noted that hydrolysis will contribute to the $[\eta]$ drop for the samples of bright polymer irradiated longest in sealed tubes if the temperature in the pile approaches 100° C.

Polymer	Radiation energy (MW. hr. × 10^{2})	$[\eta]$	k^1_H
Microdull	0	76	0·25
,,	0·3 in air	65	0·39
,,	0·5 ,,	62	0·41
,,	1·0 ,,	57	0·43
,,	2·0 ,,	52	0·38
Bright	0	65	0·27
,,	2 *in vacuo*	49	0·43
,,	4 ,,	42	0·58
,,	8 ,,	37	0·52

Although the exact significance of k^1_H is not clear, it is generally agreed that it depends on the interactions between the molecules in high polymer solutions: a rise in k^1_H would correspond to a reduction in the effectiveness of *o*-chlorophenol as a solvent for the polymer. The exponent α, which is thought to be unity for spinning-grade polyethylene terephthalate (W. R. Throssell, unpublished work), in the relation between $[\eta]$ and number average molecular weight $\overline{M}_n$, $[\eta] = K\overline{M}_n^{\alpha}$, would also be expected to fall and cause a reduction in $[\eta]$ uncompensated by the accompanying rise in K. Hence, the observed drop in $[\eta]$ does not necessarily indicate a reduction in $\overline{M}_n$, although the magnitude of the effect suggests that this is probable.

The samples which had been more heavily irradiated *in vacuo* show a small but significant decrease in Vicat softening point of 0·27° C. for unit fall in $[\eta]$. This would be consistent with a modification of the chain structure, for example, by branching. It could be caused by occluded degradation products, but these would probably be removed during the crystallizing pretreatment for one hour at 140° C. before the softening-point test. It cannot be due merely to a reduction in molecular weight, for a fall in softening point is not detected in samples produced by hydrolysis of normal polyethylene terephthalate until $[\eta]$ falls below about 30.

In agreement with the conclusions from X-ray data[1], these results suggest that the effect of pile radiation, at least up to 800 MW. hr., on polyethylene terephthalate is degradative, although possibly accompanied by branching. Furthermore, the relative ease of solution, unchanged by irradiation, of all the samples in *o*-chlorophenol, together with the lowered softening point are inconsistent with the presence of any measure of cross-linking as reported by Charlesby[2].

A Corrected Guldberg Rule

According to the well-known rule of Guldberg[1], the normal boiling point of a liquid is two-thirds of the critical temperature on the absolute scale. The rule is not obeyed by liquids of low boiling point[2], and even for liquids boiling in the range 20–250° C. the ratio T_b/T_c varies from 0·58 to 0·70. Inasmuch as these deviations arise from the different cohesive forces, and the latter are related to the surface tension, we may write

$$T_b\gamma_b^n/T_c = k,$$

where γ_b is the surface tension of the liquid at the boiling point, and n and k are constants. For ordinary organic liquids the relation

$$T_b\gamma_b^{\frac{1}{4}}/T_c = 4/3 \qquad (1)$$

is generally more accurate than the simple Guldberg rule, as may be seen from the following data:

Substance	T_b/T_c	$T_b\gamma_b^{\frac{1}{4}}/T_c$
Carbon disulphide	0·586	1·338
Ethyl bromide	0·618	1·335
Benzene	0·629	1·348
1,1-Dichloroethane	0·633	1·348
Cyclohexane	0·640	1·316
Ethyl ether	0·658	1·305
n-Propyl formate	0·663	1·355
Methyl butyrate	0·677	1·349
*iso*Amyl formate	0·688	1·344
n-Butyl acetate	0·690	1·342
n-Octane	0·700	1·303

A relation between the parachor and the critical volume may be derived from (1). Since the molar volume of a liquid at the boiling point is three-eighths of the critical volume[3], we have

$$\frac{T_b\gamma_b^{\frac{1}{4}}V_b}{T_cV_c} = \frac{1}{2},$$

so that the parachor is given by

$$P = \frac{1}{2}\,\frac{V_cT_c}{T_b}. \qquad (2)$$

A study of the experimental data led Ferguson and Kennedy[4] to propose the empirical formula

$$P = 0{\cdot}324\, V_c^{\frac{7}{8}}T_c^{\frac{1}{4}},$$

but Lennard-Jones and Corner[5] were able to show, on the basis of dimensional considerations, that the parachor is proportional to $V_c^{5/6} T_c^{1/4}$. For non-associated organic compounds, including those in which the molecules are so unsymmetrical as to restrict rotation in the liquid state, they found that the formula

$$P = 0{\cdot}410\, V_c^{5/6} T_c^{1/4}$$

gave slightly better agreement than that of Ferguson and Kennedy. Examination of the available data for liquids of this type reveals that formula (2) is definitely superior to that of Ferguson and Kennedy, and is in general slightly more accurate than that of Lennard-Jones and Corner.

Paramagnetic Resonance, a New Property of Coal-like Materials

PARAMAGNETIC resonance, which has given interesting information on several structures[1], can be used for studying coal-like materials. Using a microwave spectrometer (9,000 Mc./s.) for electronic paramagnetic resonance, we have observed a characteristic line for coals[2]. This sharp line is associated with a Landé factor of 2, which is the free electron value. These results lead us to believe that this paramagnetism is linked with the structure of coal-like materials and cannot be attributed to the minerals always present, such as iron. In the present communication we give further details on the results observed for coals[2] and for several coal-like materials in which paramagnetic resonance has been detected.

The samples of coal studied, coming from mines in northern or eastern France, are of different geological ages. They correspond to the following French designations: anthracite, quart-gras, demi-gras, trois-quart-gras, flambant-gras, flambant-sec. The amplitude of the line decreases from the oldest coal (anthracite) to the youngest one (flambant-sec). Roughly, the amplitude gets smaller as the amount of carbon decreases in the samples and as the amount of volatile substances and oxygen increases. Charring modifies the phenomenon considerably. On heating the coals up to 500° C., the line is seen to decrease gradually with increasing temperature. The line disappears quickly on heating the same samples between 500° and 600° C., when graphitization and electrical conductivity appear. After coking is completed (1,000–1,100° C.) no line can be seen. It must be emphasized that several samples of graphite did not give any line with our apparatus, though a weak line has been reported by Castle[3]. With regard to lignites, the line is absent in a sample from Hostens, present but weak in a sample from Fuveau and in both instances it becomes very strong after heating at 300° C. These results have led us to make some experiments with such materials as charcoals, sugar charcoal and pitches.

Charcoal prepared from pine wood and coconut and also some lightly charred sugars (saccharose, glucose) give a fairly intense paramagnetic resonance line. This line disappears in charcoals activated at 900° C. in presence of combustion gases and steam. No line appears in crude oils; but one is found in pitches which are residues from crude oil distillation. It can be said that paramagnetic resonance appears when carbohydrates are damaged either by Nature, as in coals, or artificially by heating, as in charcoals, sugar charcoal and pitches. The same line appears if the samples (woods, sugars) are irradiated by γ-rays, as was found by two of us[4], which suggests the same sort of damage. This paramagnetic resonance cannot be attributed to a specific defined structure at present; but further experimental and theoretical work is being carried out.

Electroretinal Photopic Sensitivity Curves

SINCE Adrian[1] first suggested the existence of separate rod- and cone-components in the human electroretinogram, there have been attempts to isolate them so as to demonstrate the degree to which their spectral sensitivity curves adhered to scotopic or photopic patterns.

Thus Riggs, Berry and Wayner[2] determined the function for the *B*-wave. With a 7·5° foveally centred stimulus-flash, the curve closely resembled the scotopic function but was displaced toward the blue. Armington, Johnson and Riggs[3] derived a similar curve for the *A*-wave of the dark-adapted eye. Again excess blue-sensitivity appeared. Boynton[4] has supposed this to be related to the part played by stray light. With small stimulus areas a significant portion of the electrical response is due to light scattered over the peripheral retina, outside the focal area. One contributor is Rayleigh scatter, varying as an inverse function of the fourth power of the wave-length, scattering blue more than red. To support this interpretation, Boynton shows that divergence from scotopic values is less when larger areas are used. Johnson and Armington[5] have confirmed this, demonstrating that with full-retinal stimulation, using an integrating sphere, electrical sensitivity curves for the *B*-wave of the dark-adapted eye coincide with the usual scotopic luminosity curve.

Armington[6] has fitted data for the *X*-wave (Motokawa's designation for Adrian's photopic component) to the CIE photopic luminosity curve. With the photopic receptors we would expect stray light to have less effect. Cones are concentrated near the fovea and are supposed (cf. Stiles–Crawford effect[7]) to be directional. It is disconcerting to find that the *X*-wave curve diverges from the photopic curve just as the small-area *B*-wave curve diverges from the scotopic function. No one has used full-retinal stimulation to elicit the *X*-wave. We cannot say whether such a procedure would bring the *X*-wave

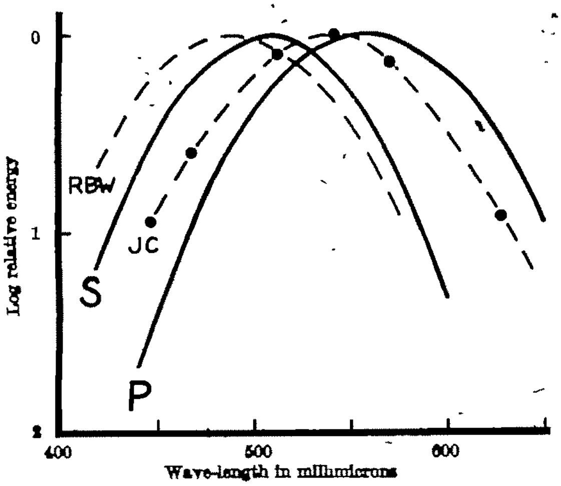

Fig. 1. Log relative energy at each wave-length to achieve standard response. Maxima of curves adjusted to equality. *S*, Scotopic visibility curve; *RBW*, curve for *B*-wave (ref. 2); *P*, photopic luminosity curve; *JC*, curve for *X*-wave obtained by authors using four per sec. flashes in light-adapted eye. Points indicate photopic peaks of narrow-band filters used. Data of three determinations averaged

results into line. Armington speculates that it might not. He has used night-blind subjects and found some alleviation of the disparity. This suggests that the *X*-wave of the normal-seeing person, as elicited by Armington's procedures, is partly of scotopic origin or, alternatively, that the peripheral cones of his night-blind subjects had been affected so that the effect of stray light was diminished even though a 'pure cone' index was being observed.

To throw additional light on the problem we have employed a technique suggested by Dodt[8], in a communication in *Nature* in 1951. He affirms, and we agree, that with a stimulus flickering above a rate of about 20 per sec., scotopic responses appear to fuse, manifesting the equilibrium characteristic of steady illumination. Responses synchronous with 30 per sec. flashes should represent activity of the faster responding photopic system. In the dark-adapted eye there is an initial *B*-wave, following which the 30 per sec. fluctuations appear. These may continue, unaltered, for several minutes. Records taken after different lengths of time in darkness differ only in the size of the initial *B*-wave.

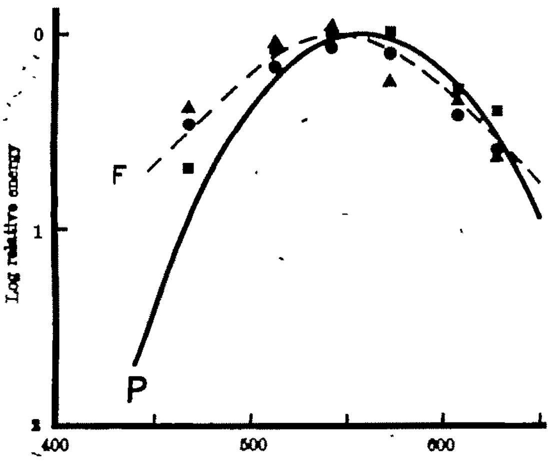

Fig. 2. Log relative energy at each wave-length to achieve standard response. *P*, Photopic luminosity curve; *F*, curve for 30 per sec. flashes. Triangles represent one set of determinations on subject A.T., squares and circles two sets for subject P.J.

Using 4 per sec. flashes (to which the above argument does not apply), and delivering these to the light-adapted eye, we confirmed Armington's findings for the normal eye. Total height of response was measured, from trough of *A* to peak of *X*. Fig. 1 shows the form of the curve obtained using a 20-µV. response criterion. Excess blue-sensitivity is apparent. (Apparatus and treatment of results in this work were similar to those employed in refs. 2–6.)

With 10-m.sec. flashes delivered to the dark-adapted eye at a rate of 30 per sec., and using a 10-µV. trough-to-peak response criterion, the 'sensitivity curve' (Fig. 2) resembles the photopic more than the scotopic function, but is still displaced slightly toward the blue and is less sharply peaked. We must either consider the hypothesis that Rayleigh scatter contributes to the photopic electroretinogram, as it does to the scotopic, or we must admit that neither the employment of night-blind subjects nor the use of flickering stimuli prevents intrusion of a blue-sensitive system, presumably the scotopic, which contributes to the electroretinogram yet fails to show itself during determination of the photopic luminosity curve by the standard procedures.

This work was supported by a contract between the U.S. Office of Naval Research and Brown University, and carried out in the Psychology Laboratories of Brown University.

A Disease Epidemic in Fish

AN epidemic has occurred in a fish culture of *Tilapia mossambica* in Southern Rhodesia during June 1954. The disease had a mortality of more than 90 per cent of the exposed population. *Barbus* species were also affected. Fungus was seen mostly on the extremity of the dorsal fin but frequently occurred on the caudal peduncle, the tail and on the inter-orbital region. Affected fish were seen lying in shallow water and gasping at the surface. The intestine was filled with a clear gelatinous fluid. No macroscopic gill lesions were noticed. Although cold (below 56° F.) seems a predisposing factor, the etiology is not clear. Helminth cercaria may be implicated as well as fungus. Histologically gill necrosis associated with an invasion of conidia-like bodies, and kidney and liver cloudy swellings are present.

Further details will be published later.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Wednesday, September 29

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Dr. A. H. Cutler: "Computing Circuits in Flight Simulators".

Friday, October 1

Hospital Physicists' Association (in the Reid-Knox Hall, British Institute of Radiology, 32 Welbeck Street, London, W.1), at 8 p.m.—Prof. C. A. Coulson, F.R.S.: "Douglas Lea—Physicist into Biologist" (Fourth Douglas Lea Memorial Lecture).*

Saturday, October 2

Royal Photographic Society of Great Britain—Scientific and Technical Group, in conjunction with the University of Durham (in the Lecture Theatre, Stephenson Building, King's College, Newcastle-upon-Tyne), at 10 a.m.—Conference on "Scientific and Technical Applications of Photography".

Association of Clinical Biochemists (joint meeting with the Association of Clinical Pathologists, at the Grand Hotel, Brighton)—Meeting on "Thyroid Function". Morning Session—Papers on "Chemical Pathology"; Afternoon Session—Papers on "Thyroid Function".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Junior Research Fellow (with one or two years postgraduate experience) in Biochemistry, to undertake research in the formation of complexes between metal ions and polypeptides and proteins—The Secretary, The University, Aberdeen (October 1).

Assistant Physicist (with an honours degree in physics and preferably with hospital experience)—House Governor, The London Hospital, Whitechapel, London, E.1 (October 2).

Senior Lecturer or Lecturer (with teaching and research or industrial experience in electronics) in Physics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (October 4).

Analytical Chemist (with first- or second-class honours degree and preferably with experience in the rubber industry), to supervise analytical work in the chemical division and to carry out research on new methods of physical and chemical analyses in connexion with the natural rubber producing industry; Chemical Engineer (with first- or second-class honours degree and a professional qualification in chemical engineering), to carry out development work to the pilot plant stage, at the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (October 8).

Scientist (with good honours degree in chemistry or physics, preferably with specialization in physical chemistry and experience of surface chemistry), at the Coal Survey Laboratory, Leeds—National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/841 (October 9).

Lecturer, Grade A, in Botany, and a Lecturer, Grade A or B, in General Science, at the Kumasi College of Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (October 11)

Keeper (with experience in archives administration) in the Department of Archives—The Director, Museums and Art Gallery, New Walk, Leicester (October 12).

Lecturer (graduate in electrical engineering and preferably with experience in electrical measurements, transmission and distribution of electricity, or high frequency line communication) in Electrical Engineering, at the Auckland University College—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 15).

Lecturer in Machine Tools and Metrology in the Department of Engineering Production, to be responsible for the Metrology and Machine Tool Research Laboratories and for postgraduate teaching and research—The Secretary, The University, Birmingham 15 (October 15).

Research Officer (graduate, preferably with honours degree in veterinary or agricultural science with specialization in animal genetics, and with experience in wool technology and statistical methods and knowledge of the sheep and wool industry) in the Trangie Experiment Station, New South Wales Department of Agriculture, to be responsible to the Director of Veterinary Research for organizing and supervising research projects of the Wool Research Laboratory—The Agent General for New South Wales, 56/57 Strand, London, W.C.2 (October 18).

Senior Lecturer (preferably with good knowledge of classical theoretical physics and quantum theory) in Physics, at the University of New England, Armidale, New South Wales—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 18)

Senior Lecturer in Agricultural Economy; Lecturer in Soil Science; Lecturer in Animal Production at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 22).

Chair of Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (October 25).

Lecturer in Agricultural Economics and Farm Management at University College, Ibadan—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 25).

Senior Lecturer in Statistics at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 29).

Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar, The University, Manchester 13 (October 30).

Senior Horticulturist, Senior Scientific Officer grade (with honours degree in botany and with research experience) in the Pomology Section, for work on fruit tree rootstocks—The Secretary, East Malling Research Station, Maidstone, Kent (October 30).

Chair of Applied Mathematics at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 31).

Chair of Animal Husbandry at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 6).

Electronic Engineer or Physicist to assist in installation and operation of electronic digital calculator—The Secretary, Birkbeck College, Malet Street, London, W.C.1.

Lecturer (with a degree in mechanical engineering and teaching experience, and preferably with industrial experience) in the Department of Engineering—The Principal, County Technical College, Gainsborough.

Lecturer (with an honours degree and preferably with industrial experience) in Physics—The Principal, Paisley Technical College, Paisley.

Principal or Senior Scientific Officer (with first- or second-class honours degree in civil engineering, or equivalent qualification, with experience in the planning and construction of roads or similar civil engineering work, and preferably with experience of economic problems) at the Road Research Laboratory, Harmondsworth, to study the economics of road construction and maintenance—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting E591/54/A.

Research Demonstrator in Physics—The Registrar, University College, Leicester.

Research Engineer (with a university degree and some workshop experience, and preferably with training in research), for experimenta work into the stresses in steam pipe-work with particular referenc to advanced steam conditions—Prof. H. Ford, Mechanical Engineering Department, Imperial College, London, S.W.7.

Rubber Technologists or Science Graduates (interested in th practical applications of science) to undertake technological investigations—The Secretary, Research Association of British Rubbe Manufacturers, Shawbury, Shrewsbury, Salop.

Senior Materials Engineer (with university degree in science and qualified for membership of the Institution of Civil Engineers and with at least 10 years postgraduate experience on road or airport construction including theoretical and practical experience of applied soil mechanics and analysis) in the Public Works Department, Gold Coast Government, to be responsible for the Materials Section, Public Works Department Road and Bridges Branch, including all its field and laboratory activities—Adviser on Recruitment, Gold Coast Office, Melbourne House, Aldwych, London, W.C.2.

Senior Scientific Officer (with first- or second-class honou degree in physics or physical chemistry, or equivalent qualifications and with several years postgraduate research experience) to lead a group investigating the application of engineering technology to th manufacture of explosive weapons, including the study of dust explosion and static hazards—The Senior Recruitment Officer, Atomi Weapons Research Establishment, Aldermaston, Berkshire, quoting 107/WGR/34.

Senior Scientific Officer (Ref. 659) (with first- or second-class honours degree in chemistry, or equivalent qualification, and with a least three years postgraduate experience of inorganic analysis) t take charge of group engaged on research and development work i inorganic analytical chemistry, including the application of moder analytical techniques; Senior Experimental Officers (Ref. 660 (with H.S.C. Science and experience in analytical chemistry) to supervise laboratories engaged on analyses of materials used in atomi energy processes; Assistant Experimental Officers (Ref. 661 (with H.S.C. Science and experience of chemical analysis, preferabl in the organic field) for analytical work on materials used in atomi energy processes, with the United Kingdom Atomic Energy Authority Capenhurst—United Kingdom Atomic Energy Authority, Industria Group Headquarters, P.O. Box 19, Risley, Warrington, quotin appropriate reference.

THE ADVISORY COUNCIL ON SCIENTIFIC POLICY

THE Advisory Council on Scientific Policy was established in 1947 "to advise the Lord President of the Council in the exercise of his responsibilities for the formulation and execution of Government scientific policy". It is concerned accordingly not with administration but with the strategy of scientific affairs, and in its seventh annual report*, breaking with the practice of the two previous reports, the Advisory Council reviews its activities, including those of the current year, during the whole period since it was established, in the light of post-war developments. The Council was established in the recognition that to-day a country's wealth and power are largely determined by the extent of its scientific knowledge and by its capacity to use that knowledge. It was also realized that the scientific institutions of Britain had grown up piecemeal, and that, although much of their cost fell on the Exchequer, no single body was concerned with the oversight of Government scientific policy in general, with the interaction of new scientific developments—desirable in the national interests—among themselves and with the functions of existing institutions; nor with the responsibility of advising whether the supply of scientific man-power was adequate to meet the needs both of Government and industry.

The first, and major, part of the present report is concerned with the scale of the civil scientific research effort, and discusses the expansion of scientific education and the demand for scientists, including the shortage of science teachers, and next the scale of Government-financed research. The fruition of policy, however, depends on the extent to which industrialists and farmers make use of advances in scientific knowledge, and on the extent to which scientific considerations are taken into account at the highest levels where policy is determined, in industry as well as in Government. The second part of the report, accordingly, reviews briefly the exploitation of the civil scientific effort both by Government Departments themselves and in industry.

The increase in the size of the universities of Britain, and, more particularly, the increase in the numbers of graduates in science and engineering, are, in the opinion of the Advisory Council, among the most noteworthy changes which have occurred in Great Britain during the past ten years. In 1952–53, the universities awarded 5,710 first degrees and diplomas in scientific subjects compared with 3,060 (including higher degrees) in 1938–39; for applied science the corresponding figures are 3,636 and 1,808, respectively; for medicine and dentistry, 2,369 and 1,792; and for agriculture, 803 and 246. Nor was 1952–53 the peak year for all subjects; only in chemistry were more honours degrees awarded in 1952–53 than in 1951–52. For pass-degrees and diplomas in pure science the peak was reached in 1950–51; in applied science it was earlier still—1949–50—and has declined steadily since. Honours degrees in chemical technology have declined from 121 in 1950–51 to 100 in 1952–53, although in engineering sciences as a whole they have remained fairly steady (1,025 in 1950–51, 998 in 1952–53).

---

* Seventh Annual Report of the Advisory Council on Scientific Policy, 1953–1954. Pp. iv+23. (Cmd. 9260.) (London: H.M. Stationery Office, 1954.) 1s net.

Discussing these figures in the light of the estimates of the Barlow Committee in 1946, the Advisory Council points out that, while over-cautious about the possibilities of increasing the output of trained scientists, the Barlow Committee was correct in predicting a continuing shortage, and that the position would become serious if the level of new investment in manufacturing industry increased and if the more backward sections of British industry began to employ trained scientists and engineers, not only in laboratories and workshops, but also in boardrooms and sales organizations. There is no indication, however, that the Advisory Council has attempted to estimate the future demand for trained scientists. Apart from discussions initiated by its Committee on Biology and Allied Sciences, the Advisory Council appears to have rested content with the survey made two years ago by its Scientific Man-power Committee, and to have made no further effort to obtain more accurate estimates from the various sub-committees of Lord Hankey's Technical Personnel Committee.

The Council is clearly concerned, however, as to the situation which might arise if investment increased materially, and if the demand for trained scientific man-power reached the proportions which might be regarded as adequate for a progressive industrial nation. There is evidence that the decline in the number of admissions to the universities since 1949–50 has been halted, although university departments in pure and applied science are now doing no more than maintain their student numbers. Numerically, the position of the technical colleges is more encouraging; the awards of National and Higher National Certificates are now about three and six times the pre-war figures, respectively.

Although about twice as many young men and women in each age-group are now going to the universities as compared with pre-war years, the ratio to-day (1 : 31 in each age-group) is still significantly less than in countries like Switzerland or the United States. The Advisory Council has no doubt as to the ability of the universities to cater for larger numbers and for an increased proportion of science students, provided the necessary resources are forthcoming. It assumes that such resources can be provided without detriment to other national interests, and in this survey its chief concern is with the possibility of stimulating more of the able boys and girls of the existing school population to take up science instead of the humanities, or encouraging those who leave school at or before sixteen to stay on until university age. It does not consider that there is much scope for attracting to science more of the present population of the sixth forms of grammar schools, and it is the second measure which offers the best prospect of materially increasing the supply of science undergraduates.

The Advisory Council has recently been told by the Ministry of Education and the Scottish Education Department that the number of boys staying on at school is increasing and that in grant-aided and recognized independent schools the number aged 17–18 rose from 23,000 in early 1950 to 27,500 in early 1953. This trend should bring to the universities more potential scientists as well as more potential first-class scientists; but, even taking into account the effect of the post-war bulge in the birth-rate, which from 1960 could give a 25 per cent increase in university students, the figures would have to increase far more to affect materially the number of trained scientists. Moreover, the Council recognizes that there is a risk that such expansion may be at the expense of the numbers of those at present leaving school before the age of seventeen who continue their scientific and technical education on a part-time basis.

Such recognition, however, is as near as the Advisory Council comes in this report to emphasizing that the expansion of scientific and technological education in Britain must proceed in balance with the expansion of technical education, and that some attempt must be made to see that the demands of industry in respect of technicians are also met. The demands for technicians and for technologists and scientists, moreover, are not entirely independent, as in their supply they are interlocked. Indeed, the Advisory Council might well have directed attention to the importance of industry and Government, as well as the universities and research institutions, making the most effective use of their trained scientists. The demand could be checked at least a little if full care were taken to see that highly qualified men are not employed on work which can be carried out no less efficiently by those less highly trained.

In part, this depends on the availability of adequate numbers of laboratory and other technicians, and estimates of the requirements of industry or Government Departments for scientists or technologists which take no account of requirements for technicians are of little value. This consideration equally affects the supply of science teachers, as was fully recognized by the National Advisory Council on the Training and Supply of Teachers in its report on graduate teachers of mathematics and science; the Advisory Council on Scientific Policy endorses the measures recommended in that report in referring to the shortage of science teachers.

Any attempt to encourage more boys to stay on at school until of university age can be of only limited effect as a contribution to increasing the supply of scientists and technologists until the continuous decline in the numbers and quality of science teachers is checked. Broadly speaking, on the question of the shortage of science teachers, as on the supply of scientists, the Advisory Council's views are similar to those of the committee set up at the conference convened by the Federation of British Industries last January. Serious as is the present position, it will become even more serious in the next five or six years unless action is taken very quickly: by 1960 the deficiency of science teachers in the schools may reach 2,300. The Advisory Council believes that so long as there is a real shortage of scientists, the prevailing salary scales will not attract sufficient numbers to teaching. The poor career prospects in comparison with those in industry or Government service are the basis of the shortage, and this report supports the proposals made by the Federation of British Industries Committee for salary revision which would open up prospects of salaries up to £1,500 for, say, five per cent of science graduates engaged in teaching. It gives no indication, however, of the Council's attitude to the more controversial issue of deferment of National Service, on which the Federation of British Industries Committee suggested a reasonable compromise.

The Advisory Council insists that a solution to this problem of the shortage of science teachers is essential; it does not appear to stress sufficiently that a price must be paid to remove the threat which the shortage offers to the supply of trained scientists and technologists, which conditions so largely the effectiveness of our national economy, even if that price be no more than that involved by the proposals of the Federation of British Industries Committee. That price will only be kept so low, however, if vigorous concerted action is taken to promote the ameliorative measures suggested by the Advisory Council or in the reports by other bodies such as the National Advisory Council on the Training and Supply of Teachers and the Federation of British Industries Committee. For example, the Advisory Council, in pointing out that the need is not for narrow specialists in science, suggests that the universities themselves could, by insisting on a proper standard of general education for all candidates, both check over-specialization in the schools and ease the difficulty of finding specialist science teachers for schools. It also comments that, while the standard of first degrees in scientific subjects should be maintained, the proportion of better students who take up science would rise if the universities made it easier for those who had specialized in the humanities at school to turn to science when they reach the universities.

These are sensible suggestions, and it would seem that the *studium generale* or exploratory year which is under trial at the University College of North Staffordshire may have something to offer in this connexion. The Advisory Council, moreover, reaffirms that it is not deprecating the importance of the humanities in the universities, though it believes that education in science is as likely to provide an intellectual stimulus as an education in the classics or history. The emergence of the competent and open-minded man of judgment depends more on the quality of the individual himself and on the quality of the education he has received than on the curriculum.

The Advisory Council has found no evidence that Britain is losing an undue proportion of our best students to other countries, and it points out that the exchange of scientists and technical men between Britain and other Commonwealth countries is desirable on many grounds. The United Kingdom has probably done more to extend the scale of science education since the War than any other major Power; but we had more leeway to make up and were faced with a sterner challenge in maintaining our standard of living. We have still to plan to meet the need for scientists which is implicit in the view that our economy will grow at a reasonable rate and that there will be a rapid increase in our productivity. The Advisory Council rightly remarks that, in the long run, we need more people studying science because of its general educational value; but meanwhile, if a better balance between the supply and demand for scientists and technologists is to be achieved, the various measures now being taken or considered must be implemented with considerably more drive than appears in this report. It must also be insisted that the price to be paid is one which must be met in full, even if sacrifices have to be made elsewhere.

To assess the magnitude of the national demand for scientists and technologists, however, some regard must be had to the national effort; but when the report comes to consider the scale of Government-financed research, its inadequacy is manifest. Now that the Lord President of the Council has become responsible for the Atomic Energy Authority, the Advisory Council will presumably in future have within its competence the bulk of research in applied nuclear physics. Even so, expenditure on defence research may well be on a scale which makes it difficult to assess independently the balance and distribution of the national research effort. The Government expenditure of £20·7 million on civil research in 1954–55, exclusive of the proportion of the £28 million for the universities which is spent on research, has to be set against expenditure on defence research of £160 million or more, and probably up to £100 million on research and development by industry in its own establishments; the chemical industry alone expends something like £12 million and employs some 3,300 scientists, compared with the 4,423 employed under the research councils, etc., according to this report.

Much of this effort lies, of course, strictly outside the scope of the Advisory Council on Scientific Policy, as civil research lies outside that of the Defence Research Policy Committee. At some level, however, the full extent of Government and industrial and defence commitments in research requires review in relation to resources, nor can the Advisory Council discharge its statutory responsibility to the Lord President without some regard to this over-all picture and the way in which it tends to change, as the report itself explicitly admits. The most interesting feature of the summary of research expenditure appended to the present report is indeed the variation which it reveals in the rate of expansion in different fields. While the grand total of Government expenditure on civil research increased roughly sixfold, from £3,640,000 to £20,720,100, between 1939–40 and 1954–55, that on industry and communications and on medical and health purposes increased more than tenfold, from £983,400 to £9,859,000 and from £223,100 to £2,364,600, respectively; while expenditure on research in agriculture, forestry, fisheries and food increased five times, from £1,243,300 to £6,423,600, and that on overseas research increased only from £750,000 to £1,411,200. As the Advisory

Council points out, the scale of Government-financed research in the civil field has increased over the past decade as much as has university education in general, though expenditure on defence research has trebled between 1950 and 1953. Moreover, the rate of increase in expenditure on Government civil research appears to be appreciably greater than that of industry as a whole on research. A survey carried out for the Federation of British Industries in 1950–51 indicated that some three hundred firms were spending £24 million on research and development, an increase of not more than fourfold on expenditure in 1938, although probably fifty per cent greater than in 1945–46. The Association of British Chemical Manufacturers' estimate of £11·2 million expended by the chemical industry as research and development in 1952 represents an increase of some 32 per cent on expenditure in 1948.

The Advisory Council does not in the present report raise the questions whether this relative trend in expansion of research under Government auspices as compared with research within industry itself is desirable, or whether it represents the distribution of man-power and resources likely to yield the best return from the point of view of productivity and the national economy. It recognizes very clearly, however, the implications of such expansion for its own responsibilities, and the section of this report concerned with the exploitation of the civil scientific effort indicates that the Advisory Council is rightly concerned to see that gaps or weaknesses in the national effort are duly repaired or strengthened. On the evidence of this report, the Council's strategy appears to be sound, even if measures to remedy some of the weaknesses it notes might well have been advocated more forcefully. For example, the Advisory Council recognizes the importance of an efficient library service in the exploitation of the results of research, and that it must accept some responsibility for seeing that the national system is adequate and efficient. Nevertheless, in regard to the proposed Science Centre in London, it merely expresses an earnest wish that the necessary resources will be found shortly, and the hope that steps can be taken to implement the scheme for a national library of science and invention without undue delay. The present report will at least keep before the Government the interlocked proposals for a science centre and a central scientific reference library, and what is said in it may encourage Sir Robert Robinson to make a further effort to secure action on the proposals which he did so much to formulate.

The Advisory Council clearly does not regard the time and money required to implement the proposals as valid reasons for delay in bringing these plans to fruition at an early date, and the way in which these plans are related to the dissemination of the results of research and thus to scientific and technological progress may perhaps induce the Government to regard the matter as urgent and of high priority. At present, scientific library facilities in Britain are markedly inferior to those in the United States and in some European countries. The Advisory Council's Standing Committee has been closely concerned in efforts to overcome the immediate difficulties of the Patent Office Library and the Science Library at South Kensington, and during the past year has reported further to the Advisory Council regarding a national library of science and invention. The main recommendations of the report have been endorsed by the Advisory Council, and those quoted by the Council in its present report set forth concisely the case for early action.

The need for a national science lending library cannot be met either by a national science reference library in London or by the development of any existing library on its present site. In the interests of security, the new library should be outside London, preferably in a place easily accessible to the industrial areas of the North and Midlands, for which it could, to a limited extent, also serve as a scientific reference library. Existing collections in the Science Museum, after providing for the needs of the Kensington museums and of the Imperial College of Science and Technology, could supply much of the material for the new library, responsibility for which would be vested in the Department of Scientific and Industrial Research. The new library is thus visualized as an essential part of the expansion of that Department, and its work would be complementary to that of the Department's Intelligence Division, while it would also be the centre of a regional loans system based on selected municipal libraries which would stock and lend the three hundred or so periodicals most used by scientists and engineers in industry.

The bearing of these schemes on the efficient use of scientific and technical man-power might perhaps have been brought out more emphatically; but the Advisory Council's report at least affords the scientist as well as the industrialist an opportunity of pressing for early action by the Government in a matter vitally affecting the exploitation of the results of research, and one in which the first move must come from the Government. Generally, it would seem that the Advisory Council is satisfied with the arrangements to secure the use of science by Government Departments, though it would welcome an increase in the number of administrators with training and experience in scientific work who could bring an understanding of scientific matters to bear in the determination of policy. It also looks for increasing recruitment into the administrative Civil Service of men with a grounding in the sciences.

On the present record of its activities, it is clear that the establishment seven years ago of the Advisory Council on Scientific Policy has been amply justified; but it could be wished that at times it had raised its voice more emphatically and acted more vigorously, and that its influence had been more decisive. As its comments in regard to oceanographic research in this report illustrate, the Advisory Council is able to bring to bear, in borderline fields of science, an informed and concerted opinion and a co-ordinating influence much more immediately effective in implementing co-operation and closing gaps in our research effort than the delayed comments of the shrewdest and most alert Select Committee on Estimates or Committee of Public Accounts.

THE LIFE AND PHILOSOPHY OF ALMROTH WRIGHT

Almroth Wright: Provocative Doctor and Thinker

By Dr. Leonard Colebrook. Pp. xi+286+10 plates. (London: William Heinemann (Medical Books), Ltd., 1954.) 21s. net.

Alethotropic Logic: a Posthumous Work

By Sir Almroth E. Wright. Presented by Giles J. Romanes. Pp. xvi+346+4 plates. (London: William Heinemann, Ltd., 1953.) 25s. net.

THE task of writing a life of Sir Almroth Wright has been well discharged by Dr. Leonard Colebrook, his pupil and collaborator for many years. Wright was half Irish and half Swedish, and laid the foundations of his remarkable career as scientist, writer and philosopher by reading languages and law as well as medicine, and by an apprenticeship in experimental physiology and pathology before he became a bacteriologist.

Wright's greatest achievement was one of his earliest, the introduction of typhoid vaccine and his campaign for its adoption by the Army. He developed a series of ingenious techniques for studying the activity of leucocytes and the body's response to bacterial infection. An early result of these studies was the discovery of opsonin; another was the formulation of views about the treatment of war wounds in 1914–18 which brought him into violent collision with the President of the Royal College of Surgeons. In this polemic he was deservedly described as a "savage controversialist". Of his advocacy of vaccines in the treatment, as distinct from the prevention, of infection, and of his later views on some aspects of immunity, little has survived in the belief and practice of the present day. Of the extensive vocabulary he coined, only two words, opsonin and prophylaxis, have come into general use. His techniques have been little copied, and the method of experiment in the whole animal has been preferred to those he devised employing only living blood *in vitro*. As Dr. Colebrook frequently points out, Wright's many ideas may yet bear fruit, or might have done so but for the revolution which has taken place in the treatment of bacterial infections. Chemotherapy has removed much of the need for other methods which he was trying to develop.

Wright was an innovator to whom progress in his science perhaps owes most because he was "provocative" of enterprise among both his associates and his opponents. His remarkable personal qualities secured him many friends and much influence outside his profession; Bernard Shaw, for example, although contemptuous of orthodox medicine and disbelieving most of the doctrines on which Wright's work was based, had apparently a profound respect for him. The relations between these two men are well described, as indeed is all the more personal side of his life. This is a thoroughly readable and enjoyable biography, and from the scientific point of view it will be valued as a clear and simple account of a series of investigations which are not easy to follow in the original papers.

Wright's grandson, Dr. G. J. Romanes, his secretary, and four other colleagues and friends have collaborated in editing his last written work. "Alethotropic Logic" is an analysis of some of the workings of the human mind, and as such must be judged by psychologists and logicians. Its theme is the search for truth, and the basis on which truth should be accepted: the main argument can be shortly stated by the proposition that emotions are no basis for belief. Christian dogma is severely castigated in many places, as is the feminine mind, and, in Chapter 19, the orthodox statistical method in medicine. There are entertaining chapters or appendixes on the technique of writing, the defects of dictionaries, pictorial art, the relative degrees of intelligence of dogs and bitches, and some of the author's practical inventions. He employs many new words, mainly, like the adjective in the title, of Greek derivation: these are defined in a glossary. There are frequent quotations from a great variety of sources in five languages, admirably illustrating the argument and often epigrammatic. The book can be browsed in profitably for their sake alone, and it has the merit (itself dependent on the defect that this is a rather miscellaneous compilation) of presenting a more complete picture of the author than any other single work he wrote. One thing remains obscure. His favourite saying was: "God offers to every mind its choice between Truth and Repose". What God did he mean? Neither his own book nor his biographer's answers this question.

L. P. GARROD

ROTATING LIQUID MASSES

The Stability of Rotating Liquid Masses

By Dr. R. A. Lyttleton. Pp. vii+150. (Cambridge: At the University Press, 1953.) 35s. net.

A GIVEN mass of uniform incompressible liquid, acted upon by its own gravitation and no external forces, possesses only one configuration of equilibrium relative to a Newtonian frame of reference, and this configuration is a sphere. If the liquid is rotating relative to such a frame, with given angular momentum H, then, relative to a frame rotating with the liquid, there is a spheroidal configuration of equilibrium, a 'Maclaurin spheroid'. If H exceeds a certain critical value H_0, there is another configuration of relative equilibrium, a 'Jacobi ellipsoid'. If H does not exceed a certain further critical value H_1 ($>H_0$), there is still another equilibrium configuration which, when H_1-H is sufficiently small, is the 'pear-shaped' configuration discovered by Poincaré. When H is not too small, there are also configurations in which the liquid forms two bodies in equilibrium relative to a rotating frame; it used to be thought that, for continuously varying H, the series of pear-shaped figures would be continuous with a series of such binary configurations.

Dr. R. A. Lyttleton's book is an account of the theory of the stability, with respect to arbitrary small disturbances, of the various (single-body) configurations. Two sorts of stability have to be considered, 'ordinary' and 'secular', the latter being relevant if there is any internal friction (viscosity) no matter how small. Although the existence of these two sorts is familiar in ordinary dynamics—for example, in the theory of a spinning top—there are pitfalls into which even the most eminent of previous writers on the present subject have stumbled. Dr. Lyttleton starts with an exceedingly lucid exposition of the theory of stability of a general dynamical system; this should be noted by all applied mathematicians, whether or not they are interested in the present applications.

The classical investigations of the problems treated are those of Poincaré, G. H. Darwin, Jeans, Liapounoff and Cartan. The main part of this book consists of a critical re-presentation of the essential theorems obtained by these writers, with some account of the special mathematical methods required. Here again, note should be taken of the general usefulness of Dr. Lyttleton's admirable summary of ellipsoidal harmonic analysis.

The results are, briefly, that the Maclaurin spheroid is thoroughly stable for $H < H_0$, but the secular stability passes to the Jacobi ellipsoid at $H = H_0$. The ellipsoid is thoroughly stable for $H_0 < H < H_1$ and thoroughly unstable for $H > H_1$. The pear-shaped figure is secularly unstable; it cannot, therefore, arise physically, and questions about its mathematical continuity with other forms have no physical significance.

The evolution of a rotating mass of liquid with constant angular momentum and slowly increasing density is the same as that of a mass with constant density and slowly increasing angular momentum. If, then, a rotating mass of liquid (with non-vanishing viscosity) is contracting slowly from an initial state of sufficient distension, it will evolve through the series of Maclaurin spheroids, until an ellipsoidal configuration is possible, and then through the series of Jacobi ellipsoids, until the last stable ellipsoidal configuration is attained. It will *not* then pass into a pear-shaped configuration and will not undergo fission into two bodies describing periodic orbits about each other. It must almost certainly break up, in some way which is not yet calculable, but the fragments must ultimately acquire orbits leading to infinite separation. These conclusions were first correctly formulated by Dr. Lyttleton himself and are cogently stated in his final chapter on "Cosmogonical Implications". This chapter offers some constructive suggestions about the possible rotational disruption of primitive planets and the formation of satellites in the solar system. But many readers will be more interested in the demonstration that binary stars cannot have been formed by rotational fission. A uniform liquid mass is, of course, an unrealistic representation of an actual star, but certain of Dr. Lyttleton's arguments are not restricted to this case and suffice to establish the result generally. In this connexion, Dr. Lyttleton justifiably criticizes some of Jeans's interpretations of the stability theory: but it should be more widely known that, for reasons other than Lyttleton's, Jeans himself rejected the fission theory of binary stars ("Universe Around Us" (fourth ed., Cambridge, 1944); pp. 227–235).

Dr. Lyttleton's book is clearly going to be the standard work on a subject that must form the basis for future investigations which can be expected to be of great significance.

W. H. McCrea

WRITING FOR ENGINEERS

Engineers as Writers

Growth of a Literature. Edited with Introductions and Critical Comments by Walter J. Miller and Leo E. A. Saidla. Pp. xii + 340. (New York and Toronto: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1953.) 32*s*. net.

THE reviewer naturally turns with special interest to the last section of this book, entitled "Suggestions for Review of this Book", only to discover that the word is used with the common American meaning of 'second view'—what the English student would call 'revision'. This little disappointment serves to emphasize the basically American outlook of the compilers of this volume, which is a collection of reports, lectures, papers and extracts from books, all written by engineers. Three of the pieces selected are American translations of Latin authors (Frontinus, Vitruvius and Agricola), four of them are from English engineers of the eighteenth and nineteenth centuries (Smeaton, McAdam, Rankine and Parsons), while the remaining eight selections are by Americans (from Wellington, the railway economist, to Ammann, designer of the George Washington Bridge). Even with the earlier work, there is a striking contrast between the English and American idiom, which becomes progressively more marked.

It is generally acknowledged that every effort should be made to train engineering students in clear self-expression, and this collection has been made as an attempt to assist in attaining this object. As the book is intended for class use in engineering schools, the authors have made comments with each chapter and have added suggestions for study and some introductory remarks. Literary criticism of some of the selections included is disarmed by the fact that the authors themselves adopt the attitude that "any study of engineers as writers would be valueless if we did not consider their weaknesses along with their strengths".

The authors have clearly devoted much labour to the selection of their material, as is evidenced by the acknowledgments to no fewer than fifty individuals who have assisted in the undertaking. The result is an undoubtedly interesting collection of items, which it would be inconvenient (though perhaps a valuable experience) for the student himself to extract from the library shelves, were he merely given instead adequate references to each of them. Unfortunately, library facilities would be overwhelmed if an attempt were made to adopt such a scheme in class.

The most serious doubt which comes to mind, on reading this book, is whether the study of such a heterogeneous collection is, in fact, likely to assist a student to clearer, and hence better, writing of his own. Surely the approach most likely to be successful consists of an exhaustive analysis of the methods available for organizing and presenting material, followed by the most thorough criticism of his own efforts at writing and plenty of practice. But there is no reason why a book such as this might not, with some students, act as a stimulus to better writing.

R. H. Macmillan

SOCIAL INSECTS

The Social Insects

By Dr. O. W. Richards. Pp. 219 + 51 plates. (London: Macdonald and Co. (Publishers), Ltd., 1953.) 15*s*. net.

THE need for an authoritative, up-to-date account of the behaviour of social insects in general has become increasingly apparent in recent years, during which the study of the social insects has attracted much attention.

As Prof. Richards himself points out at the beginning of his book, it is to-day quite impossible for any one worker to have made personal observation on all the species of social insects or to have seen all the varieties of behaviour which have been recorded; but it is doubtful whether there is any entomologist better qualified to write on this subject than Prof. Richards. This book will certainly be welcomed by all who are interested in the subject as it brings together in a most readable form the results of many of the more recent investigations on the biology of ants, bees, wasps and termites by workers in various countries.

After dealing briefly with such matters as instinctive behaviour, learning and orientation, the author goes on to discuss, in the first chapter, the probable way in which insect social behaviour evolved from the solitary behaviour exhibited by most insects, through various sub-social stages such as those shown by the common earwig, some dung beetles, bees and wasps, to the elaborate social behaviour of ants, honeybees, termites and some wasps.

In subsequent chapters many aspects of the behaviour of solitary and social wasps, of solitary and social bees, including humble bees and stingless bees as well as honeybees, and of both ants and termites are described. In a most valuable chapter dealing with social parasites the author expounds theories of the origin of the cuckoo bees and wasps which to-day do not possess any worker castes, and also discusses the development of cuckoo habits in ants, which exhibit all sorts of stages in the development of such behaviour, ending up in workerless, degenerate parasites.

When writing of the termites Prof. Richards stresses the fact that, although they show certain remarkable analogies with other social insects, in reality the differences between the termites and all other social insects are profound and more important than the resemblances. He traces the peculiarities of the termites to two basic facts about their societies. First, that males and females are represented at all stages and in all castes, this being associated with a different method of sex-determination; and, second, that development is gradual, over a series of moults, with no helpless grub-stage. Thus their whole caste system is much more flexible and complicated.

In a most stimulating final chapter the author discusses some of the problems which social animals have had to overcome during the course of their evolution.

This is certainly a book which can be recommended unreservedly to all students of animal behaviour, one's only regret being that it is not longer.

C. G. BUTLER

SOCIAL LIFE AND PHILOSOPHY OF ABORIGINES

The World of Primitive Man

By Paul Radin. (Life of Science Library No. 26.) Pp. xi+370. (New York: Henry Schuman, Inc., 1953.) 5 dollars.

ALTHOUGH this book contains many original, and often profound, observations on the mind and customs of primitive man, it suffers from the lack of an exact definition of the material studied. The author attempts, we are told, "to portray the civilizations of primitive peoples and the world in which they lived". The use of the past tense here is confusing, for most of the examples given are of present-day tribes and the world in which they are living to-day, contaminated as they have been by Western civilization. The words "primitive" and "aboriginal" are used interchangeably (as well as "civilization" and "culture", a synonym with which many would quarrel). The dictionary defines aboriginal as "indigenous, existing in a land at the dawn of history, or before the arrival of colonists", and the author accepts most African tribes as aboriginal only with "many provisos" for this very reason, because they have been transformed by colonists and invaders. Since most of the material is drawn from contemporary sources (largely the New World), this proviso should, strictly speaking, apply to nearly all of it. If it is an attempt to portray the world in which they lived in the past, this is another matter; but in this case, most of the material would be irrelevant.

There is throughout a rather subjective bias towards the "positive achievements" that "aboriginal philosophers and theorists have made to the history of thought"; the "negative" side (by which is implied magic, and the role of fear) is not stressed. These practices and emotions, the author concludes (contrary to most social anthropologists), "interfere little with the orderly processes of life and do not hinder rational and objective thinking". Taboos, for example, are often winked at, or got round, and examples are given to prove the point. But again, the examples are of present-day tribes, who have had contact with Western civilizations: it is the world in which they are living rather than have lived.

Aboriginal philosophy is summarized as "do what you like, but face the consequences", for every individual has the right not only to the irreducible economic minimum, but also to self-expression and the freedom of movement. The "consequences" may be social ostracism, but imprisonment is an uncommon form of punishment. A murderer is seldom sentenced to death, for death meant an economic weakening of the community and, as such, demanded not simply revenge but also replacement for loss with damages. Law, authority and property are never static, but circulate. The authority of an individual (the author contends) is largely fictitious or symbolic; there is seldom despotism, for power resides in the group. Status is never inherited, it is conferred at puberty, and therefore infanticide is not a crime; on the death of an individual, status or authority reverts to the group and has to be conferred again on another individual by the group. Customs only become law in emergencies, and are not obeyed because of a rigid tradition but only from the conviction that they have worked in the case of the elders. Personal property is reduced to a minimum, and anything above this is kept in compulsory movement; its value becomes enhanced as it passes from one person to the next and, although the owner sees no profit, he gains in prestige by these transactions.

One is left with a rosy picture of the happy savage enjoying "an amazing degree of social and political integration" and "the concept of personal security which transcends all governmental forms and all tribal and group interests and conflicts". In spite of the uncomfortable feeling that this picture is particular rather than general, however, one is also left stimulated, and with a better understanding of the minds of men with different cultures from our own.

SONIA COLE

Principles of Numerical Analysis

By Alston S. Householder. (International Series in Pure and Applied Mathematics.) Pp. xi+274. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 48*s*.

THIS book is not a manual on numerical computation but gives an account of the mathematical principles upon which numerical techniques covering a wide field may be based. It has been written on the assumption that the reader has access to a high-speed digital computor; but techniques for use on hand machines are also treated.

After an introductory chapter, mostly on the estimation of error, methods are described for solving systems of linear equations. The necessary matrix and determinant theory is developed *ab initio*, and is readable by the student who has gone only as far as the calculus in his mathematical training. Next, processes are described for solving non-linear equations. A thorough treatment of iterative methods is included. There is an important chapter on methods for calculating the latent roots and vectors of matrices, and for the inversion of matrices. Some new methods are described and compared with older techniques. The next two chapters deal with interpolation, and with more general methods of approximation. Then there is a chapter on numerical integration and differentiation, and finally a brief chapter—too brief, perhaps—on the Monte Carlo method.

There are some pleasing features about this book. Bibliographical notes appear at the end of each chapter, and the literature is well covered by the extensive bibliography at the end of the book. It is very easy for the reader to find a reference to more detail on any particular item of interest. The material is up to date (1952), and some recent developments have not been noted by the reviewer in any other book. Altogether, the author has been careful in the selection of material and in the method of presentation.

L. S. Goddard

Physical Chemistry of Metals

By Dr. Lawrence S. Darken and Dr. Robert W. Gurry, with a Collection of Problems by Dr. Michael B. Bever. (Metallurgy and Metallurgical Engineering Series.) Pp. ix+535. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 61*s*.

METALLOGRAPHY has been defined as the physical chemistry of the metallic state. In Britain, however, during the past fifteen years or so, attention has, in the main, been directed rather to the somewhat speculative physical aspects of the subject, though an outstanding exception is to be found in the work of Hume-Rothery and his pupils, of which generous acknowledgment is made in this book. In America, however, and by Masing in Germany, the physico-chemical aspects have remained a subject of continued study.

It is probably true that physical chemistry may be studied just as profitably in the melting furnace or heat-treatment plant as in laboratory glassware. Reaction kinetics and the theory of diffusion are examples of this. As metallurgy is being transformed from a craft to a science, although the craft is most emphatically still there, the physico-chemical bases of metallurgical processes, no less than those of metallography itself, are assuming greater and greater importance. It is therefore not without significance that both the authors of this book are connected with the United States Steel Corporation, and the volume which they have produced is one of quite outstanding interest. It should, however, be made clear from the very start that this is no 'technical' treatise. It provides a thoroughly sound treatment of general physical chemistry on classical lines, but in which the various aspects of that science are studied and exemplified from metallurgical and metallographic examples. Although it is primarily intended for the more advanced student of metallurgy, this book might be used with advantage in the teaching in university schools of chemistry. It would, at any rate, introduce a sense of realism in its own branch of that subject which at times is somewhat lacking. The success or otherwise of such an experiment would be a matter of no little interest in the teaching of pure science.

As examples of the sort of treatment adopted, the nucleation of gas bubbles may be cited, which is exemplified by the frothing of the slag in the open-hearth furnace, or that of solid diffusion, where the processes of gas-carburization and welding are similarly employed. The iron–nitrogen and the iron–carbon systems are both considered in detail as examples of particular binary systems; but one of the most interesting chapters in the whole book is that on the liquid state, which might be read with as much profit by the chemist or the physicist. This is metallurgy as a legitimate branch of science in its own right.

F. C. Thompson

Plant Life in Malaya

By Prof. R. E. Holttum. Pp. viii+254. (London: Longmans, Green and Co., Ltd., 1954.) 18*s*. net.

PROF. R. E. HOLTTUM, with some thirty-odd years of personal observations in one of the world's richest and most interesting floristic regions, has placed botanists, both in Malaya and elsewhere, in his debt by the production of this modest but fascinating volume. Into two hundred and fifty pages he has compressed an introductory account of a very complex and diverse subject—plant life in Malaya.

The aim of the book was to select judiciously from a vast amount of material, so that residents, teachers and first-year university students may be introduced on easy terms to some of the more common plants and their structure and mode of life, to species which illustrate growth-forms, the relationships of plants to their environment, floral structure, the biology of fruits and seeds, and so on. These are illustrated by line-drawings and by a wealth of what is evidently the author's personal observation. For the reviewer, at least, an attractive and interesting feature of the book is the author's demonstration of how well such common tropical plants as rubber, coconut, ginger, bamboo and yams, to mention only a few, can be used in teaching some of the elementary lessons in botany.

The curiosities of plant life, in which the region abounds—including saprophytes, parasites, aquatic plants, ant-plants, nest-ferns, climbing ferns, etc.—are also described and illustrated. In the final chapter, the author seizes on a theme that seldom fails to touch the imagination, namely, the tropical forest in all its extravagance and diversity, as a community of interdependent organisms. The effects of destroying extensive forest areas in the interests of agriculture are also expounded and discussed. This compact volume might well be used as part of the general reading of students of botany in British universities.

C. W. Wardlaw

DEVELOPMENT OF LOGICAL AND MATHEMATICAL CONCEPTS: PIAGET'S RECENT PSYCHOLOGICAL STUDIES

By DR. W. MAYS
Department of Philosophy, University of Manchester

JEAN PIAGET'S reputation as a psychologist in Great Britain is largely based upon a series of books written during 1925–32 dealing with the development of thought, language and moral judgment in the child. But, as he himself points out, this work was merely a prolegomena to his later investigations extending from 1937 to the present day, and reported on in sixteen books and numerous articles. But though these researches are both theoretically and experimentally an advance upon his earlier work, they have, however, had little effect on English psychological thought. (Prof. L. S. Hearnshaw, in his presidential address to Section J of the British Association, 1954, directs attention to the comparative neglect of Piaget's more recent investigations by British and American psychologists.) This is probably due to Piaget's introduction of a new and complex terminology, his use of symbolic logic, and the fact that his most important work remains untranslated. Further, these studies deal with a field which in the past has been the natural preserve of the philosopher and methodologist of science.

A. Piaget's Early Work on Child Thought and Logic[1]

Piaget (now professor of psychology in the Universities of Paris and Geneva) largely concerns himself in this work with investigating the various kinds of thought activity entering into the intellectual behaviour of the child. He criticizes the method of intelligence testing as a tool for investigating child thought, since (*a*) the test-questions and test-conditions under which the test is given are stereotyped in character, and (*b*) the use of a fixed questionnaire neglects the spontaneous answers of the child. Piaget's method in some ways resembles that of the clinical psychologist, since he attempts to make the child talk freely, varying the questions according to the situation.

Piaget distinguishes between ego-centric thought, and communicable thought depending on demonstration. In the former, in which the child uses thought largely as a means for satisfying his desires rather than convincing others, little value is attached to proof. Thought on this level is largely intuitive and operates through subjective schemata. Up to about the age of 7–8, children's concepts have a certain fluidity about them and vary imperceptibly throughout a reasoning process. The child tends to argue from particular to particular and has difficulty in coping with syllogistic and analytic reasoning. Piaget further demonstrates that the conceptual apparatus by which the child orders the world around him is of a much more naïve variety than had previously been suspected.

B. Experiments on the Development of Logical and Mathematical Concepts[2]

Starting from these earlier studies, Piaget set out to make a more detailed experimental study of the way logical and mathematical concepts develop in the child. What is really important about Piaget's approach is that it gives us for the first time a method of testing experimentally many of the concepts and principles which philosophers have discussed in the past on a purely *a priori* level.

Piaget's subjects were children aged 4–12, observed individually. The experimenter performs in front of them experiments on familiar objects (beads, counters, modelling clay, dolls, etc.) and they are asked to predict their outcome. Further questions are put to them to find out how they interpret these experiments.

(1) *The development of the concepts of quantity, weight and volume*[3]. The concept of quantity has for Piaget essentially a logical character. An example of the type of experiment used by him to study its development is given below.

Two identical vessels, A_1 and A_2, are filled to the same level with a coloured liquid. Half of the contents of A_2 are then poured into a vessel B_1 and the other half into a vessel B_2 (both the same size as A_2). The child is then asked if the quantity of liquid in A_1, and that in B_1 and B_2, remain the same. Young children of about 4–6 assert that the quantities are now unequal; some note that the levels of B_1 and B_2 are lower than that of A_1, while others, who note that the liquid is now contained in two vessels, believe that B_1 and B_2 contain together more than A_1.

The child only arrives at the concept of conservation of quantity when he knows how to restore the original state of the liquid by pouring the contents of B_1 and B_2 back into A_2. He is now able to grasp that the diminution in the height of the level of the liquid is compensated by an increase in the number of containers. For Piaget, 'reversibility', namely, the ability to produce in thought for any set of activities a corresponding reverse procedure, is essential for any form of mental experimentation as well as logical inference.

Other experiments of this series use different types of material, such as balls of clay moulded into different shapes and collections of beads. Piaget also demonstrates that the related concepts of weight and volume which appear at about 9–11 and 11–12 on the average are only acquired after the concept of quantity has been formed at about 7–8.

(2) *The development of the concept of number*[4]. In these experiments the child is required to establish a term-to-term correspondence between different collections of objects (for example, flowers to vases, glasses to bottles, counters or beads to one another, etc.).

When, for example, a child aged 4–5 is asked to spread out on a table as many red counters as there are in a row of blue counters, he begins by making a row of the same length, using only perceptual criteria. However, if the counters forming one of the two rows are spaced out or closed up a little, he will now believe that the longer row contains more. Number and space are as yet undifferentiated for him, they form a perceptual whole.

But once the concept of the conservation of number has been formed at about 7 years of age, if the intervals of the row are now changed, the child will assert that there has been no change in number. He becomes aware (at least intuitively) that the increase of the length of the row is proportional to the increase of the intervals between the counters, and that re-establishing the original intervals re-establishes the original length of the row. He will be able to match counter to counter and thus demonstrate that the rows are equal.

Piaget believes that his experiments have some relevance to the dispute among mathematicians as to whether number is a primitive intuition or a purely logical notion. He finds that it is difficult to speak of the intuition of an integer before the child's logical concepts of invariance have developed at about 7. Further, the transition to number occurs in the child just when the classifying and ordering activities he uses about objects become related into logical systems. There is thus some resemblance between the way number comes to be constructed in child thought, and the attempt, on a purely normative plane by Russell and others, to define number in logical terms.

(3) *The development of the concepts of time, movement and speed*[5]. The concept of time, far from being an object of *a priori* intuition as the Kantians assumed, also arises at a relatively late stage, since time at first remains confused with space. Piaget demonstrates this by a further series of experiments.

For example, equal quantities of water are allowed to run into two differently shaped vessels (one pear-shaped and the other spherical). Now, despite the fact that the child has observed that the vessels have started and completed filling at the same time, he will assert that, since the level of the water in the pear-shaped vessel appears higher than the other, it has taken longer to fill. Time in this case will only be estimated objectively when the child no longer judges it simply by the increase in the level of the water, but by its increase in relation to the dimensions of the vessel.

Our everyday notion of time is also constructed on similar lines. At first the child confuses the notion of age with that of height or other visible signs of ageing. Age differences are not thought of as constants. A child born at a later date than another may outpace him if he outgrows the latter. Objective time, since it involves the ability to reverse the course of events in thought, also assumes the concept of reversibility.

As time has a complex character, Piaget, acting on a suggestion of Einstein, proceeds to study the more concrete notions of movement and speed, since psychologically they are prior to the notions of time and space. He finds that these concepts, too, are not given as primitive intuitions, but only gradually disengage themselves from perceptual experience. The speed of an object, for example, remains at first confused with the distance run through.

(4) *The development of metric, projective and topological space*[6]. Historically, geometry has developed in several stages. First there arose three-dimensional Euclidean geometry, later projective geometry and finally topology. The development of the concept of space is, Piaget claims, made in the child in precisely the reverse order. The child starts with purely topological notions, continues with projective notions and finally arrives at those dealing with the size and shape of the object. At the age of three the child can, for example, distinguish between open and closed figures. He can do this before he can draw a rectangle and express its Euclidean characteristics (number of sides, angles, etc.). Only at about 7 does the concept of perspective appear, and at about the same time the system of horizontal and vertical axes, the development of which leads to the metric representation of space. Thus the psychological order of development would seem to come much closer to modern geometry's logical order of axiomatic construction than it does to the historical order of discovery.

C. Related Studies

In discussing the concept of chance[7], Piaget makes the point that the child is oblivious to this concept as long as he remains incapable of reversible logical operations, that is, until about 7–8. There would thus appear to be a close correlation between the construction of the notion of probability and the development of logical operations. This was already noted by Boole in a somewhat different context when he linked probability with the algebra of logic.

So far as perception is concerned, there is a radical difference between Piaget's views and that of the Gestalt psychologist. For the latter the perceptual constancies of shape and size belong directly to the perceived object and are independent of age and ability. For Piaget, on the other hand, our perception of figures is built up as a result of a series of random eye and other muscular movements which are gradually corrected. Starting from the observable facts of child behaviour, Piaget's work would seem to reinforce some of the conclusions of the cybernetician, since he believes that the logical systems which emerge in child behaviour arise as a result of the child's trial and error activities attaining an *equilibrium*. Piaget is also interested in the neuro-physiological aspects of thought activity. He believes that, with the aid of logical techniques, it may be possible to translate the child's activities of classifying, ordering, setting up correspondences, etc., into neuro-physiological terms.

The most interesting conclusion which emerges from this important series of experimental researches[8] is that mathematical concepts in their psychological development are ultimately based upon simple logical notions. Indeed, it might be said, without undue exaggeration, that Piaget's psychological studies are the genetic counterpart of Russell and Whitehead's attempt in "Principia Mathematica" to put mathematics on to a logical basis.

GERMANIUM AND GALLIUM AND THEIR APPLICATIONS

On September 7, three papers on germanium and gallium were read before Section B (Chemistry) of the British Association. Mr. A. R. Powell gave an account of the occurrence of germanium and gallium in British minerals and their extraction from flue dust, Mr. A. A. Smales discussed problems in the analysis of the raw materials and finished products, and Dr. E. G. James described the scientific and industrial applications of germanium.

Germanium occurs in Britain in the zinc ores of North Wales, the pure zinc blende often containing up to 0·03 per cent of the element; but the quantity of ore mined is insufficient to justify special treatment for the recovery of its germanium content. Germanium and gallium are trace constituents of most coals mined in Britain, except those of Kent and the South Wales anthracites. The amount present varies considerably from a few up to 30 p.p.m., with an average of about 7 p.p.m. This means that more than 1,000 tons of each element are present in the coal mined every year in Britain. But only a very small proportion of this output can be recovered economically. When the coal is burned in domestic grates and industrial furnaces, the soot or flue-dust produced contains only insignificant concentrations of germanium, most remaining with the ash. In the smelting of iron ores the germanium in the fuel passes mostly into the pig iron and then is lost in the slag or fume produced in the open-hearth or Bessemer refining processes. In the coking of coal practically all the germanium and gallium remain with the coke; but here again they are lost when the coke is used for domestic or industrial heating. However, when the coke is converted into producer gas, the sulphur present is sufficient to convert both the rare elements into their volatile lower sulphides, which pass off with the producer gas; on cooling this gas the soot deposited may contain up to 0·5 per cent of each rare element as well as up to 50 per cent of carbon and a large number of other elements. This gas is, however, usually burned while still hot, and then the rare elements are converted into their non-volatile higher oxides which collect in the flue system. In the gasworks much of the producer gas made is used for heating the coking retorts, and the heat of the waste gases from this operation is utilized in waste-heat boilers before the gases pass to the stack. The dusts, which collect in the flues between the boilers and the stack, are at present the principal sources of germanium and gallium in Britain. The amount of the rare elements in the dust varies from almost nothing up to as much as 2·7 per cent, according to the conditions under which the producer is operated and the gases are utilized; the average content of gasworks flue dust is, however, 0·5–0·7 per cent of each of the rare elements. If the coke is used for making water gas, the conditions in the producer are so strongly reducing, owing to the high hydrogen content of the gas, that the volatile compounds of the rare elements are converted into metal which alloys with the common metals, chiefly iron, present in the reduced ash of the coke; consequently, no germanium or gallium is found in the flue dust from burning water gas.

The high affinity of germanium for iron and of gallium for copper is made the basis of the first step in the extraction process. Dust from many gasworks is mixed and analysed, and a charge is made up of dust, fluxes, coke and copper-bearing materials such that, on smelting, a neutral silicate slag is obtained together with a metallic regulus consisting of iron, copper, sulphur and arsenic with which most of the germanium and gallium are alloyed. A small proportion of the rare elements passes into the zinc fume which is evolved during smelting and is recovered from the zinc oxide flue dust which collects in the baghouse. The metallic regulus is broken up and placed on a perforated plate in a large glass tower filled with dilute ferric chloride solution through which a current of chlorine is passed. The resulting exothermic reaction heats the solution to boiling and maintains it in this state until all the regulus is dissolved, loss of volatile constituents being prevented by a reflux condenser at the top of the tower. The concentrated chloride liquor from the towers is transferred to glass stills, treated with sulphuric acid to liberate 6 N hydrochloric acid, and distilled to remove arsenic trichloride and germanium tetrachloride with the hydrochloric acid vapours. The condensate separates into two layers, the upper consisting of 6 N hydrochloric acid containing most of the arsenic chloride and the lower of germanium tetrachloride with 10–15 per cent of arsenic trichloride.

The lower layer is separated and fractionated in an adiabatic column similar to that used in the separation of hydrocarbons in the oil industry. This yields an overhead of germanium tetrachloride containing about 10 p.p.m. of arsenic and a residue of arsenic trichloride almost free from germanium. The distillate is refluxed over copper turnings for some hours and again distilled to yield a distillate with less than 0·05 p.p.m. of arsenic based on its germanium content, the arsenic trichloride present in the fractionated chloride having been converted by the copper into non-volatile copper arsenide and cuprous chloride. The pure germanium tetrachloride is stirred for some hours with sufficient water to hydrolyse it and leave a 6 N hydrochloric acid solution in which the solubility of germanium dioxide is a minimum.

The resulting oxide is collected, washed free from acid, dried at 150° C., and reduced to germanium powder by heating in a rapid current of hydrogen at 650° C.; the powder is then melted in nitrogen or inert gas to obtain an ingot of germanium containing no chemically detectable impurity other than about 0·05 p.p.m. of arsenic. This product is, however, not sufficiently pure for the physicist who, therefore, further refines it by zone melting. In this process a series of molten zones is caused to travel along the ingot so as to collect the impurities and sweep them along to one end. In this way practically all the impurity collects at one end of the ingot, the remainder of which is left in a highly pure form.

Gallium is recovered from the liquid remaining in the stills from which the crude germanium chloride was distilled, by first reducing the ferric salt to ferrous and precipitating the copper, arsenic, antimony and heavy metals by stirring with scrap aluminium. The acidity of the reduced solution is then adjusted to 6 N by adding hydrochloric acid, and the gallium chloride removed by continuously distilling isopropyl ether into the bottom of the vessel containing the stirred solution and allowing the ether to overflow from the top of the vessel back into the ether distillation flask. In this way gallium chloride accumulates in the aqueous layer below the ether in the latter flask. This layer is freed from ether and treated with hydrogen sulphide to remove traces of heavy metals. The purified solution is then made alkaline with sodium hydroxide, filtered, and electrolysed to recover the gallium, which is finally purified by shaking with nitric acid.

So far, little commercial use has been made of gallium; but it has some interesting properties which may in the future find industrial applications. It melts at about 30° C. and boils at above 2,000° C.; but unfortunately the liquid metal attacks at high temperatures all metallic materials of construction now known and reacts with most refractory materials unless completely protected from oxidation; it can, however, be handled in silica ware up to above 1,000° C. in absence of oxygen.

The chief analytical problems associated with germanium and gallium are their determination in ores and coals and the determination of impurities in the purified elements. Traces of gallium can be completely extracted as the oxinate from solutions of pH 2–3 by chloroform and afterwards determined by measuring the fluorescence of the morin compound. Traces of germanium are best recovered by distillation of the chloride or extracting it with carbon tetrachloride; the element can then be determined colorimetrically in the spectrophotometer as the phenylfluorone complex. For the determination of arsenic in germanium oxide or metal chemically, a complex of germanium with oxalic acid must first be prepared; the arsenic can then be extracted by addition of diethylamine diethyldithiocarbamate and shaking with chloroform. The extracted arsenic can be determined spectrophotometrically as the reduced arsenomolybdate complex, or by a modification of the Gutzeit test in which electrolytic hydrogen from a zinc-coated platinum cathode is generated in the solution and then passed over thin cotton string impregnated with mercuric chloride to collect the arsine; the stain is developed by immersion in silver nitrate solution and its length is measured and compared with that of similar stains produced from known amounts of arsenic. The success of both of these methods depends on the absolute freedom of the reagents from arsenic, but of course blanks must be used to correct for traces of arsenic in the reagents. The radioactivation method developed recently at Harwell is designed to overcome this disadvantage; in this method the substance is placed in the pile to convert the inactive arsenic-75 into active arsenic-76, a known amount of inactive arsenic (say 50 mgm.) is added and, after ensuring thorough mixing, the arsenic in the mixture is extracted and determined by any suitable chemical method. The amount of radioactive arsenic is then determined by counting and, since the proportion of the arsenic recovered to arsenic added is known, a simple calculation gives the arsenic in the original material; in this way as little as 10^{-10} parts of arsenic may be estimated with accuracy compared with 2×10^{-8} by chemical methods using a much larger sample.

Very pure germanium is of great importance to the physicist, since it enables him to investigate fundamental processes such as electrical conduction and wave-motion in solids; but the importance of germanium to the electronic engineer depends on the presence of very minute quantities of certain impurities. Germanium free from all impurities would have the relatively high resistivity of 70 ohm-cm. at room temperature, since most of its valence electrons are tightly bound in interatomic bonds leaving very few to conduct current. On replacement of a few germanium atoms in a crystal by arsenic, four of the valence electrons of arsenic form bonds with neighbouring germanium atoms and the fifth becomes free to increase the conductivity of the crystal; such germanium is known as 'n-type' since the current is carried by negative electrons.

On replacing some of the germanium atoms in a crystal by tervalent atoms such as indium, gallium or boron, only three of the four interatomic bonds are filled, and the fourth has a missing electron; the resulting hole behaves as a localized positive charge. The impurity atoms will take an electron from a neighbouring bond in the lattice and the hole is set free to contribute to the conductivity; germanium in which the principal mode of conduction is by holes is known as 'p-type'. Rectifying devices have been made from both p- and n-type germanium and from a combination of both. Generally, the impurity concentration required is very small (10^{-7} to 10^{-9}) and has to be controlled within fine limits if devices with reproducible characteristics are to be produced.

Since germanium is very prone to twin, and twinned crystals are undesirable in rectifying devices, the zone-purified ingot must be converted into a single-crystal ingot. For this purpose the germanium is melted in a crucible and a small seed of single crystal is immersed in the top of the molten germanium, which is then made to solidify on to the seed while the growing crystal is withdrawn very slowly from the melt. The required impurity content is added to the melt before growing the single crystal. The resulting single crystal is cut up into thin slices, which for point-contact devices are cut into sections 1 mm. square and ½ mm. thick. This is attached to a backing, and a fine tungsten wire is arranged to make contact with the face of the germanium under slight pressure. With such a device the current increases rapidly when the whisker is positive with respect to the germanium, but the current is very small when the whisker is negative, up to the turnover voltage, usually well above 100 volts.

The next device to be developed was the point-contact triode, which was the first semi-conductor amplifier. This device consists of a small wafer of n-type germanium, one face of which is soldered to a metal support, while at the other face two fine metal wires make point contacts at a distance apart of less than 0·005 in. If one whisker is biased negatively and the other positively with respect to the base, the device behaves as an amplifier with characteristics similar to those of a thermionic triode. These devices have important applications in computors and oscillators, since the rate of change of collector current with emitter current is about 3. Triodes capable of oscillation at frequencies approaching 100 Mc./sec. have now been developed.

More recently, p–n junction diodes and triodes have been prepared by diffusing indium and antimony or arsenic into the germanium in such a way that one portion of the crystal is p-type and the other n-type, or a central thin portion of p- or n-type separates two outer portions of n- or p-type respectively. Various methods of producing such crystals were described and some of their characteristics illustrated by graphs. Among the important features of these devices are small size, ruggedness, low voltage operation, low power consumption and long life. They suffer, however, from the disadvantages that they are not suitable for operation above about

60° C., and the maximum frequency of operation of triodes is at present limited to 1–2 Mc./sec. Experimental types have, however, been prepared capable of operating up to about 20 Mc./sec. as amplifiers and up to 100 Mc./sec. as oscillators. The first application of these devices to reach commercial production is as a hearing-aid amplifier; but some of the most important applications are likely to be in the telecommunications field, domestic radio and electronic computors. At present the biggest problem with computors is dissipation of the heat generated by the large number of thermionic valves employed. Crystal valves not only remove this handicap but also one triode can be made to do the work of two thermionic valves, thereby simplifying the circuit.

A. R. POWELL

THE RELIEF OF PAIN

IN his presidential address to Section I (Physiology) of the British Association meeting at Oxford, which opened a morning's discussion, Prof. A. D. Macdonald, University of Manchester, stressed the importance of the relief of pain even though chemotherapy now deals so efficiently with the causal organisms of many diseases. When the Section last devoted a day to the problems of pain—in 1939—relief was largely limited to the use of opiates and the rather heroic destruction of pain pathways by surgery or alcohol injections. Since then new synthetic analgesics have been developed along various lines. These drugs have their advantages and disadvantages, and the establishment of their analgesic value in the laboratory is only a first step in the assessment of their clinical possibilities.

Analgesics can be defined as drugs which reduce or relieve the sensation of pain without producing loss of consciousness or parallel depression of other senses. Thus general anæsthetics, while used at times, as in labour in sub-anæsthetic doses, for escape from pain, are not true analgesics nor are they desirable in the everyday treatment of pain. Local anæsthetics are of established value in the treatment of certain localized pains, such as fibrositis, and can give remarkable and sustained relief in suitable cases. The use of this group intravenously for analgesic purposes, though supported by some, is difficult to justify pharmacologically, for most local anæsthetics are rapidly cleared from the blood-stream and their use is not free from the danger of depression of the respiratory centre.

Adrian, while doubting whether pain is as much appreciated at the level of the thalamus as Head maintains, agreed that the basal ganglion and the cortex share in its experience. True analgesics should therefore act at both levels. Tracer technique has not so far indicated marked selective action in these areas. Local application of analgesics to the mid-brain is effective with very small doses; but the precise mechanism of analgesic action is still unknown and does not appear to be due to changes in oxygen consumption.

Prof. Macdonald dealt with methods for the comparative assessment of analgesic drugs in both experimental animals and in man, stressing the large psychological element and the substantial individual variation in such experiments. The need in new analgesics is not so much for substances more potent than opium and its alkaloids or the modifications thereof in therapeutic use, for these are powerful enough. What is wanted is a drug with all the advantages of morphine and none of its disadvantages, and work to this end has followed on various lines, of which the following have been most promising:

(1) Drugs closely related to morphine, of which levorphan is one of the best, while dextromethorphan is interesting because it allays cough in small doses though not analgesic and apparently not a drug of addiction.

(2) Pethidine and related compounds, now widely and successfully used to reduce pain during labour, together with inhalations of nitrous oxide or trichloroethylene.

(3) Methadone and related compounds, which are in the morphine class as analgesics though less effective as narcotics and in the relief of anxiety.

(4) The dithienylbutenylamines, intermediate in activity between pethidine and methadone, but still in the experimental stage.

All these, like morphine, are potential drugs of addiction; this limits their usefulness in chronic non-fatal illness. The potentialities of a new drug as a drug of addiction are often obscure; but there are various methods by which it can be assessed, and these methods were discussed.

The coal tar antipyretic-analgesic group (Fourneau's antalgics) has aroused new interest from the use of phenyl-butazone in the treatment of rheumatic symptoms. This drug has much in common with the now despised or rejected amidopyrine, while some new compounds promise to be more powerful yet safer.

Such drugs as the barbiturates have failed to live up to their original pretension to analgesic activity except in anæsthetic doses; for this purpose the short-acting barbiturates such as sodium thiopentone are increasingly used.

Cannabis, its active constituents and their synthetic substitutes have limited analgesic activity, and therapeutic interest in this group is now largely limited to the treatment of cannabis addiction. To restore morale and maintain confidence, methyl pentynol and chlorpromazine might be more effective. The search for the ideal drug continues, and with so many attacks on the problem a solution will surely be found.

A paper on "Some General Views on Drug Addiction" was read by Dr. P. O. Wolff, of Geneva, chief of the Section of Drugs Liable to Produce Addiction of the World Health Organization. Dr. Wolff said that by accepted definition addiction is a disease, not a crime, and that even when it leads to certain illegal acts these may be symptoms of the disease. The drug peddler, however, should be treated as a potential murderer. Again by definition, addiction differs from habit in that it produces a state of periodic or chronic intoxication detrimental both to the individual and to society. Thus barbiturates, like morphine, cocaine and cannabis resin, are potential drugs of addiction, whereas tobacco is a habit. The symptoms of addiction are the overpowering desire or need to continue the taking and obtaining of the drug by any means, the tendency to increase the dose because of the development of tolerance, and the development of psychological and sometimes physical dependence on its effects.

Addiction is distinctly a human phenomenon. While animal tests of the addictive capacity of a drug might be misleading, Seevers has confidence in his ability to make accurate predictions by his studies on monkeys of the risks of analgesics to induce tolerance and physical dependence in man. Many attempts have been made to account for tolerance. The most satisfactory available hypothesis is still the 'dual action' developed by Tatum, Seevers and Collins, according to which the drug combines with receptors both on the surface and within the nerve cell, which acquires resistance to narcotic effects. Physical dependence denotes the presence of an acquired abnormal state wherein the regular administration of adequate amounts of a drug has, through previous prolonged use, become requisite to physiological equilibrium. The degree of physical dependence often runs parallel with the development of acquired tolerance. Dr. Wolff agreed with Prof. Macdonald that there are good prospects of the discovery of analgesics which will be free from the undesirable properties of morphine while retaining its valuable actions.

Dealing with the work of the World Health Organization on drugs of addiction, Dr. Wolff stressed the importance of an early decision on the convertibility of innocuous compounds into drugs of addiction. A drug is regarded as 'convertible' when the ease of the conversion and the yield constitute a risk to public health, or where there is still uncertainty about that risk. Up to the present, all synthetic analgesics have proved to be addiction-producing. The fact that a drug can be used for a time on many psychologically normal patients under hospital conditions without addiction arising is no guarantee of its safety—a better test is to see whether or not in addicts it could adequately replace their usual drug.

There is a widespread misconception about the prognosis in the addict. Relapse is common because former addicts often remain emotionally disturbed. Yet the high incidence of relapse does not justify a refusal to treat the sufferers any more than in other chronic diseases. There is now a combined approach from the chemical, pharmacological, clinical, mental health, sociological and legal angles, reinforced by well-established international co-operation.

Mr. J. B. Pennybacker, neurological surgeon to the Radcliffe Infirmary, Oxford, read a paper on the contribution of surgery to the relief of pain. Drugs, he maintained, are best used for pains which are not expected to last long, such as that attendant on surgical operations or manipulations. Drugs are also important in painful incurable diseases, some of which being non-fatal cause untold misery over years.

Surgery has been most successful in relieving pain due to mechanical disorders and inflammatory processes. The hope that with expanding knowledge of the anatomy and physiology of the central nervous system many of the intractable pains such as headache, backache, facial neuralgia, post-herpetic neuralgia, painful amputation stumps or phantom limbs and causalgia following peripheral nerve injuries might be relieved by the neurological surgeon has been fulfilled only in part. Increasing knowledge of the pain pathway has increased the possibility of successful relief by dividing that path, and this has been done at various levels.

Section of peripheral nerves has a limited application because most nerves have motor fibres, because of the extensive overlap in innervation, because trophic changes follow complete denervation, and because divided nerves might regenerate and the pain return. Section of posterior nerve roots avoids motor paralysis but the other drawbacks of nerve section remain. Its greatest success is in trigemial neuralgia, probably the most severe of all pains, by section of the root behind the Gasserian ganglion.

The operation of cordotomy (division of the spinothalamic tract) has been practised since 1911, and though still used has not proved the hoped-for panacea, for relief often lasts for only a few months. In other countries small focal lesions have been produced in the optic thalamus, the great sensory nucleus in the base of the brain, using stereo-tactic methods. Excision of the relevant cortical area, which subserves the highest level of sensory perception, unfortunately sacrifices a good deal of ordinary sensation as well as pain, and the pain might persist or recur. Frontal leucotomy sometimes relieves a patient's misery, and he bothers no longer about his pain—or about anything else. Smaller lesions appear justifiable in some cases, to ease the pain of the last few months of a patient's life, not only for the patient's sake but also for the relatives who have to watch and suffer as well.

Mr. Pennybacker referred to the challenge of an ageing population in which the problem of finding relief from pain is increased. He doubts whether the development of 'pain clinics' is the answer, because interest there would be focused on a symptom instead of the disease. He found the greatest encouragement for the neurological surgeon in the discovery, twenty-two years ago, of how sciatica is often due to compression of a nerve root by a rupture of the intervertebral disk. This affords a satisfactory explanation for the pain and a certain method of curing it.

In the subsequent discussion the speakers were asked about the relief of the pain of 'nervous tension' and the value of hypnotism in anaesthesia, in relieving pain and in the treatment of drug addiction. Dr. Wolff and Prof. R. R. MacIntosh expressed doubt about the efficiency of hypnotism unsupported by other measures.

THE VEHICLE AND ROAD SAFETY

THE increasing interest in the scientific attack on problems of road safety was shown by the fact that the whole of one of the opening sessions on September 2 of Section G (Engineering) at the British Association at Oxford was devoted to two papers on the safety of vehicles. The first paper was by Mr. G. Grime, of the Traffic and Safety Division of the Road Research Laboratory, and the second by Mr. D. Bastow, chief engineer, Jowett Cars, Ltd.

Mr. Grime set out to show where improvements are required in the design of vehicles, to demonstrate the urgent need for better maintenance of lights and brakes, and to consider how these improvements might be brought about.

To be able to see well is obviously of the greatest importance to a driver, and, in this connexion, startling figures were given to show the poor state of aim and maintenance of vehicle headlamps. Only about one-half of the headlamps examined in a survey carried out in 1952 were aimed within three degrees of correct aim, while one-sixth had deteriorated so badly that their light intensities were less than one-tenth of what they once were when new. All this leads to the inequalities of illumination which are the most potent factor in causing dazzle and poor seeing.

A similar situation, though not quite so disturbing, exists in regard to the brakes of vehicles in use on the roads of Britain. A survey, made in 1948–50, revealed that about 7 per cent of vehicles require twice as great a distance to stop as that given in the Highway Code for brakes in good condition.

Mr. Grime gave reasons for concluding that the most effective way of making the necessary improvements in the maintenance of the vehicle to overcome present shortcomings in headlights, brakes, etc., is compulsory vehicle inspection. Evidence from the United States suggests that compulsory vehicle inspection and associated safety measures have resulted on the average in a 12 per cent reduction in deaths in the States where it is in force.

Comparatively small changes in the design of vehicles to improve visibility might perhaps lead to substantial reductions in accidents. The right-turning manœuvre is a dangerous one for almost all vehicles, and the fitting of properly designed and placed rear-view mirrors as standard on all vehicles including bicycles was advocated.

In emergency braking, especially on wet roads, steering control may be completely lost if both wheels on either front or rear axle lock. An efficient brake, arranged never to lock any wheel, whatever the friction between tyre and road, would therefore represent an important advance in the design of the vehicle, and would be particularly beneficial to motorcyclists.

American research on the injuries suffered in car accidents shows that much could be done, by redesigning the interior of the car, to minimize the severity of these injuries. The most important requirements are the elimination of sharp edges and points, the fitting of resilient pads at appropriate positions, and the provision of safety belts or other means of holding the occupants in place during the accident. Mr. Grime suggested that the vulnerability of motor-cyclists to injury (about thirty times that of drivers of four-wheeled vehicles) might be reduced by enclosing their vehicles in saloon bodies and perhaps tying the riders into their vehicles with safety belts. There is already a tendency in the direction of making enclosed motorcycles for reasons of weather protection.

Mr. Donald Bastow introduced his paper entitled "Vehicle Design for Safety" by referring to the great possibilities of reducing accidents which were afforded by improvements to the road system of Britain. An experiment by Mr. G. T. Bennett in the County of Oxford showed that, by relatively slight alterations to rural road junctions, a reduction of about one-third in the accident-rate at those junctions had resulted. There was little evidence from insurance premiums that vehicles of particular makes were more liable than others to be involved in accidents, and he considered that accidents were generally the result of human frailties rather than vehicle imperfections.

Like the previous speaker, Mr. Bastow considered that the first and most important safety requirement is all-round visibility, and proceeded to describe the methods employed in measuring and plotting the obstructions to the driver's vision. He considered that curved safety glass had done more than anything else to improve visibility, by enabling windscreen pillars to be placed farther back, and by making possible really large rear windows. Important accessories which are now coming into use on modern cars to improve visibility are windscreen-washers, powerful fresh air heating systems, and electrically heated rear-windows.

For driving in fog, Mr. Bastow advocated the use of headlamps by day to give warning of approach and by night the use of two fog lamps to give a wide spread of light.

Next in importance to visibility comes the controllability of the vehicle, and here the speaker discussed, in simplified form, modern theories of steering, stressing the all-important role of the tyre. For ease of control, particularly by inexpert drivers, an 'understeering', that is, a stable rather than an 'oversteering' or unstable characteristic, is desirable. Springing also influences controllability, and the softer front springing which has become possible with independent front springing has helped in this respect by reducing variations of load on the front wheels.

Two practical problems in maintaining efficient braking are those of adjustment and of overheating with consequent fading of brake efficiency. A new development which may overcome both is the disk brake, with which a greater mechanical advantage may be employed.

Further considerations in favour of a non-locking brake were mentioned. Such a brake is already available for aeroplanes and may eventually become a commercial possibility for road vehicles.

In the discussion which followed the two papers, Mr. L. Bainbridge-Bell mentioned a very simple and cheap brake-testing device made in the form of a rectangular box, of such a size that when placed on a flat horizontal surface in the car, it fell over when a certain deceleration was exceeded.

In reply to a question by Sir Richard Southwell, Mr. Grime gave the results of a series of tests by the Road Research Laboratory comparing yellow with white light for headlamps. Two cars and twenty drivers were employed in the tests, which took place on a track, about half a mile in length, along which unlighted obstacles were placed. The cars were fitted with both white and yellow headlamps of the same design and giving the same beam distribution. They started simultaneously from opposite ends of the track using in turn either the white or the yellow headlights. Drivers were asked to record their preferences both when the opposing car was too far away to produce dazzle and when it was near. Tests were conducted with the track both dry and wet, and with correctly and incorrectly aimed beams. In tests of a different kind, the distances at which test objects could be seen were measured, this time with six observers.

The results may be summarized in the statement that all the differences found were small. The distances at which the target could be distinguished were on the average slightly greater (about 5 per cent) with yellow than with white light, but this increase is not a significant one. In the opinion tests with twenty observers, when there was no opposing glare, there was a significant preference for the white beam. When the cars approached near one another, although more observers considered the yellow beam less glaring than the white, there was a small majority in favour of the all-white system. It may therefore be stated with confidence that changing over to yellow light will not solve the headlight problem.

Dr. E. A. Watson directed attention to Fig. 13 of the first paper, which indicates that there is more glare from the modern British dipped headlamp than from headlamps on American roads. Since modern British and American dipped beams are very similar in characteristics, the difference suggests that British headlights are not properly aimed when they leave the manufacturer or agent.

Dr. Watson deprecated the unsafe practice of driving with sidelights in badly lighted streets.

Mr. B. G. Robbins brought up the question of improved windscreen wipers with blades travelling horizontally across the glass, and Mr. Bastow said that this is quite feasible though expensive. A wiper of this type was on the market some years ago but has been abandoned.

OBITUARIES

Prof. William S. Boulton

The death on September 14 of Prof. William S. Boulton, emeritus professor of geology in the University of Birmingham, in his eighty-eighth year, has removed the last of the Victorian geologists. He was first an assistant of Lapworth's at Mason College, Birmingham, and later studied under Judd at the Royal College of Science, London, heading the examination list in geology. He stayed on for a fourth year as one of two assistants to Lockyer in his work on stellar photography, the other being Richard Gregory, later editor of *Nature*. The Victorians built on broad foundations! In 1890 Boulton returned to Mason College as demonstrator and assistant lecturer under Lapworth, and in 1897 went to University College, Cardiff, as lecturer in geology and geography, becoming professor there on the creation of the University of Wales in 1904.

Under Lapworth, engineering and mining students were taught the principles of geology, with some emphasis on their application to their particular professions, and with field-work as an essential part of the course—a novelty in those days. Boulton carried these ideas to South Wales and did a good deal of proselytizing through the medium of university extension lectures, to which he attracted large audiences, chiefly in the mining towns of the coalfield. He also was a contributor to and editor of a six-volume "Text-book of Practical Coal Mining".

At Cardiff he built up a reputation as a teacher of geology and geography, and as a consulting geologist in coal mining and water supply; and on Lapworth's retirement from Birmingham in 1913 he was appointed as his successor. The First World War interrupted all university work; but after it Boulton brought the whole of the Geology Department under one roof—it had previously been partly in the new buildings at Edgbaston and partly at Mason College—and under his guidance it expanded greatly while retaining the ideals of Lapworth with respect to pure research and the application of academic geology to engineering, mining and later to the oil industry. Boulton became acknowledged as one of the most outstanding authorities on the geological side of water supply, and he practised as a consultant for many years after his retirement from the University on reaching the age limit in 1932.

Boulton rendered public service on the Geological Survey Board, the Safety in Mines Research Board, the Government Inland Water Survey and the Council of the Geological Society; he was president of Section C (Geology) of the British Association in 1916, of the South Staffordshire and Warwickshire Institute of Mining Engineers (1922–23), vice-president of the Geological Society (1934–35) and dean of the Faculty of Science both at Cardiff and Birmingham.

Apart from his investigations in connexion with coal and ironstone mining and water supply, most of which naturally remains unpublished, Boulton's early interests were petrographical. Later he made valuable contributions to our knowledge of the red rocks between the Coal Measures and the Trias in the Midlands; but it is particularly as a teacher, administrator and consultant that Boulton will long be remembered by colleagues and by a host of students now scattered all over the world.

L. J. Wills

Prof. Antonio Minto

Prof. Antonio Minto, whose death is reported at the age of seventy-four, was for long years one of the best known and most influential figures in Italian, especially Etruscan, archæology. As professor in Florence, as 'soprintendente' for northern Etruria, and as president of the Istituto di Studi Etruschi, he came to occupy a commanding position in this field.

Born at Pieve di Sacco near Vicenza in 1880, the first part of his archæological life was spent in Greece, where he worked with Halbherr and Pernier. Then came the First World War. Afterwards he worked in Campania (1922–24), until, in 1924, he was appointed 'soprintendente' in Florence. There he remained until the end of his working career (he retired in 1951), and it is with Florence and northern Etruria that his name will always be particularly associated.

Under his direction the reorganization of the Museo Archeologico in Florence, begun in the reign of Milani, was largely completed. The original home of the Museum, the Palazzo della Crocetta, was enlarged by the addition (1930–40) of the long series of galleries that now house the greater part of the Museo Topografico, and was itself largely rearranged so that a great quantity of material was made readily available to students. The vision that had been Milani's, of Florence as the centre for Etruscan, and indeed Italic, studies, was shared by Minto, although he could never realize it fully. He had to endure the existence of another 'soprintendenza' for southern Etruria and the sight of the rich results of the new excavations at Vulci and Cervetri going to the Villa Giulia in Rome. He was, however, able to bring to birth the Istituto di Studi Etruschi with its home in Florence, and its annual, *Studi Etruschi*, published there (1927 onwards). Moreover, the extraordinarily rich collections of the Florentine museum, logically arranged and fully exhibited, together with the attitude of its directorate that makes study in the museum easy, have enabled it to maintain its position as the best single place in which to study Etruscan civilization.

Minto was not a great original scholar, not an intellect with the imagination to open up vast new vistas: his great service was in making material available and encouraging study. His work in the Museum was one result of this guiding principle. His writings, which were numerous, were nearly all publications of material that came into his control. New finds in his province were usually made known comparatively quickly and comparatively fully. His only two major publications were, characteristically, excavation reports: one of the remarkable early necropolis at Marsiliana d'Albegna excavated by the Prince Don Tommaso Corsini (published in 1921); the other of his own most important excavations, at Populonia (published in 1943). Besides these excavations, he undertook many less exciting investigations, notably at Heba, Saturnia and Sestino, of which notices appeared in the *Notizie degli Scavi*.

W. L. Brown

NEWS and VIEWS

W. C. Gorgas (1854–1920)

One of the world's greatest sanitarians, William Crawford Gorgas, was born a century ago, on October 3, 1854, near Mobile in Alabama. After graduating M.D. at Bellevue Hospital Medical School, New York, in 1879, he joined the Medical Department of the United States Army. An attack of yellow fever at Fort Brown, Texas, rendered him immune from this disease, and as a result he was frequently sent to camps where outbreaks had occurred. In 1898 he was appointed chief sanitary officer in Havana. When the Reed Commission had proved the mode of transmission of yellow fever by *Aedes aegypti*, he began to attack the mosquito's breeding places and in less than eight months succeeded in eradicating the disease from a region where it had existed continuously for one and a half centuries. But for Gorgas, the construction of the Panama Canal could never have been accomplished. Made chief sanitary officer of the Canal Zone in 1904, he converted this 'white man's grave' into a healthy and inhabitable region. His reputation was now world-wide. In 1913 he visited the Transvaal to advise on the control of pneumonia among the native miners of the Rand and afterwards investigated endemic foci of yellow fever in South America for the Rockefeller Foundation's International Health Board. During 1916–18 he served as surgeon-general of the United States Army. On his way to West Africa, he died in London on July 3, 1920, after a cerebral hæmorrhage, and was given a military funeral in St. Paul's Cathedral. During his last illness he was visited by King George V, who conferred an honorary K.C.M.G. upon him.

Second International Conference of Teachers of Geography

In 1951 the British Geographical Association initiated an international conference with a meeting at Sheffield, and in August 1954 Holland acted as host for the second conference, which was attended by 160 delegates from about twenty countries. Wisely the formal work is limited to the thorough discussion of two or three topics, each introduced by a paper and then debated in groups before the group-leaders put questions to the lecturer. In every discipline there is the constant problem : How soon and at what stage should academic advances in the subject—with results which may only be tentative—be introduced into the teaching in schools and colleges ? The Conference agreed that the concept of under-developed lands contains an element of subjective judgment highly dangerous if introduced without the utmost care to children of school age. The idea of different stages in cultural and economic development is better introduced incidentally in the teaching of regions. The separation of physical and human or social geography which exists in Dutch universities was admitted as specially applicable to conditions in a country where vital work in land reclamation and soils is so much to the fore, but generally was regarded as unsuitable elsewhere. The discussion on 'field-work' revealed no exact word or phrase in the languages of Western Europe to cover the outdoor activities of school geography classes now so well known in Britain and voted as desirable elsewhere. The other half of the work of the Conference is for the host country to show in the field as much as possible of modern developments. This the Dutch, under the presidency of Dr. W. J. Jong and with Prof. A. C. de Vooys as organizing secretary, did extremely well—with special emphasis on the problems of the new polders of the erstwhile Zuyder Zee.

Vacation Course in Synoptic Meteorology

For the fifth year in succession, the Royal Meteorological Society, in conjunction with the Council for the Promotion of Field Studies, held a vacation course in elementary synoptic meteorology at the Council's field-centre at Malham Tarn. The course was held this year during August 25–September 1 and was attended by some thirty-five students. The majority of students attending were undergraduates, reading for degrees in mathematics, physics and geography, nearly half the universities in the United Kingdom being represented. The instructors were again Mr. James Paton, Scottish secretary of the Royal Meteorological Society and senior lecturer in meteorological physics in the University of Edinburgh, and Mr. C. D. Ovey, a vice-president of the Royal Meteorological Society and lecturer in geography in the University of Cambridge. Visiting lecturers included Prof. G. Manley, who described the Helm Wind at Crossfell ; Mr. W. V. Lewis, of the Geography Department, University of Cambridge, who gave a talk on the movement of glaciers and process of glacial erosion ; Dr. S. R. Eyre, of the Geography Department, University of Leeds, who gave a lecture on microclimatology of the New South Wales coastal lowland ; Dr. W. A. Fairbairn, of the Department of Forestry, University of Edinburgh, who spoke on climate and forestry ; and Mr. E. G. W. Spence, who explained the construction and use of meteorological instruments. Towards the end of the course a visit was arranged to the Meteorological Office Station at Squires Gate, near Blackpool. An important part of the course consisted of observation work and the plotting of synoptic meteorological data. As in previous years, various education authorities and the Education Department of the R.A.F. made it possible for some of the students to attend the course, which is approved for grants in suitable cases. It is planned to hold a similar course in mid-August 1955 ; in view of the increasing number of applications received, a parallel course in 1955 for sixth-form students, to be held at the Juniper Hall Field Centre of the Council, is at present under consideration.

Archæology in Greece during 1952–53

The annual report for the session 1952–53 of the managing committee of the British School of Archæology at Athens, by J. M. Cook and J. Boardman, entitled "Archæology in Greece, 1952–1953", is reprinted from the *Journal of Hellenic Studies* (Vol. 74, pp. 64+4 plates. London : British School of Archæology at Athens), and summarizes the varied work of the year ending September 1953. The Greeks continue restoring ancient and medieval buildings up and down their country, and the Americans in the Agora at Athens are rebuilding the Stoa of Attalos—a colonnaded block of shops built in the second century B.C.—to serve as their museum and are also preparing to landscape other ruins. This sort of work offends purists ; but ancient sites do not belong only to specialists. Excavators have been busy in Athens, Eleusis, Corinth, Mycenæ, Lerna, Argos, Olympia, Pylos, Crete, Chios, Thasos, Samothrace, and elsewhere ; the most useful results are likely to be for the Bronze Age. More entertaining discoveries are the dedication of the famous prostitute Rhodopis, the helmet of Miltiades (presumably the victor of Marathon), and what—it seems—the Athenians of the fifth century B.C., after archæological examination, wrongly identified as the graves of the Seven against Thebes.

Torquay Natural History Society

The impact of the Second World War of necessity curtailed the activities of the Torquay Natural History Society, and the centenary year of 1944 passed almost unmarked with the exception of a short historical article in the April issue of the *Museums Journal* in that year. Prior to this the Society had published papers from time to time in its *Transactions* on one aspect or another of its development and activities; but the main historical record remains that of Mr. Harford J. Lowe, published in four parts over the years 1909–13, on the growth and history of the Society. This is now more than forty years ago, and A. G. Madan, curator of the Museum, has prepared an account not only to bring the history up to date but also to report on the collections and present-day activities of the Society (*Trans. and Proc. Torquay Nat. Hist. Soc.*, 11, No. 3). Much of the history is concerned with the excavations at Kents Cavern during which considerable evidence was unearthed which threw fresh light on the antiquity of man.

Oil Palm Research

The first annual report of the West African Institute for Oil Palm Research, just published (pp. 1–135. Benin City, Nigeria; and Crown Agents, 4 Millbank, London, S.W.1. 2*s.* 6*d.*), gives an account of the Institute's organization, research and field work for the period 1952–53. The first issue of the Institute's research journal, which contains detailed reports, has already appeared and has been noted in these columns (*Nature*, 173, 19; 1954): and other publications are in preparation. While the scientific staff list still shows a considerable number of vacancies, the research policy, which is here defined in some detail, is being actively carried out in all its many aspects. The present report gives a comprehensive account of field studies, agronomy, chemistry, plant breeding, general botanical studies, pathology and statistics.

Canadian Biological Publications

With the support of the Research Council of Ontario, J. Murray Speirs, Ruth Kingsmill and George W. North, of the Ontario Fisheries Research Laboratory of the University of Toronto, have prepared a bibliography of Canadian Biological Publications for 1949. The bibliography, a most thorough and comprehensive survey, was assembled by searching biological journals in local libraries, and by following leads suggested by correspondents. Medical and commercial papers have been omitted unless the biological content predominated. The bibliography is arranged by subjects, and within the subject by author, publication, date and page. To anyone wishing to know of recent biological events in Canada this survey will be most valuable; its value would be considerably enhanced if its publication coincided more closely with that of the papers mentioned in it. The bibliography is published jointly by the Quebec Biological Bureau and the University of Toronto.

Annals of Library Science

The first number of a new quarterly periodical (1, No. 1; March 1954; published by the Times of India Press, Delhi; Rs. 10; 3 dollars; 20*s.*), edited by Dr. S. R. Ranganathan, contains two articles by Dr. Ranganathan on Depth Classification which include some criticism of the Decimal Classification and describe the emergence of the Colon Classification. The Universal Decimal Classification is also criticized in an article by Faqir Chand. These, like K. A. Isaac's article on dialectics of the Universal Decimal Classification, are continuations from the journal *Abgila*. The issue also contains a glossary of cataloguing firms by K. D. Puranik, a further article by Dr. Ranganathan on a library development plan for Delhi State, and one by G. Otterick and S. Mochlenbrook on training for library service in Sweden.

Callendar's "Radio-Balance" for determining the Thermal Energy of Radiation

In 1910 H. L. Callendar described a thermal-balance device which he called a "radio-balance" and which consisted of a calorimeter for the measurement of radiation in which the quantity of heat to be measured was balanced against the cooling from a Peltier couple. With this device he made measurements of the solar radiation and also of the energy emitted in unit time from a sealed source of radon which had been lent to him by Lord Rutherford. Since then the only other use of a radio-balance appears to be that of F. E. Hoare some twenty years later, who utilized the device to determine the Stefan–Boltzmann radiation constant. However, the radio-balance as an instrument for the measurement of energy dissipation has much to commend it, and the operation of the device has been extensively investigated recently by W. B. Mann (*J. Res. U.S. Nat. Bur. Standards*, 52, 177; April 1954; Research Paper 2486) with the view of its use for the accurate determination of the energy emission from radioactive sources. Several radio-balances were constructed, and the final version consists of two copper cups 13/16 in. long and having internal and external diameters of 0·099 and 0·130 in., respectively. Each cup is mounted on a six-junction constantan-chromel thermopile, and the lower junctions of each thermopile are dipped into silicone oil contained in two small cavities in the lower copper block that constitutes the container of the radio-balance. A constantan-chromel Peltier couple is soldered to the base of each cup. Each cup may be used singly, and the cups may be used together in opposition. In the series of experiments described by W. B. Mann, measurements were confined to radium preparations contained in platinum–iridium needles of 0·5 mm. wall thickness. For an absorption equivalent to 0·126 cm. of lead, a heat emission of 128·9 cal. gm.$^{-1}$ hr.$^{-1}$ was found for radium in equilibrium with its products down to radium D. The estimated accuracy is ± 0·7 per cent. It is stated that it is proposed to apply the radio-balance described to the measurement of the average energy of beta-ray emitters, and a new radio-balance is being constructed for the comparison of the United States and Canadian national radium standards.

Dreyer's Catalogue of Nebulæ and Clusters of Stars

J. L. E. Dreyer's "New General Catalogue of Nebulæ and Clusters of Stars", giving descriptions and positions of all the nebulæ known at the end of 1887, was published in 1888 (*Mem. Roy. Astro. Soc.*, 49, Part 1; 1888), and this was later supplemented by his "Index Catalogue of Nebulæ found in the Years 1888 to 1894, with Notes and Corrections to the New General Catalogue" (*Mem.* 51; 1895) and by the "Second General Catalogue" (*Mem.* 59; 1908), which provided similar data up to the end of 1894. The Royal Astronomical Society decided to reproduce the three sections by photographic means and to include them in one volume under the title "Memoirs of the Royal Astronomical Society. New General Catalogue of Nebulæ and Clusters of Stars (1888). Index Catalogue (1895). Second Index Catalogue (1908)" (from the Society, Burlington House, London, W.1; 1953; £3 10*s.* post free, or £2 10*s.* to Fellows). This is very much more convenient for observers than the three separate volumes and, except for the alteration in the pagination of the two Index Catalogues to follow on from that of the "New General Catalogue", the catalogue has remained unaltered. In its present form this volume should prove very acceptable to observers of nebulæ and clusters.

Design and Accuracy of Volumetric Glassware

THE sixth in the series of "Notes on Applied Science" prepared by the National Physical Laboratory, Teddington, is entitled "Volumetric Glassware: Scientific Aspects of Design and Accuracy" (pp. 22. London: H.M.S.O., 1954; 1*s.* 6*d.* net). It presents the basic scientific information which must be taken into account in the preparation of standards for volumetric glassware and sets out the main features of standardization which are of general applicability in rationalization or verification. The information given is supplementary to that of any test pamphlets issued by the National Physical Laboratory and also to the British Standards issued by the British Standards Institution. The booklet does not discuss techniques of manufacture or the uses to which the glassware is put. It consists of three main sections dealing with the basis of graduation, the construction and verification of apparatus, and the dependence of volume delivered on delivery procedure. The first section contains a clear explanation of the three units of volume in use—the litre, imperial gallon and cubic foot—and the relationship between them; a discussion of the effect of temperature on the capacity of a glass vessel; and the definition of capacity involving either a volume of water or mercury and, in the case of a graduated glass vessel, the precise setting of the liquid meniscus to a horizontal line. Various details of procedure to be adhered to in the cleaning and in the determination of the capacity of a glass vessel are included in the second section. It is emphasized that all traces of detergents, which are now being increasingly used for cleaning glassware, must be carefully removed from volumetric glassware before calibration, otherwise the surface tension of the water used in the calibration, and consequently the shape of the meniscus, will be considerably affected. Also, all determinations of a glass vessel are based ultimately on the gravimetric method, so that when water is used for calibration and high accuracy is required, both the temperature and pressure of the air at the time of weighing should be recorded. The final section contains a detailed discussion of delivery times and drainage times of burettes and pipettes and is illustrated by several graphs and tables. The booklet concludes with a list of references and of British Standards relating to volumetric glassware.

Institution of Gas Engineers: Annual Report

THE ninety-first annual report and accounts of the Council of the Institution of Gas Engineers (Pub. No. 440; pp. 42; from the Institution, London; 1954), presented at the annual general meeting of the Institution in Bournemouth during May 31–June 2, includes a list of communications during the year, and the regulations for the award of the Charles Hunt Memorial Medals in gas engineering are appended. Five supplements to the fourteenth report of the Chairman's Technical Committee were issued during the year by the Gas Works Safety Rules Committee. These were concerned with a model specification for platforms, ladders and stairways to provide means of access to plant, a code of practice for the safe operation of tower purifiers, a note on the operation of electro-detarrers with carburetted water-gas plant, safety recommendations for electrical equipment in gas manufacture, purification and distribution, and additional references to the bibliography of literature relating to accident prevention. A booklet on "Unusual Incidents at Gasworks" was due to be published, and a supplement dealing with the internal protection of gas pipes has been issued by the Pipes Committee.

Museum of Comparative Zoology at Harvard College: Annual Report for 1952–53

THE annual report for 1952–53 of the Museum of Comparative Zoology at Harvard College (pp. 24; from the Museum, Cambridge, Mass., 1953) details the work of an institution which, though burdened with an antiquated name, executes an extremely important task. It is in effect mainly a research institution in which function is deemed of more importance than taxonomy, though studies in the latter are still undertaken. In addition, important additions have been made to the Museum collections, and several expeditions, including a survey of molluscs at the site of the Jim Woodruff Dam at Chattahoochee, Florida, have been undertaken. An impressive list of ninety-five papers published by the staff is some indication of the continued activity of this well-known Museum.

Reactor School at Harwell

As a step towards encouraging industry to play a greater part in the development of atomic power, the United Kingdom Atomic Energy Authority has opened a reactor school at Harwell. The new school will provide, for a fee of £250, a three-months course of training for staff from industrial concerns to learn the techniques by which heat from atomic piles can be converted into useful power. Priority will be given at first to staff of firms already acting as contractors to the Atomic Energy Authority. Some new graduate members of the Authority's own staff will also be trained in the school. Three courses will be held each year, the next in January 1955. The syllabus includes lectures and individual instruction in nuclear physics, reactor physics, metallurgy and reactor engineering, as well as experimental work. Lectures are given by experts drawn from various divisions at Harwell, and by the full-time school staff. Applications for places in the school should be made to the Manager, Reactor School, A.E.R.E., Harwell, Berkshire, and should give sufficient information for the Management Board to assess whether the student has the required academic standard for entry to the School. It is expected that all students will be physics or engineering graduates or else have had considerable theoretical and practical experience in at least one branch of science or engineering. Mathematics up to subsidiary degree standard is necessary, particularly for the reactor physics lectures. The fee of £250 for the course does not include hotel accommodation; but the school is prepared to book hostel, hotel or guest-house places for students as available.

Fourteenth International Horticultural Congress, Scheveningen

The Fourteenth International Horticultural Congress will be held in The Netherlands at Scheveningen during August 29–September 6, 1955. Prior to the Congress, during August 25–27, excursions will be made to scientific institutions and to horticultural districts in The Netherlands. The Congress will consider vegetables and seeds; fruits; flowers and flower bulbs; trees, shrubs and perennials; and tropical and subtropical horticulture and plantation crops. Within each of these sections the following will be discussed: plant breeding and propagation; soils, fertilizers and water supply; plant diseases and pests; environment; and horticultural engineering, technology and technical marketing problems. Twenty minutes will be allowed for reading each paper, with ten minutes for discussion. The language may be English, French or German. The fee for membership of the Congress is 60 guilders (which includes a copy of the proceedings) or 25 guilders for an associate member. Application for membership should be sent to the Secretary of the Congress, Dr. G. de Bakker, Ministry of Agriculture, 30 Bezuidenhout, The Hague, from whom further information can be obtained.

Announcements

The Committee of Privy Council for Medical Research, after consultation with the Medical Research Council and with the president of the Royal Society, has appointed Prof. A. Bradford Hill, professor of medical statistics in the University of London, Prof. G. F. Marrian, professor of chemistry in relation to medicine in the University of Edinburgh, and Prof. G. W. Pickering, professor of medicine in the University of London, to be members of the Medical Research Council; it has also appointed the Honourable Richard Frederick Wood, M.P., to be a member.

The André Dreyfus Foundation has awarded the Dreyfus Prize for 1954 to Dr. Hans Kalmus, of the Galton Laboratory, University College, London. Dr. Kalmus intends to use his prize spending a semester (April–September 1955) in Brazil, working on problems of human genetics.

The Perkin Medal of the Society of Dyers and Colourists has been awarded to Dr. Arthur Zitscher for his work leading to the discovery of the new class of azoic dyes based on the arylamides of *o*-hydroxycarboxylic acids. The presentation will be made at a meeting of the Society to be held in the University of Manchester on October 15, when Dr. Zitscher will deliver a lecture on his work.

The Textile Institute Medal has been awarded to Sir Ernest Goodale, president of the Institute during 1939–40 and chairman of the Institute's London Section during 1950–52; the Medal was inaugurated in 1921 to mark distinguished services to the industry in general and to the Textile Institute in particular. The Warner Memorial Medal, awarded in recognition of outstanding work in textile science and technology, has been awarded to Mr. R. Meredith, of the College of Technology, Manchester.

The Scientific Instrument Manufacturers' Association is arranging an exhibition of electronic aids to production, design and research, under the title "Electronics at Work", to be held in the Chamber of Commerce Hall, Birmingham, during November 23–25. Admission is by ticket obtainable free on request from the Association at 20 Queen Anne Street, London, W.1, or from the Birmingham Chamber of Commerce, the Birmingham Exchange and Engineering Centre, or the Information Department, Birmingham.

The Spectroscopic Panel of the Hydrocarbon Branch of the Institute of Petroleum is arranging a conference on "Molecular Spectroscopy", to be held in the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2, during October 28–29. Further information can be obtained from G. N. Ross, Anglo-Iranian Oil Co., Ltd., Chertsey Road, Sunbury-on-Thames, Middlesex.

A second edition of the "Departmental Handbook" of the New Zealand Department of Scientific and Industrial Research (pp. 68. Wellington: Government Printer, 1954) has been necessitated by departmental reorganization, staff changes and the heavy demand for the first edition. The bulk of the Handbook is given to brief descriptions of the various Divisions, Laboratories, Sections, etc., of the Department, with lists of staff and also the incorporated research associations. These are supplemented by notes on the general organization and administration of the Department, its activities and responsibilities and development, with details of committees and an index. The Handbook is illustrated and is well produced.

The twenty-first annual Christmas symposium of the Division of Industrial and Engineering Chemistry of the American Chemical Society will be held during January 7–8, 1955, the subject being "Pulsatory and Vibrational Phenomena". The symposium will be broad in scope, with papers on the following subjects: shock phenomena; pulse extraction and other vibration devices in chemical engineering process operations; generation and effects, both physical and chemical, of ultrasonic vibrations; vibration problems in combustion; vibration effects on structures and structural materials; and high-frequency heating. Those intending to participate should write to the programme chairman, DeWitt O. Myatt, Atlantic Research Corporation, 901 N. Columbus Street, Alexandria, Virginia.

Erratum. Mr. R. Persson states that in his communication entitled "Measurements on the Neutron Multiplication in a System of Uranium Rods and Ordinary Water", published in *Nature* of August 7, p. 265, the results obtained from formula (4) should be corrected for the diffusion of slow neutrons from the reflector to the core. This correction is important, especially for the most compact lattices, and the experimental points are then in much better agreement with the theoretical curve.

RECRUITMENT IN THE ENGINEERING INDUSTRY IN BRITAIN

A JOINT discussion between Section G (Engineering) and Section L (Education) at the British Association meeting at Oxford on September 7 was opened by Dr. Willis Jackson, director of research and education, Metropolitan-Vickers Electrical Co., Ltd., who emphasized the great gap between the numbers and quality of recruits needed by the engineering industry and the boys actually coming from the schools. He stressed the importance of continued education, general as well as technical, and of systematic practical training. He believes, however, that there is a fundamental change in attitude on this question based on the recognition of its national importance and arising from the increasing number of men in high executive positions who themselves have had a sound engineering education. The engineering industry, Dr. Willis Jackson said, needs recruits at three levels—professional engineers, technicians, and craftsmen. These sometimes overlap; but each has an essential place in the industry, and he believes that it is the facilities for training technicians which are the least satisfactory, partly because the need for training them systematically has not been clearly appreciated. More deliberately organized courses of practical training and technical study are needed here; but Dr. Jackson stressed the need for more flexibility in training all types of recruits, and also the importance of corporate life during industrial training and the value of the activities of apprentice associations.

Dr. Jackson was particularly concerned with the recruitment of professional engineers. The number of corporate members admitted to the Institutions of Civil, Mechanical and Electrical Engineers has increased from 2,741 in 1951 to 3,310 in 1953, of whom 1,444 possessed a university degree, as compared with 1,215 in 1951. Nevertheless, while the facilities for engineering students at the universities have increased, they are not being used: three hundred first-year places in university engineering schools were unfilled this year and two hundred more will be available in the next three years. More disturbing still, in one university thirty per cent of those accepted failed to pass their first-year examination. Dr. Jackson wondered whether we are trying to draw into the university engineering schools boys who would be better served by entering industry as student apprentices. He also thought that there is a need for better means of informing boys and parents as to the nature and prospects of engineering as a career.

Mr. Donald Lindsay, headmaster of Malvern College, who followed, flatly challenged the assumption that it is the business of the grammar school to produce engineers or any other particularly qualified group. The percentage of able boys is limited to about ten per cent of the school population, and this proportion has to supply all the professions with their best men. In his opinion, the school should be neutral, and should not attempt to influence recruitment for any particular profession. Nevertheless, Mr. Lindsay believes that the engineering profession could do more to attract not the outstandingly able boy, who usually knows his own mind, but the less-able boy, who, like his parents, often has the vaguest ideas of what it means to become an engineer. He suggested that the engineering industries could follow the example of the Armed Services in preparing a single-page document explaining clearly methods of entry and age and educational requirements for their various branches. Mr. Lindsay is also concerned at the possible effect on the prospects of the less-able boys of the new certificate examinations at ordinary level, and still more at the consequences for such boys of the shortage of science teachers and especially the decline in quality of science teachers.

Mr. H. A. Warren, principal of East London Technical College, outlining the contribution of the technical colleges to recruitment and training for the engineering industries, pointed out that grammar schools provided 45 per cent of the technical college students who obtained their Higher National Certificate in 1953. He said that the quality of the work of the technical colleges reaches as high a standard as the grade of student entry permits. The standard of teaching is good, the scale of equipment excellent and also the co-operation from industry, and so far as the student is characterized by a narrowness of outlook, it should be corrected by the philosophy and outlook of this age. Technology, he urged, should be restored to the service of the liberal ends of human life and character; and, referring to the proposals for a new national award in technology, Mr. Warren said that not only has any new award to prove its worth, but also it is essential for it to encourage breadth of outlook and height of aspiration, thus bearing witness to those social, cultural and philosophical qualities which were the original characteristics of a university degree.

ATTITUDES TO WORK

IN an address to the Industrial Section of the British Psychological Society*, Prof. L. S. Hearnshaw stated that as soon as psychologists have become convinced that values have a place in the world of fact and not only in the heads of philosophers, and that they are capable of being investigated by empirical means, the main resistances to their study will have been overcome, and one of the chief regulators of human behaviour brought within the framework of psychological study.

The growing number of attitude surveys that have been carried out among industrial workers since the War is a recognition that this area of psychology is industrially important. For the study of attitudes merges necessarily into the study of values. The difficulties confronting the psychologist in these studies are formidable and even discouraging.

The most suggestive observations on attitudes to work have come not from industrial psychologists—with the exception possibly of Mace, who is a man of many parts—but from an economist, like Zweig, a historian, like Carr, a philosopher, like Salmon, or from the mainly amateur members of productivity teams.

On the whole, the studies carried out by industrial psychologists themselves in the field of industrial attitudes have been restricted in their frames of reference. They have been concerned, broadly speaking, with three main topics. First, there have been studies of attitudes to specific features of the industrial environment, to wages and wage systems, security, status, supervision, working conditions, unions, industrial relations policies, types of job, and so on. Secondly, there have been comparative studies of the sort carried out by Marriott in Britain and by various groups in the United States, in which different factories have been compared with regard to attitudes, and an attempt made to link differences in attitude to features of the industrial situation. Thirdly, there have been studies of changes in attitudes resulting from changes in the industrial situation, both planned and unplanned.

---

* *Occupational Psychology*, 28, No. 3 (July 1954)

Attitude studies along these lines have a twofold value. They provide a knowledge of the features within the industrial situation that influence and modify attitudes, and they provide local knowledge of attitudes to various situations which is of diagnostic value in troubled industrial conditions and a pointer to management.

In modern technical civilizations work has increasingly become a demarcated area of life. There is for more and more people a recognizable meaning in phrases such as 'on the job', 'working hours', 'retirement', in a sense quite unlike anything that obtains, or has obtained, in a simpler peasant or craft economy. A characteristic feature of work is that it is an activity performed under obligation. The individual undertakes to carry out certain duties (this word in itself is significant) in a certain manner, and usually, though not always, to be in certain places at certain times.

There are other attributes of work such as the fact that it usually implies activity continued over a period of time, perhaps a lifetime, and pursued with some regularity—odd jobs are the vanishing point of work—and also the fact that it is commonly integrated into the economic system.

If work is a demarcated area of life, this area can be evaluated in importance in relation to other areas. An individual's attitude to work will partly depend upon this evaluation. Secondly, if work implies obligations, an individual's attitude to work depends partly on his grasp and his acceptance of these obligations, and the qualitative standards of performance which serve as his norms or models.

Certain broad conclusions seem clearly to emerge from cross-cultural studies of this kind and to confirm qualitative studies which have been made. First, attitudes to work are cultural acquisitions bound up with many features of social organization, economics and ideology, and linked to personality structure; secondly, the roots of these attitudes go deep into the historical past; thirdly, though extremely persistent, such attitudes are not unchangeable.

There is a good deal of clinical and psychoanalytical evidence suggesting that personality structure and attitude to work are closely related, that work is one of several ways of securing reassurance against neurotic anxiety—a way agreeable to some, to others profoundly disagreeable. Attitudes to work cannot be understood except against the whole background of a culture and the predominant personality structure that goes with it.

Attitudes, however, though often persistent and stretching back into history, are not unchanging or unchangeable. Strong attitudes may slowly and imperceptibly erode and decay. New attitudes may emerge in response to the challenges of man or Nature. Although there are difficulties in interpreting this evidence, it all points in the same direction and to suggest that attitudes to work have eroded more in Great Britain than elsewhere. Not much can be done about this until more is known.

Into the problem of attitude to work three lines of research suggest themselves: the comparative, the genetic, and the psychometric.

Less is known about the character structure of the good workman, technician or professional man than the character structure of the young delinquent; the underworld has had more than its share of psychological attention. Attitudes to work are acquired in the process of growing up. What in fact are the formative influences upon which such attitudes primarily depend? What part do family influences play? To what extent in our culture are attitudes to work acquired at school? What is the effect of different types of education, or vocational placement, of the way a young person is introduced to work, of methods of industrial training, of blind-alley jobs? Again, what permanent influence do breaks in continuity of work have—military service, for example, or periods of unemployment? These and numerous other questions can be asked, but scarcely answered.

Work, not in the sense of physical effort, but work as a mastery of technique, as control, attention and service is the lynch-pin of modern society; and work in this sense depends even more than does physical labour on the attitude of those who perform it. Attitude to work is fundamental to the very continuance, still more to the progress, of society. There is no more important question for the industrial psychologist to turn his attention to than the way attitudes to work arise, grow and are transmitted.

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION, AUSTRALIA

ANNUAL REPORT FOR 1952–53

FOLLOWING the practice adopted in the previous report, in the fifth annual report of the Commonwealth Scientific and Industrial Research Organization, Australia, covering the year ended June 30, 1953[*][†], material is arranged according to its subject and not the Division or Section concerned. Expenditure for the year totalled £4,526,270, including £1,044,392 from sources other than the Commonwealth Treasury, notably £327,283 from the Wool Industry Fund and £455,273 from the Wool Research Trust Fund. Continued progress is reported in the erection of new buildings, and the new laboratory for the Division of Tribophysics was practically complete.

Detailed surveys carried out by the Division of Soils covered about seventy thousand acres and broad-scale surveys about fifty thousand square miles, the field-work for about half the Melbourne sheet of a revised soil map of Australia being completed during the year. In soil chemistry, work on manganese-deficient soils continued and that on the ion exchange–pH relations in cation-dominant soils is almost complete. Work is in progress on a modification of the rapid Passon method for determining free carbonates in soils, and factors affecting the growth of strains of *Rhizobium trifolii* in the rhizosphere of subterranean clover have been investigated. Attempts to fractionate humic acid into its colloidal constituents failed.

---

[†] Commonwealth of Australia. Fifth Annual Report of the Commonwealth Scientific and Industrial Research Organization for the Year ending 30th June, 1953 Pp. 191 (Canberra. Government Printer, 1953) 11s.

In the Division of Plant Industry increased emphasis was given to fundamental studies, and work on plant chemistry, biochemistry, physiology, microbiology, genetics and cytology is to be extended. Although no officers were collecting overseas, plant exploration dominated the work of the plant introduction unit. Some of the varieties of tall fescue continued to be outstanding in pasture introduction trials at Armidale, New South Wales, and strains of chick pea from Spain and Eritrea appear to be useful, drought-resistant, quick-growing forage plants. Nearly seven hundred new introductions were established in the quarantine nursery at Strathpine, Queensland, chiefly large collections of pasture and crop plants from Africa. Potato varieties infected with virus X have been successfully reconstituted by treatment with the dye malachite green, and comparative *in vitro* tests have shown that streptomycin and aureomycin are more effective than bacitracin, chloromycetin, terramycin and penicillin in inhibiting growth of *Corynebacterium michiganense*, *Xanthomonas vesicatorium*, *X. phaseoli*, *X. campestris*, *Pseudomonas medicaginis* and *P. syringae*. A start has been made on the determination, from each important group of soil microflora, of the numbers which can normally be expected to be present in known fertile soils at different seasons. It has been shown that the reduction of ferric compounds by bacteria results from reducing conditions caused by dehydrogenase systems, and this type of reduction may be important in supplying plant nutrients from iron and manganese oxides.

Preliminary trials on Golden Delicious, Delicious, Granny Smith and Sturmer apples indicate that storage in low concentrations of oxygen in absence of carbon dioxide gives very promising results, scald and breakdown being reduced and texture greatly improved. Investigations on the effect of nitrogen and plant spacing on leaf quality and also on the effect of temperature on the resistance of tobacco plants carrying the necrotic type of resistance to tobacco mosaic were continued. The prevalence of trashy leaf causes considerable losses to the Australian tobacco industry, and the qualitative and quantitative changes in composition of glasshouse plants submitted to treatments conducive to trashiness are being studied. Trials with potassium, copper, zinc, molybdenum, manganese, iron, magnesium and boron on soils in the Southern Tablelands of New South Wales were maintained, and a programme of work has been initiated which should provide detailed information for the solution of subsidiary nutritional problems in the Ninety-Mile Plain area, particularly relating to zinc and copper requirements and the function of these elements in the general physiology of plants. An attempt is being made to determine whether varieties of oats differ in the efficiency with which they utilize copper within the plant. Studies of the distribution of treeless grasslands in south-eastern Australia in relation to soil, climate and fire are in progress; and a detailed study has been commenced of the rate and nature of the improvement of fertility by subterranean clover in New South Wales. Ecological surveys of pastures continued in the New England region of New South Wales, in south-western Queensland and at Deniliquin, where studies with a range of irrigated pastures on several soil types also continued. Studies at Perth of the factors affecting zinc responses in subterranean clover indicate that high levels of soil moisture increase the zinc requirements and that a high level of available nitrogen hinders the utilization of zinc in the soil. Studies on the black soils of the Darling Downs now completed indicate that nitrogen and sulphur are the primary limiting plant nutrients. The large-scale grazing experiments at Lawes with the grass *Paspalum scrobiculatum* and lucerne indicate that the two plants are complementary in terms of production and in providing an overall balanced diet for stock. The range of concentrations of zinc and copper in subterranean clover and lucerne on soils of the Coonalpyn Downs has been investigated as an aid to the diagnosis of incipient deficiency of zinc and copper, and preliminary studies indicate that 3-(*p*-chlorophenyl)-1 : 1-dimethylurea is a powerful herbicide, acting chiefly through the root system.

The Irrigation Research Station at Merbein, Victoria, where a programme of research on breeding tomatoes resistant to nematode and other pests and diseases has proceeded for some years, is broadening its interest in nematology, while much of the work of the Irrigation Research Station at Griffith, New South Wales, has been concerned with the principles and methods of applying water, and the removal of surplus water by drainage. Only slow progress is reported with the establishment of the Sheep Biology Laboratory at Prospect Hill, Parramatta, Sydney, where basic physiological and biological studies of the sheep are to be concentrated. At the National Cattle Breeding Station, Belmont, Rockhampton, methods so far adopted to control infestation by tick (*Boophilus microplus*) appear to be of limited value. The investigation of breeding systems at the Poultry Research Centre, Warribee, Victoria, indicates that the most effective way of improving characters of a quantitative nature with low heritability in a pure-bred population is by selection of genetically superior parents, which are discovered by progeny or sib-testing, or both, and by mating to avoid close in-breeding. Experiments on nutrition and wool production have been extended to provide further knowledge of the metabolism and utilization of methionine, which is convertible *in vivo* to cystine, the main amino-acid in wool keratin. Studies of the physiology of the wool follicles have also been initiated to extend existing knowledge of the process of keratinization. The effects of insulin on sheep and lambs have been studied further, and studies of the relations between vitamin B$_{12}$ and cobalt ingestion in the sheep have shown that the syndrome of cobalt deficiency is due to vitamin B$_{12}$ deficiency.

The Animal Genetics Section has undertaken a survey which is designed to indicate the total variation between sheep throughout Australia in quantity and quality of wool production and the fraction of variation which can be apportioned to genetic and other causes. Further observations have been made on the relation of particle size of phenothiazine to its anthelmintic efficiency, the mode of action of phenothiazine and related compounds, the techniques of drenching sheep and resistance to nematode parasites. With proper dipping technique, at the concentration generally recommended, benzene hexachloride promises to eradicate *Linognathus ovillus* on sheep. Further work on pleuro-pneumonia of cattle is reported, on mastitis in dairy cattle, on brucellosis in cattle and on infectious bovine ophthalmia. Further work has shown that loss of efficiency of benzene hexachloride dipping fluids is related to a selective depletion of the toxic gamma isomer.

In the Division of Entomology the Biological Control Section has intensified its work on the green vegetable bug and is endeavouring to establish parasites of the oriental fruit fly which will give some control of the Queensland fruit fly. Promising methods of controlling cattle tick and lucerne flea have been evolved, and a new virus attacking a pasture caterpillar has been discovered. Periodical surveys of the main infestation areas of St. John's wort (*Hypericum perforatum*) continued, and long-term field studies on insect populations were commenced. Field experiments with DDT indicate that very satisfactory control of the earth mite can be achieved by proper application, and a large-scale eradication campaign against the Argentine ant is to be carried out in an area of 1·5 square miles near Sydney. Some progress is reported towards the development of an insect-proof packing material.

The Wild Life Survey Section shifted its interest in myxomatosis from extensive survey to more intensive studies of special aspects of this problem. Joint investigations with the Tasmanian Fauna Board on the economic biology of the mutton bird (*Puffinus tenuirostris*) were continued in the Furneaux Group and extended to Trefoil Island. An investigation of the role of the straw-necked ibis (*Threskiornis spinicollis*) and the white ibis (*T. molucca*) in the natural control of locusts and to define measures for the preservation of their breeding haunts is under consideration, and the Section is to undertake the establishment of a national bird-ringing scheme. The Land Research and Regional Survey Section has since 1946 completed surveys of 223,000 square miles of under-developed regions in northern Australia, and a second unit is about to commence a survey of the Buna region of Papua. These broad-scale ecological studies determine both the distribution of the native vegetation and the possibilities of growth and establishment of fresh crop and pasture species. They include the assessment of land-use potential, research into problems of agricultural and pastoral development of the zones, climatological studies and a general topographical survey.

In fisheries research more time is being devoted to observations in south-eastern waters on water and plankton conditions, and studies are being made of gummy shark (*Emissola antarctica*) and the fishes of the continental shelf. Progress is reported in the recording of underwater shoals of pelagic fish by echo-sounding. Much useful information on the transport of small fish fry, particularly *Mugil cephalus*, from the small creeks and estuaries around Moreton Bay, was obtained before the lagoon was rendered useless for experimental purposes by the destruction of the sand barrier. Another fish farm for the culture of mullet fry in Moreton Bay is under construction, and the fish culture experiment at Maianbar is proceeding. A detailed investigation of the 'white crayfish' occurrence in coastal areas was made in December 1952, and preliminary biological surveys of prawns were made in north-west waters of Western Australia. Sufficient data have been collected to interpret and predict changes in the scallop fishery. A spectrophotometric method was devised for the determination of phytoplankton densities.

Special reference is made in the report to the co-operation of the Biochemistry Department of the University of Sydney with the physical chemistry group of the Division of Food Preservation and Transport. During the year, the Division commenced a survey of the nature and extent of wastage in cooked prawns for the Chief Secretary's Department of New South Wales and a survey of the Victorian Fishermen's Co-operative cold stores and their operation for the Victorian Department of Fisheries and Game. The study of the chemical composition of apricots and peaches continued. Experiments to increase the biological efficiency of the freeze-drying process for cultures have commenced, and the sudden rise in respiration about the time of ripening has been investigated in apples and pears. Use of the maturometer has made long-term prediction of pea-crop maturity a practical possibility, but the instrument requires modification for use with green beans. Trials of the removal of 'bloom' from the surface of grapes by immersion in warm ethylene dichloride have been extended to the currant and sultana, and the hot sulphite dip for sultanas has been applied by growers at Woorinen with very satisfactory results. Butter-milk, as well as skim-milk, has now been utilized satisfactorily as an addition to bread. Work on the physiological mechanism by which *Lepidium* spp. causes a high content of indole and skatol in milk and cream has stopped. A stock of efficient single-strain cheese-starter cultures has been established.

The Division of Forest Products has investigated the characteristics of tension in wood by microchemical and X-ray diffraction methods and has constructed a rheometer for measuring ~~stress–strain–time~~ relations on paper strips which will be used to study the relation of physical properties to the structure of paper and also manufacturing problems. The essential changes induced in cellulose fibres by beating, and the relation between the moisture intersection point obtained from strength studies and that determined from shrinkage studies are being investigated, and the increase in apparent density of wood substance with external swelling due to the displacement liquid has been confirmed. A study of the effect in laminated beams of using external laminæ of relatively strong species over a core of lighter and weaker material was completed, the high-pressure pilot plant was in almost continuous operation for the experimental treatment of rail-sleepers for co-operative tests, and a series of tests on the resistance to leaching of nineteen water-borne preservatives has given a valuable picture of the relative permanence of different preservatives. An investigation on the manufacture of plywood from veneers immunized against termite attack was commenced, and a spectrophotometric method developed for determining amino groups.

In the Division of Building Research greater emphasis was given to the work on lightweight aggregates and the use of plaster of paris as a structural material, the long-term study of the mechanism of failure of concrete under load and investigations on foamed concrete continued, and the survey of clay resources and the heavy clay industry in New South Wales and Victoria was completed. In the Wool Textile Research Laboratory at Sydney the study of the physical properties of single fibres is being extended to fibre assemblies and the physical properties underlying textile processes. Other work on wool textiles has included X-ray studies of the transformation of α-keratin to β-keratin, the application of resins to wool, the construction of a Hepp-type of osmometer to determine the mean molecular weight of wool dispersions prepared by extraction with urea-bisulphite solutions and the study of protein structure, while good yields of alcohols have been obtained in small-scale hydrogenation of wool-wax acids at 300° C./4,000 lb. per sq. in. in the presence of copper chromite catalysts. Work on the pilot-plant scale on the aerated retting technique for treating flax was completed, and possibilities of improving flax-scutching machinery were being explored.

The Division of Industrial Chemistry continued its fundamental work on the carbides and iodides of thorium in relation to the thermal deposition of the metal, on the fluorides of cerium and their use as fluorinating agents and on the preparation and properties of titanium nitride, and is to conduct research on a large pilot-plant scale on a new method of treating copper concentrates, sponsored by Mount Lyell and Mount Morgan mining companies. The study of portland cement and pozzolanic cements and the survey of Australian resources of ceramic clays continued. A systematic study of the theoretical and experimental aspects of the chemical effects of high pressure was initiated and the work on the purification of antibiotics by fractional adsorption processes was concluded. A study of the physical and chemical properties of spread monomolecular layers has shown that the monolayer techniques can be used advantageously for determining the general architecture of molecules of between twelve and forty carbon atoms and the position of chemically reactive groups within the molecule. Techniques have been established for obtaining reproducible evaporated films and for measuring their thickness by multiple-beam interferometry, and a novel approach to the spectrochemical estimation of elements, invoking atomic absorption rather than emission, is being developed. In organic chemistry, apart from the chemistry and utilization of wool wax and sugar-cane wax, the research programme is concerned chiefly with the examination of Australian plants for alkaloids of pharmaceutical value and substances toxic to livestock, the kinetics of the phenol–formaldehyde reaction, the general chemistry of long-chain aliphatic compounds and the examination of seed oils from Australian plants.

Some work was done on the application of gravity and magnetic methods of concentration for the recovery of wolfram and scheelite from a fine-grained ore from New South Wales, and an intensive investigation commenced on the flotation of cassiterite. Fuel research included a pilot-scale investigation of the carbonizing properties of Australian coals and of the gasification of Victorian brown coal. Detailed investigations of titanium–tin and titanium–silver alloys were completed, and an X-ray diffraction study of the lower oxides of titanium has assisted the interpretation of the structure of oxide scale layers formed in the oxidation of titanium. The Division of Tribophysics has extended its work to include fundamental studies in metal physics and work on reaction kinetics, and reports major advances in the understanding of distortions produced in metals by plastic deformation. A study of the oxidation of propylene suggests that higher aldehydes are formed as a result of the decomposition of peroxides produced by a similar mechanism to that in the simpler liquid-phase reactions. Work on the thermal conductivities of organic vapours continued.

The Division of Metrology was again mainly occupied with statutory and industrial requirements relating to national standards, but also produced and measured three end-standards and platen for an international intercomparison arranged by the International Bureau of Weights and Measures. In low-temperature physics the Division of Physics began an examination of the thermal conductivity of various metals, and a study of the condensation of vapour on a solid surface has shown that, at very low supersaturations, condensation is due to imperfections of the surface. Research on the theory of optical instruments continued, and considerable progress was made in the construction of equipment for solar research. In electrotechnology work continued on the relation between the chemical and physical structure of organic compounds and their dielectric properties. The Division of Radiophysics continued its fundamental work in rain physics and radio-astronomy and also investigations on electronic computing and radio aids to navigation. Much information has been obtained about ionospheric winds, and the Organization has now embarked on intensive studies of the physics of the atmosphere. The work of the Meteorological Physics Section is directed to a more fundamental understanding of the weather and the physical processes which control it. With its new radio-spectroscope, the Division of Radiophysics has discovered a new phenomenon—the production of 'harmonics' of bursts of radio-emission from the sun.

Much of the work of the Nuclear Physics Section was concerned with angular correlations between particles participating in nuclear reactions, with nuclear energy-level determinations, and with scattering investigations. The cosmic-ray spectrometer determination of the variation of the specific ionization of cosmic-ray mesons as a function of their momentum was completed at Melbourne, and directional measurements of cosmic-ray intensity at Hobart continued. In mathematics the analysis of rainfall records and statistical studies of sheep-breeding continued, and effort was concentrated on the final development and use of the electronic computor, while work is almost complete on the development and application of beam-deflexion valves for digital computing.

A CHAINOMATIC PYCNOMETER FOR THE DETERMINATION OF CHLORINE IN SEA WATER

By D. J. ROCHFORD

Division of Fisheries, Commonwealth Scientific and Industrial Research Organization, Cronulla, N.S.W.

IN the early part of the present century, Nansen[1] used hydrometers for the determination of the salinity of sea water, and this method has been used to a limited extent since that date. However, Nansen was quick to realize the limitations of a hydrometer with an emergent stem, and tried to improve the pycnometric method by using totally immersed floats and holding them in equipoise with added weights. Pettersson[2] greatly improved the original idea of Nansen by using a gold chain as the source of weight, and other mechanical improvements. Petters-

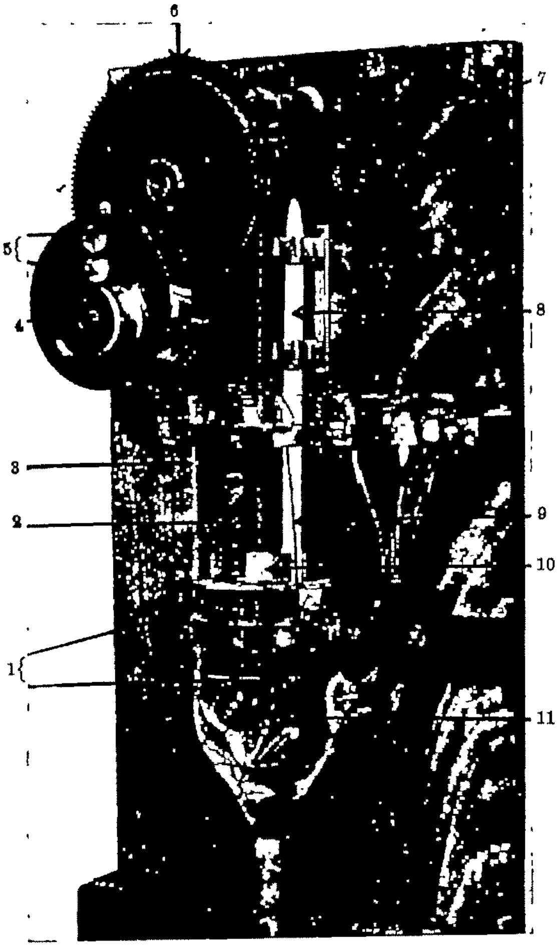

Fig. 1. Front panel of a chainomatic pycnometer. (1) Calibrating lines; (2) gold chain; (3) float chamber; (4) chain-adjusting knob; (5) chain-setting dials; (6) chain drum; (7) tension clutch; (8) thermometer; (9) float lifter; (10) chain guide; (11) float

son described two pycnometers, one with the gold chain as a tail on the float and operated in a tall cylinder in some 500 ml. of sea water, and the other utilizing the chainomatic principle in which gold chain was added link by link from a drum to the top of the float. This second pycnometer was essentially a laboratory instrument, and according to Pettersson, if the temperature was controlled it was capable of high accuracy of density determination.

The Division of Fisheries of the Commonwealth Scientific and Industrial Research Organization has been making extensive investigations of the coastal and estuarine environments of Australia, and a rapid accurate method of determination of chlorine capable of use by field-staff under rather primitive conditions seemed highly desirable. The pycnometric method of salinity estimation was finally chosen because it is a direct physical method, which without the range of equipment needed for a chemical determination or the skill required to construct and maintain electronic equipment is in our experience capable of high accuracy in the hands of semi-skilled operators. Moreover, it is capable of linear operation over the whole range of salinity from sea water down to fresh water.

The chainomatic pycnometer of Pettersson was adapted to our needs and the model now in use possesses the following improvements on his design. (*a*) It is portable, folding as a unit into a carrying case, 15 in. × 7½ in. × 3½ in. (*b*) The glass parts are extremely rugged. (*c*) Certain mechanical features, particularly the tension clutch in Fig. 1 (7) and the 'Perspex' chain guide (10), ensure perfect reproducibility of chain setting and lead to high accuracy of initial determination by users of the instrument. (*d*) The calibration is in $\mathrm{Cl}^{\circ}/_{00}$ units, and calibration graphs enable rapid conversion of instrument data into $\mathrm{Cl}^{\circ}/_{00}$.

The chainomatic pycnometer used by the Division was exhibited at the 8th Pacific Science Congress at Manila in November 1953 and attracted much interest from the oceanographers present. A sample unit has been sent to Canada for use in coastal oceanographical studies. It is hoped that this instrument will be in commercial production by an American firm at an early date. A technical description of the instrument and its use is being submitted for publication.

INTERDEPENDENCE OF TEMPORAL AND AUDITORY JUDGMENTS

By Prof. JOHN COHEN, C. E. M. HANSEL and J. D. SYLVESTER

Department of Psychology, University of Manchester

We have previously presented evidence that judgments of the spatial and temporal components of space-time events are interrelated[1,2]. We have used the term '*kappa*-effect' to denote the influence of the spatial component on judgments of duration to distinguish it from the *tau*-effect[3], which denotes the influence of the temporal component on spatial judgments. In our earlier report we referred briefly to the effects of order of presentation of the display and of visual angle. These effects and the relation between the *kappa* phenomenon and the perception of movement have been more fully described in a paper awaiting publication elsewhere.

In the experiments now to be described we consider the question, raised in the first report, whether the spatial element as such is an essential feature of this type of temporal phenomenon, and whether a delimitation of the time intervals by non-spatial stimuli such as auditory pitch might not produce similar effects.

One effect may be studied by presenting a cycle of three different tones. The flashes of light (as in the previous experiment) are now replaced by brief tones to delimit the temporal intervals, and distance is replaced by tonal interval. A second effect may be studied by means of a temporal interval which is not delimited by two tones but is itself indicated by a continuous single tone. In the first case we are concerned with the influence of tonal intervals on temporal judgment, and in the second case with the influence of continuous tones as such on the temporal judgment.

Effects with Tonal Intervals

(*i*) *Auditory tau.* The subject heard through headphones a repeated succession of three different tones of brief and equal duration and was required to adjust the pitch of the second tone until it seemed

Table 1. AUDITORY *tau* EFFECT FOR TONAL INTERVALS
Mean frequency (and standard deviations) of middle tone from adjustments by subjects ($n = 8$). $T(t_1 + t_2) = 1 \cdot 47$*

$\frac{t_2}{t_1}$	Frequency (c./s.) of first tone (upper figure) and third tone (lower figure)			
	1,000 3,000	2,000 4,000	4,000 2,000	3,000 1,000
0·5	1,676 (230)	2,628 (260)	2,837 (261)	1,921 (292)
1·0	1,874 (211)	2,693 (483)	2,808 (246)	1,838 (274)
2·0	2,068 (276)	2,786 (295)	2,674 (297)	1,725 (245)

* The duration of the complete cycle was 1·5 sec., of which 0·03 sec. was taken up by the onset and fading of the tones necessary to remove clicks.

intermediate in pitch between the first and the third tones. Each cycle of three tones was repeated after an interval of 5/3 of the total cycle. The two successive time intervals (t_1 and t_2) delimited by the three tones could be varied by the experimenter by adjusting the position of the middle tone in the cycle. The three ratios of t_2/t_1 employed were 0·5, 1·0 and 2·0, the total interval remaining constant at 1·5 sec. The frequencies of the first and third tones were set by the experimenter to provide tonal intervals of different magnitude and ascending and descending order. The frequencies used are shown in the column headings of Table 1.

The tones were generated by three audio-oscillators which fed into a mixer embodying a mechanism whereby each tone could build up and fade out in a short period of time so as to remove click disturbances. The sequence of the brief tones was controlled by a continuously rotating switch making contact with three positions, the centre position being variable.

The values in Table 1 are the means for eight subjects, each subject giving two judgments under each of the twelve conditions. It appears from these figures that when the observer is adjusting the second tone so that it seems to him intermediate in pitch between the first and third tones, he makes the tones which are presented closer together in time farther apart in frequency, regardless of the ascending or descending order of the tones. He does this because as, for example, t_2/t_1 is reduced to 0·5 after his adjustments when $t_2/t_1 = 1$, the tones delimiting the shorter time interval (t_2) seem too close together in pitch. In order to make the middle tone appear intermediate in pitch between the first and third, he reduces its frequency, thus increasing the frequency difference between it and the third tone. For example, when $t_2/t_1 = 0 \cdot 5$ and the first and third tones are 1,000 and 3,000 respectively, the mean frequency for the second tone is 1,676 c./s. as compared with 1,874 c./s. when $t_2/t_1 = 1$.

When $t_2/t_1 = 0 \cdot 5$, an interval of 1 sec. is followed by an interval of 0·5 sec. When $t_2/t_1 = 2 \cdot 0$, the reverse is the case. If we combine the figures in Table 2 so as to eliminate the effects of order of presentation of time intervals and ascending and descending order of frequency, there is a mean deviation of 8 per cent when the first and third tones are 1,000 and 3,000 c./s. and about 3 per cent when they are 2,000 and 4,000. Both these deviations are significantly larger than zero at the 0·05 level. Thus the *tau* effect is present under both conditions and is larger when the difference between the outer tones is greater. With the difference between the two tones smaller (2,500, 2,973 c./s.), no significant effect was observed under the above experimental conditions.

Table 2. PERCENTAGE DEVIATION OF JUDGMENTS FOR UNEQUAL TEMPORAL INTERVALS WHEN COMPARED WITH EQUAL TEMPORAL INTERVALS

$\frac{t_2}{t_1}$	Frequency (c./s.) of first tone (upper figure) and third tone (lower figure)			
	1,000 3,000	2,000 4,000	4,000 2,000	3,000 1,000
0·5	− 10·6	− 2·4	1·0	4·6
2·0	10·4	3 5	− 4 8	− 6·1

(*ii*) *Auditory kappa.* The procedure was the same as for the auditory *tau* except that the observer was required to adjust the timing of the middle tone so that t_1 seemed to equal t_2. The frequency of the middle tone was set by the experimenter so as to make three different ratios of tonal intervals.

The results obtained possibly suggest a very slight tendency for comparative judgments of two successive time intervals delimited by successive tonal intervals to be influenced by the relative magnitudes of the two intervals. The results, however, are not statistically significant.

Effect with Continuous Tones

The apparatus was modified so that each temporal interval was indicated by a continuous tone, the second immediately following the first. The tones were set by the experimenter and the subject was required to make an adjustment so that the two tones seemed of equal duration.

Table 3. AUDITORY *kappa* EFFECT FOR CONTINUOUS TONES
Mean for eight subjects when $T(t_1 + t_2) = 1 \cdot 47$ sec.*

(i)		(ii)	(iii)	(iv)	(v)	(vi)
First tone f_1 (c./s.)	Second tone f_2	$\frac{t_2}{t_1}$	t_1 (sec.)	σt_1 (sec.)	t_1' (sec.)	$\frac{t_1'-t_2'}{t_1'} \times 100$ (percentage)
3,000	1,000	1 06	0·715	0·062	0·682	− 15 5
4,000	2,000	0·91	0 771	0·059	0·735	0·0
2,973	2,500	0 95	0·755	0·042	0 720	− 4·2
2,500	2,973	0·83	0 803	0·081	0·765	7·8
2,000	4,000	0·85	0·794	0·072	0·756	5·6
1,000	3,000	0·85	0·793	0·070	0·756	5·6

* See footnote to Table 1.

In col. i of Table 3, we show the pairs of successive tones presented by the experimenter, and col. vi shows the corresponding percentage effect. In col. v a correction has been applied to eliminate time error by multiplying the values in col. iii by a constant derived from the mean of all the readings.

It appears from col. vi that there is a tendency for the time allotted to the higher tone to be less than that allotted to the lower tone. As in the case of auditory *tau* for tonal intervals, the effect appears most marked with the greatest difference in frequency between the two tones.

We have shown that auditory and temporal judgments are interdependent, the *tau* effect appearing most markedly with three brief tones and the *kappa* effect most markedly with two continuous tones. There is a reduced *kappa* effect with three tones, as compared with the corresponding *tau* effect. This is possibly due to the fact that, whereas in the *tau* experiment the subject has to attend to the pitch of the three tones in order to make his adjustment, in the *kappa* experiment he can make his adjustment by disregarding the pitch of the tones as such and attending to them as delimiting temporal intervals.

The subjects' verbal reports support this explanation. In the case of *kappa* with two continuous tones, the subject is compelled to attend to the tones throughout the entire cycle in order to discriminate between them and make his adjustment.

Having demonstrated the interrelation between (i) temporal and spatial and (ii) temporal and auditory judgments, we can now say that the spatial component as such is not an essential feature in these phenomena of interdependence. It may be asked whether the temporal element as such is essential, and whether spatial and auditory judgments are interconnected in the same manner when the temporal component is absent. Preliminary experiments have thus far failed to show an effect comparable to *tau* or *kappa* when the temporal element is absent, though other forms of interrelation between spatial and auditory judgments have been demonstrated in our own laboratory and elsewhere.

These experiments indicate the pervasive character of the temporal component in perception and the need for further study of its effects. [June 22.

SHIELDING EFFICIENCY OF CATIONS

By DR. L. H. AHRENS

Department of Geology and Mineralogy, University of Oxford

It is quite generally accepted that the 8-electron shell is able to shield the nuclear charge of an atom more efficiently than the 18-electron shell. The main object of this communication is to suggest a quantity which may be used for comparing the shielding efficiency (S_{eff}) of all cations; but before doing so, the sense in which shielding efficiency will be used here will be illustrated by two examples.

Consider first the 8- and 18-electron cations, Na$^+$ and Cu$^+$. They both carry unit charge and have the same radius[1,2] (0·95 A.); yet, whereas only 5·1 V. is required to remove an electron from an atom of sodium in sodium vapour, 7·7 V. is required to ionize copper to Cu$^+$. Evidently the $4s$ electron in copper is more tightly held than the $3s$ electron in sodium, and the principal, though not the only, cause may be considered to be due to comparatively poor shielding by the 18-electron shell.

In the above example, singly charged cations were considered; but for more highly charged cations, the equivalent ionization potential will be used—the second for doubly charged cations, the third for trebly charged cations, and so on: thus, comparisons are always made of the energy required to remove one electron—the last one—to give the particular ionic state in question.

As a second example, we may take the pair Zr^{4+} and Hf^{4+}, each with a charge of four and a radius of about 0·79 A.; their fourth ionization potentials are 34 V. and 31 V., respectively. Hence, as it requires more energy to remove the first $4d$ electron from outside the 36-electron krypton core than to remove the first $5d$ electron from outside the 68-electron hafnium core, giving in each case a cation of equal charge and radius, shielding in Zr^{4+} is apparently less efficient than in Hf^{4+}. It will become evident later that, although the ionization potential difference is 3 V. in this pair as compared with 2½ V. for the pair Na$^+$ and Cu$^+$, the shielding efficiency difference between Zr^{4+} and Hf^{4+} is much smaller than in the pair Na$^+$ and Cu$^+$.

In the above examples, radius and charge are the same for the constituents of each pair and nothing can be concluded about how the shielding efficiency in Na$^+$ compares with that in Zr^{4+}, where both radius and charge differ. Consider first the relationship between r and I when charge is kept constant. Attention has been directed[3] to the fact that the relationship

$$I \propto 1/\sqrt{r} \quad (\text{or } I^2 \propto 1/r) \tag{1}$$

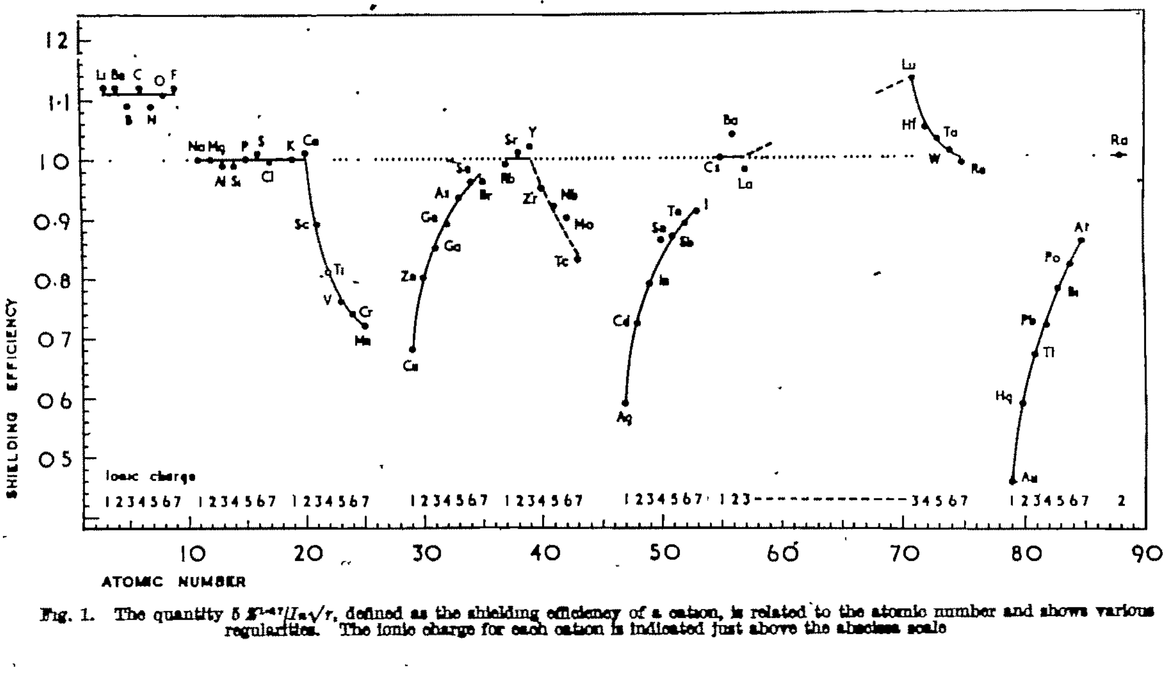

Fig. 1. The quantity $5\,Z^{1\cdot47}/I_z\sqrt{r}$, defined as the shielding efficiency of a cation, is related to the atomic number and shows various regularities. The ionic charge for each cation is indicated just above the abscissa scale

is quite closely followed by the 8-electron groups, Na^+, K^+, Rb^+, Cs^+, and Mg^{2+}, Ca^{2+}, Sr^{2+} and Ba^{2+}. Neither the 2-electron cations, Li^+ and Be^{2+}, nor the 18-electron cations Cu^+, Ag^+, Au^+ and Zn^{2+}, Cd^{2+} and Hg^{2+}, fit the above general relationship. Attention has also been directed[2] to the smooth inverse regularities which exist between r and I_n in such sequences as $Li^+ \rightarrow F^{7+}$; $Na^+ \rightarrow Cl^{7+}$; $K^+ \rightarrow Mn^{7+}$; $Cu^+ \rightarrow Br^{7+}$; $Ag^+ \rightarrow I^{7+}$, etc. Combination of such a regularity for the sequence $Na^+ \rightarrow Cl^{7+}$ with the above inverse-square relationship yields

$$\sqrt{r} \propto Z^{1\cdot27}/I$$
$$\text{or } \sqrt{rI} = K\,Z^{1\cdot27}, \qquad (2)$$

where Z is the ionic charge. With I in volts and r in A., K is found to be $5\cdot00 \pm 0\cdot01$. The extent to which this relationship is obeyed by non-transitional type 8-electron cations may be observed from Table 1.

It is suggested that the quantity $5\,Z^{1\cdot27}/\sqrt{rI}$ be used as a measure of the shielding efficiency of cations, and those cations which obey equation (2) and therefore have $S_{\text{eff}} = 1\cdot00$ (Table 1) will be defined as having normal shielding efficiency.

Table 2 gives values of S_{eff} for cations arranged according to the Periodic Table, whereas Fig. 1 relates S_{eff} to atomic number in consecutive sequences.

The plotted points of highly charged cations in Fig. 1 do not correspond exactly with those of Table 2, as they had been calculated on the basis of a value of 1·26 for the charge exponent and not 1·27. As the differences are insignificant with regard to the various regularities of Fig. 1, it has not been redrawn.

S_{eff} either remains uniform ($Li^+ \rightarrow F^{7+}$, and $Na^+ \rightarrow Cl^{7+}$) or varies regularly toward or away from a value of unity. Entry of $3d$ electrons in particular, and $4d$ and $5d$ to a lesser extent, causes a lowering in the shielding efficiency as defined: the effect increases with charge. The reverse developments take place after completion of the 18-electron shells; and in the sequences $Cu^+ \rightarrow Br^{7+}$, $Ag^+ \rightarrow I^{7+}$ and $Au^+ \rightarrow At^{7+}$, S_{eff} increases with charge and tends to approach unity in each case. The effect of entry of $4f$ electrons is apparently unique, and thus the third ionization potentials of lanthanum and lutetium are almost identical (19 V.); the radius decreases from 1·15 A. to 0·85 A. and hence S_{eff} increases from about unity to 1·14, a maximum value which is apparently very similar in magnitude to that of the 2-electron cations. (The third ionization potentials of Ce^{3+} . Yb^{3+} are not known.) S_{eff} reaches its minimum (0·46) in Au^+.

Table 1. CALCULATED VALUES OF K and S_{eff} (for definition see text)

	$Z^{1\cdot27}$	r (A)	I_n* (V.)	K	S_{eff}

	Ra^{2+} 1·00			Th^{4+} 0·98			

Some ionization potentials are not accurately known (for example, the sixth of tungsten, the seventh of rhenium, astatine, manganese as well as a few others), but their magnitudes are apparently reliable and serve satisfactorily to reveal the main regularities of Fig. 1.

It should be recalled that the radii of Li^+, Na^+, K^+, Rb^+, Cs^+, Mg^{2+}, Ca^{2+}, Sr^{2+}, Ba^{2+}, Ra^{2+}, Y^{3+}, and La^{3+}, are virtually identical with those which may be obtained from internuclear distance measurements in dominantly ionic crystals, and that the others may be derived from them either by calculation[1] or from smooth extrapolations[2]. Thus, although the absolute magnitudes of the radii considered here may not have significance other than for investigations on ionic crystals, it is believed that their relative radii are usually accurately known, and this fact may well be of physical significance. A systematic increase of, say, 50 per cent in all the radii would in no way affect the general regularities which have been noted here (Fig. 1).

Discussion in this communication has been restricted to a suggested definition and measure of shielding efficiency; but its possible significance for determining a variety of physical and chemical properties of elements and their compounds will be discussed elsewhere, together with a detailed account of periodic variations between r, I and Z. The significance of ionization potentials in some of these respects has been noted[2-4]. Some examples of properties which might be determined at least in part by shielding efficiency and which will be considered are: atomic volume, metallic properties of manganese as compared with chlorine and bromine as gases, refractive indices and melting points of ionic compounds, structures of metal – non-metal compounds which have low co-ordination, ability of cations to form complexes in solution and the stability of such complexes, stability of bonds in general, heats of hydration, behaviour of cations in fractionated silicate melts, etc. [May 20.

Longitudinal Distribution of Organic Components of Bone

Previous workers[1] have published results on the variation of nitrogen, collagen and phenolic material along long bones. The variation has now been determined of nitrogen, hydroxyproline, tyrosine, hexose and glycogen.

The femur of a freshly killed eighteen months old male goat was sawn into sections as indicated in Fig. 1 and the epiphyseal plates dissected out. The trabecular sections were sampled well away from the periphery of the bone, freed from blood by washing in a high-pressure water jet and from fat by 48 hr. ether extraction. The shaft sections were well scraped inside and out after the marrow had been scooped out. Ether extraction was unnecessary as the shaft bone contained an insignificant amount of ether-extractable material. The sections were crushed to finer than 100-mesh in a steel hammer mill. All results are in mgm./gm. dry weight, moisture being determined by heating to 105° for 16 hr. and weighing after cooling in a desiccator.

Hexose was determined by a modification of Morris's anthrone method[2]. Bone powder containing 50–100 μgm. equivalent of galactose was weighed and transferred to a 24 mm. × 150 mm. test-tube. 2 ml. of water and 4 ml. freshly prepared anthrone reagent were added, the latter from a broad-tipped pipette. The tube was shaken and stood in a 95° water-bath for 15 min. After cooling and centrifuging, the supernatant was read against a standard galactose solution at 620 mμ. Duplicates agreed to within 2 per cent and recovery of added glucose, galactose or mannose was 98–101 per cent. Glucuronelactone, glucosamine and an artificial gelatin hydrolysate even in concentrations much higher than those occurring in bone neither gave any colour nor did they affect the colour given by hexose. Tryptophan gives a colour with anthrone[3] but is only present in collagen in negligible amount[4]. 100 μgm. galactose or mannose gave a colour density equal to that given by 55 μgm. glucose. In view of the isolation of a galactose–mannose containing polysaccharide from bone[5], results are given as galactose equivalents.

For determination of glycogen, 0·1–0·5 gm. bone was shaken with 5 ml. 30 per cent potassium hydroxide in a 95° water-bath for 1½ hr., making up to volume occasionally with water. The freed glycogen was precipitated and determined essentially as described by Ellis *et al.*[6]. Recovery of glycogen added to bone powder was 85 per cent. Results have been corrected to allow for this.

Hydroxyproline, tyrosine and nitrogen were determined on 6 *N* hydrochloric acid hydrolysates (48 hr., 105°), the acid being removed by repeated evaporation to dryness in a vacuum desiccator. Hydroxyproline was determined by the method of Neumann and Logan[7], tyrosine by that of Udenfriend and Cooper[8] and nitrogen by a micro-Nessler method[9].

The general level of organic components is low in the shaft, rising toward the epiphyses. Collagen and total nitrogen were found to have this type of distribution by previous workers[1]. The galactose curve suggests that non-chondroitin-like polysaccharide material is present, the amount of which is markedly high in the epiphyseal plate. Glycogen varies in a similar manner but at a far lower level. No chemically determined figures for bone glycogen have come to my notice except those of Leynse[10] on rabbit, rat and cat long bones. His results are higher than these, but were obtained on very young animals. Glock[11], using a histological method, finds the glycogen content of rat long bones to decrease sharply with age after the tenth day, becoming about 0·5 mgm./gm. after the fortieth day.

The hydroxyproline curve gives a measure of collagen content probably more significant than previous results based on autoclave soluble-nitrogen determination. The epiphyseal plates do not have a markedly different hydroxyproline content from the other epiphyseal and metaphyseal sections. The nitrogen/hydroxyproline curve suggests the presence of relatively high amounts of non-collagen protein in the epiphyseal plates and proximal metaphyseal trabeculæ. It must be borne in mind that material similar to the alkali-soluble collagen precursor

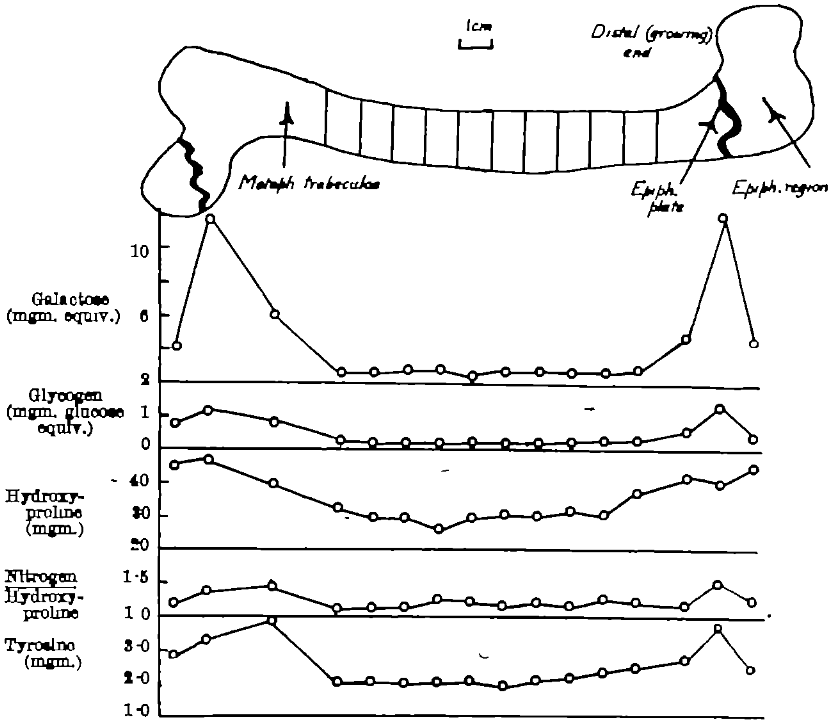

Fig. 1. Longitudinal distribution of organic components in goat femur. Values are in mgm./gm. dry bone powder. Galactose equivalent values do not include glycogen

extractable from skin is very possibly present in relatively high amounts in the metabolically active epiphyseal and metaphyseal areas. As this has a rather higher hydroxyproline and rather lower tyrosine content than collagen as a whole[12], its presence would tend to obscure the contribution of non-collagenous protein, high in tyrosine and without significant hydroxyproline to those areas.

Determination of phenolic material by the Folin–Ciocalteau method[10], on the above and other bones, gave tyrosine equivalents up to 30 per cent higher than those obtained using the more specific method for tyrosine of Udenfriend and Cooper. Thus the presence of small amounts of non-tyrosine phenolic material is indicated.

The results are in general agreement with a previous less-detailed series of determinations carried out on an eighteen months goat ulna.

I thank Dr. J. Eastoe, Dr. H. J. Rogers and Dr. T. F. Dixon for discussing this work with me, and the latter also for suggesting its subject. I also thank Mrs. N. Mendlesohn for the nitrogen determinations.

Maternal Effect on Birth Weight in South Devon × Dexter Cattle Crosses

In reciprocal crosses between the Shire horse and Shetland pony, representing respectively extremes in large and small breeds, Walton and Hammond[1] demonstrated that the size of the offspring at birth and the placental weight are directly proportional to the size of the dam, and not simply intermediate between the sizes of the parent breeds. Hammond[2] postulated that the limitation of size in the cross-bred fœtus carried in the small mother is possibly brought about by a higher rate of metabolism of maternal tissues, as compared with a lower rate in the large breed. Otherwise, it was argued, special growth substances of maternal origin may be involved.

This approach to the study of factors controlling birth-weight has been followed up with various other types of mammals[3-5]; but the conclusive results obtained from the equine crosses were not achieved. It seems, therefore, that certain factors are responsible for the manifestation of a decided maternal influence, of which the length of gestation and the extent of the differences between the two parent breeds are perhaps the most important. In multiparous animals, furthermore, the maternal influence may be obscured by variations in litter size.

Though in cattle it is not possible to obtain breed differences as great as those available in the horse, we possess an animal with a long gestation period which should promote expression of a maternal effect, if present at all. Observations made during cross-breeding experiments between Holstein-Friesian and Jersey cattle at Beltsville, United States[6], however, revealed no significant differences between either of the reciprocal cross-bred offspring, or the mean of the birth-weight averages for the parent breeds. On the other hand, results of experiments in progress in South Africa[7], where Afrikaner (cows averaging 1,002 lb.) and N'guni (cows averaging 740 lb.) cattle are reciprocally crossed, provide at least some evidence of such an influence.

To gain further information on this subject in the bovine, three South Devon heifers were inseminated with deep-frozen Dexter semen, and three Dexter females similarly with semen from a South Devon bull. The difference in size between these two breeds can be judged from the illustrations, reproduced to scale, shown in Fig. 1 (*a*). Following conception, the animals received routine farm treatment, but were brought under shelter a few days prior to calving to make possible close observation. As soon as the calves were sufficiently dry after birth, weights and body measurements were recorded, while photographs were taken within twenty-four hours post-partum. The results obtained are summarized in the accompanying table; differences in size between the reciprocal crossbred calves at birth are illustrated by the scale photographs shown in Fig. 1 (*b*).

	Calves out of: South Devon dams	Dexter dams	Difference
No of observations	3	3	—
Age of dams at calving (months)	35·7	42·0	6·3
Gestation period (days)	290·3	278·0	12·3
Weight of dams, pre-partum (lb.)	1158·7	614·0	544·7
Weight of dams, post-partum (lb.)	1031·7	535·3	496·4
Weight lost (lb.)	127·0	78·7	48·3
Weight of calves at birth (lb.)	72·0	57·5	14·5
Weight of placenta (lb.)*	10·6	3·2	7·4

* Two observations only for each group

The South Devons, all three maiden heifers, consisted of a fairly homogeneous group regarding both size and breeding, and calved at much the same age. Though also closely related, only two of the Dexter females were first calvers, the third being an older cow with two previous pregnancies. Differences in age within the latter group also accounted for a larger variation in weight. The mothers were all weighed within a day or two before calving, as soon as signs of parturition became apparent. The post-partum weight was recorded within forty-eight hours following calving. This latter figure, in particular, serves as an indication of differences in size between the two parent breeds, namely, the larger breed was nearly twice the size of the smaller.

The mean birth-weight for the calves out of South Devon mothers truly reflects the range encountered. Considering 94·5 lb. as a reliable birth-weight for pure-bred South Devon calves (out of first-calf mothers[8]), it is clear that the size of the cross-

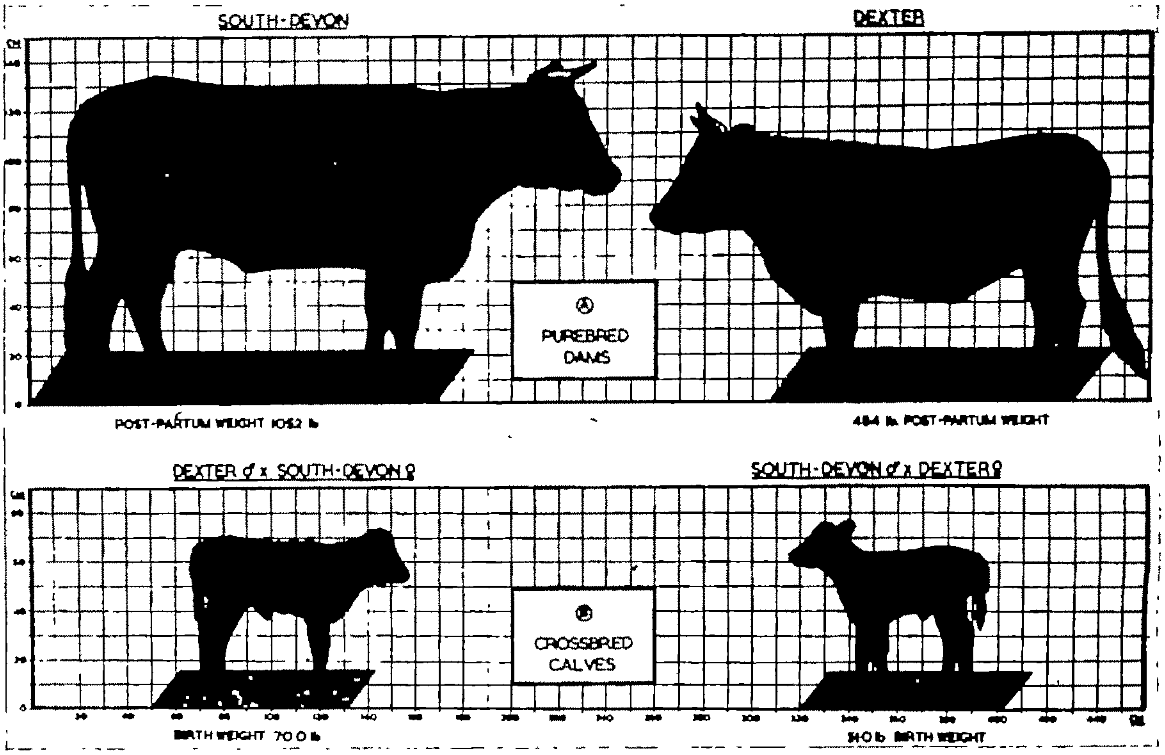

Fig 1

bred offspring, though failing to attain the pure-bred weight, was favourably influenced by the larger uterine environment. The rather prolonged gestation, compared with that of their reciprocal crosses, also indicates that there was a decided effort to reach maximum size at birth, especially in view of the fact that parturition normally occurs at a time when the fœtus approaches a size characteristic of the species and is still able to pass through the genital passage.

The cross-bred calves out of Dexter mothers were larger (57·5 lb.) on an average than the Dexter breed mean of 52·3 lb.; but the effect of restricted uterine space nevertheless is apparent. The average value, though probably a true reflexion, is, however, composed of a rather wide variation ranging from 40·5 to 81·0 lb. The smaller calf was produced by a small (352 lb.) two-year-old heifer, in fact too small to deliver a calf even of that size. Though the small dam severely limited overall size of the fœtus, the early maturing fœtal head had much the same proportions as that of a calf 12–15 lb. larger, which made a normal parturition impossible. The large birth-weight of the latter individual may be explained by the more advanced age (6 yr.) and greater size (770 lb.) of the mother. Furthermore, the mother had the advantage of abundant early summer grazing during late pregnancy which was not available to any of the other cows included in the study.

Expressing the birth-weight of the calf as a percentage of the weight lost during parturition, striking differences are revealed. Calves out of South Devon dams constituted 56·7 per cent of the total loss, compared with 73·1 per cent for calves out of Dexter dams. Hence, in the event of a restricted uterine environment, the fœtus receives preference over development of accessory tissues and fluids, rather similar to the effect of a low nutritional plane[9]. This fact was substantiated by the placental weights. Not only is the placenta smaller in absolute measure in the case of the small calf, but it is also relatively smaller. The placenta expressed as a percentage of the birth-weight equals 14·5 and 7·1 per cent respectively for the large and small reciprocal crosses.

When mating a large bull to a small cow, provided the mother is normally developed for her age, the results indicate that the smaller maternal environment should restrict fœtal size sufficiently for parturition to be possible. On the other hand, in the case of an inter-breed crossing in which the mother is the larger parent, she will exercise a beneficial influence on the offspring, at least so far as size at birth is concerned. It is hoped that the investigation may be continued to study post-natal growth to determine whether this advantage is still manifested during later life.

Our thanks are due to Mr. L. E. Rowson, Agricultural Research Council Unit of Reproduction, for performing the inseminations and for veterinary attention, and also to Mr. G. Pluck and staff members of the Animal Research Station, Cambridge, for assistance with the experimental animals.

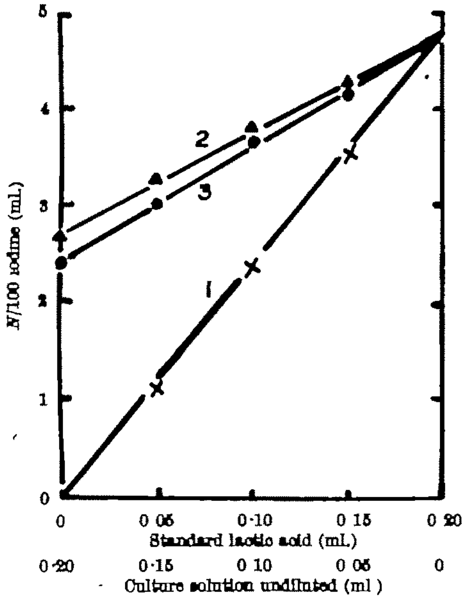
Determination of Lactic Acid in Cultures of Lactobacilli

THE technique of Barker and Summerson[1] for the determination of lactic acid in blood has been successfully applied to the determination of this acid in silage[2,3] and in milk[4]. During the course of work which is being carried out jointly in these laboratories and in those of the Department of Bacteriology, Edinburgh and East of Scotland College of Agriculture, on the formation of lactic acid and volatile fatty acids in cultures of lactobacilli, it became clear that the results obtained by the above technique were unsatisfactory. For example, extremely high 'blanks' were given by the culture medium itself, and it was found impossible to obtain replicate results with samples of the same cultures. Various dilutions of the uninoculated medium were tried and it was found that even at high dilution substantial development of colour occurred. This was originally thought to be due to the high glucose content of the medium (5 per cent w/v); but, again at high dilution, this seemed unlikely. The possible answer may lie in factors involved in the yeast extract incorporated to the extent of 0·5 per cent w/v in the medium.

Recourse was made to the method of Long[5], which has been found to be wholly satisfactory for the present purpose. The method as used here is as described in the original paper, except that 0·1–0·2 ml. of culture fluid is introduced into the thistle funnel of the apparatus and is washed into the distillation tube with 4 ml. of water. Where very large amounts of lactic acid are present, it is advisable to dilute an aliquot of the culture by 10 and to use 0·2 ml. of the diluted fraction. From recovery experiments (Fig. 1) it would appear that material containing considerably larger quantities of lactic acid than those suggested by Long may be successfully handled. The general run of all experiments has indicated a recovery of lactic acid varying between the limits of 95·5 and 103 per cent.



1 ml. N/100 iodine = 0·45 mgm. lactic acid

Fig. 1. Recovery of lactic acid: (1) from 0–0 20 ml. of standard (1·20 gm. of acidified lithium lactate/100 ml.); (2) from mixtures of lactate standard and added amounts of culture of lactobacillus (homofermentative strain at 30° for 12 hr.); (3) as in (2), using a heterofermentative strain grown at 45° for 72 hr

A full account of the results obtained in the study of acid formation in cultures of lactobacilli will be published elsewhere.

Interference and Cell Protection by Poliomyelitis Virus in Tissue Culture

RECIPROCAL interference between strains of the three recognized types of poliomyelitis virus has been reported by Ledinko[1], using roller-tube cultures of monkey testicular tissue. In her experiments, both the 'interfering' and the 'excluded' virus were fully cytopathogenic, and there was no suggestion of any mutual inhibition of their degenerative effects on the cells. Prevention of growth of the second virus, as shown by titration in the presence of type-specific antiserum against the first, was apparently the result of pre-emptive infection and subsequent destruction of susceptible cells by the first virus. The purpose of this communication is to describe a further example of interference among poliomyelitis viruses, in which a more direct recognition of the effect was made possible by the peculiar cytopathogenic behaviour of the interfering virus.

Roller-tube cultures of rhesus monkey kidney were used. Pieces of minced tissue, about 1 mm. in diameter, were stuck to the glass with a thin plasma clot and grown in 2 ml. of a medium consisting of the synthetic mixture 199 [2] with 5 per cent of heated horse serum and 1 per cent of chick embryo extract. After eight days, most of the explants had produced an epithelial-cell outgrowth of about 5 mm. radius. At this time the medium was replaced by 2 ml. of mixture 199 and the cultures were ready for infection.

During the second and third passage in such cultures of the newborn mouse-'adapted' MEF_1 strain of Type 2 poliomyelitis virus[3], a characteristic picture was seen by the fifth day after inoculation: most of the affected cells were already in advanced decay and coming off the glass; yet around each explant there remained an island—1–2 mm. in radius—of healthy looking cells. The edge of these islands was quite sharply defined and picked out by a 'tide-mark' of degenerating cells and cell debris, as shown in the accompanying photograph. Slowly, the more outlying cells became increasingly granular, and degeneration progressed towards the explant. Finally, between two and three weeks after infection of the culture, the explant disintegrated and its dependent sheet broke up into individual cells, which before long were destroyed.

Cultures infected five days earlier with approximately a hundred cytopathogenic doses (TCD_{50}) of third-kidney-passage MEF_1 virus were re-inoculated, after renewal of the medium, with 100 TCD_{50} of either Mahoney (Type 1), *Y-SK*, *MIN* (both Type 2) or Saukett (Type 3) strains of poliomyelitis virus, all producing rapid and complete degeneration of outgrowth and explant in cultures of monkey kidney. A cytopathogenic strain of Coxsackie virus was also

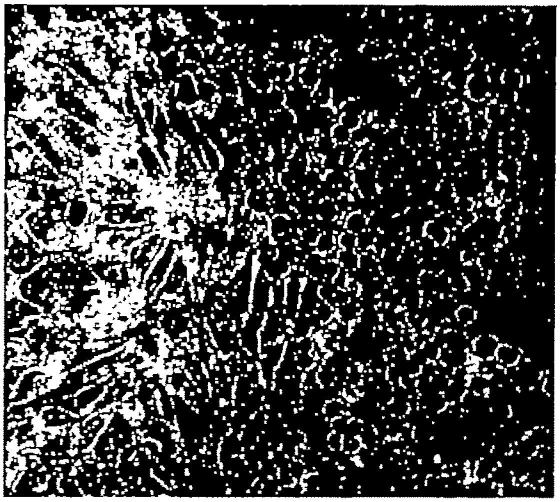

Fig. 1. Culture of monkey kidney five days after infection with MEF_1 virus. (The ocular was × 10, the objective × 5.) The explant is out of the picture to the left. Photograph taken by Mr. W. Clifford

tested. Similar cultures, but uninfected with MEF_1 virus, were inoculated as controls.

Within the first two days after superinfection, no obvious change was noted in the cell-islands, whereas the control cultures had by then almost completely degenerated. Thereafter, marginal degeneration of the islands began again and proceeded as in the MEF_1 controls, or more rapidly. It was clear, however, that those cells which had weathered the initial MEF_1 attack had been temporarily spared from the destructive action of the other four strains of poliomyelitis virus and the strain of Coxsackie virus.

Sabin, Winsser and Hennessen[4] reported that large doses of MEF_1 virus of the 134th baby-mouse passage produced no degeneration in cultures of cynomolgus monkey kidney, but that several blind passages yielded cytopathogenic virus. Lines of low or absent, and of high, cytopathogenicity have since been separated (Sabin, personal communication) and it has been found possible to titrate the first virus thanks to its blocking of the degeneration produced by the second.

In previously reported examples of interference between animal viruses in tissue culture, the demonstration of an interfering effect has depended on subtitrations of the second virus either in animals or in further tissue cultures. The observations of Sabin and his colleagues and those now reported are concerned with the direct, microscopic detection of virus interference, as seen in the exposed cells. To these cells the first virus, having forestalled the second, has given a definite, if transient, protection by virtue of its presence and activity at the surface or in the interior of the cell, or by some other means unknown.

Biogenesis of Hyoscyamine

THE biogenetic origin of the tropane bases has recently been the subject of some discussion[1,2], Mortimer[1] suggesting that the tropane skeleton may be derived from the breakdown products of tryptophan metabolism. This novel idea is contrary to the accepted hypothesis that a base such as tropine is produced *in vivo* by reactions analogous to the *in vitro* synthesis[3] of tropinone from succindialdehyde, methylamine and acetone. The succindialdehyde is considered to be a metabolite of ornithine, and James[4] showed that significant increases in the amount of hyoscyamine in *Atropa belladonna* occurred following the feeding of arginine or ornithine.

We have tested this hypothesis by feeding radioactive ornithine to mature *Datura stramonium* plants which produce hyoscyamine and hyoscine. [α-^{14}C]-Ornithine hydrochloride with an activity of $4 \cdot 8 \times 10^{7}$ disintegrations/min./m*M* was administered to the plants by addition to the aerated nutrient solution in which the roots were growing. After a week, almost all the activity had disappeared from the nutrient solution and was translocated throughout the plant. The crude alkaloids were obtained from the dried plants by standard methods[5]. Paper chromatography of the alkaloids showed radioactivity to be present in the spot corresponding to hyoscyamine, but little or none to be present in that corresponding to hyoscine. The alkaloids were separated on a 'Celite' column[6] yielding pure hyoscyamine aurichloride with a specific activity of $1 \cdot 08 \times 10^{6}$ disintegrations/min./m*M*. The hyoscine obtained from the column was inactive. The radioactive hyoscyamine was degraded to locate the positions of activity. Alkaline hydrolysis gave active tropine and inactive tropic acid. Oxidation of the tropine with a mixture of chromic and sulphuric acid[7,8] gave N-methyl-succinimide, which had the same specific activity as the hyoscyamine. Reaction of the imide with phenyl magnesium bromide according to the procedure of Lukeš and Prelog[9] gave 1-methyl-2,5-diphenylpyrrole, which was oxidized with aqueous potassium permanganate to give a mixture of inactive oxalic acid (from the β-carbons of the pyrrole) and benzoic acid which had a specific activity half that of the hyoscyamine. This indicated that all the activity in the hyoscyamine was present in the bridge-head carbons (1 and 5) of the tropine. It thus follows that ornithine is indeed the precursor of the pyrrolidine ring of tropine and renders very improbable the speculations of Mortimer[1].

Previous work in these laboratories[5] has shown that [1,4-^{14}C]-putrescine when fed to *D. stramonium* at a stage of growth corresponding to that in the present experiments did not give rise to radioactive hyoscyamine. Putrescine is thus apparently ruled out as an intermediate between ornithine and tropine, and its presence in various plants would seem to represent an alternative pathway of ornithine metabolism. The work of James[10] with enzyme extracts of belladonna indicates that α-keto δ-amino-valeric acid is a probable intermediate in the synthesis of tropine, the δ-nitrogen of this acid becoming the tropine nitrogen. Thus the present experiment with [α-^{14}C]-ornithine would be expected to yield tropine labelled on only one of the bridge-head carbons; however, the symmetry of the molecule renders it impossible to differentiate between the two bridge-head carbons by chemical methods.

Since no activity was found in the hyoscine, it would seem that tropine is not a precursor of scopine. It is possible that it is produced from a hypothetical hydroxy-ornithine which could conceivably be obtained from hydroxyproline.

Electrophoretic Migration of Contents of Intact Liver Nuclei

During attempts to separate rat liver nuclei from fragments of cell membrane by electrophoresis, we have observed movement of the nuclear contents, the nuclei remaining stationary.

The nuclei were obtained by homogenization of fresh rat liver in a glass tube with stainless steel non-rotating conical plunger. The suspending fluid was either 0·29 *M* sucrose or 3·3 *M* glycerol, with the addition of 0·01 *M* sodium chloride or of 0·001 *M* calcium chloride; in the latter case the free calcium concentration was theoretically maintained at this value by the addition of 0·0025 *M* dipotassium salt and 0·0075 *M* potassium calcium salt of nitrilotriacetic acid. The *p*H was adjusted to 6·9, or, in a few cases, to 8·0, with 0·003 *M* barbitone buffer. The nuclei were partially freed of whole cells and mitochondria by centrifugation, and then observed in a modified Abramson[1] micro-electrophoresis cell, under a phase-contrast microscope.

When potential gradients of 10 V./cm. and above were applied, the nuclei remained stationary; but the nuclear contents, including the nucleoli, moved to the side of the nuclei towards the anode (Fig. 1). This produced a half-dark, half-light appearance of the nucleus, called for convenience an 'eclipse'. If after a few seconds the current was switched off, the contents flowed back to their original position, and the normal appearance was restored. However, after several repetitions of this procedure with higher potential gradients (50 V./cm.) the 'eclipses' became irreversible and persisted on switching off the current; this irreversibility was sometimes accompanied by shrinkage and appearance of granularity in the nuclei. The 'eclipses' were seen at *p*H 6·9 and 8·0, and at both *p*H's and in all the media used red cells and bacteria moved immediately and rapidly towards the anode and cathode respectively, and stopped directly the current was switched off.

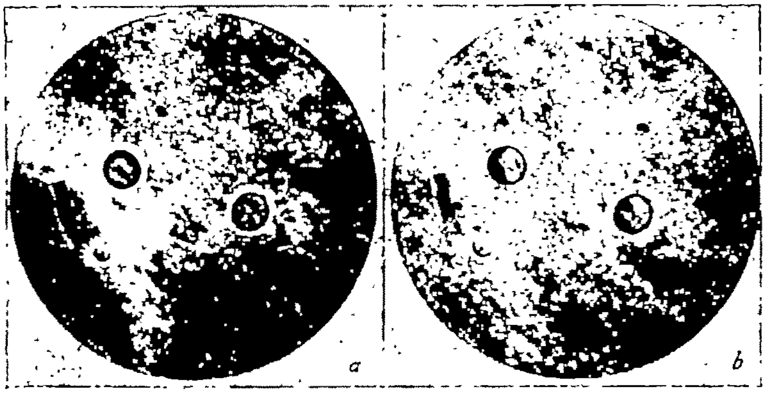

Fig. 1. (*a*) Liver nuclei. (*b*) The same under potential gradient of 38 V./cm. Note anodic migration of nuclear contents including nucleoli. The anode is on the left

An attempt was made to increase the net negative charge on the nucleus as a whole, and so to make it move, by addition of potassium polymethacrylate to a final concentration of 0·0002 *M* (about a fifth of the concentration required to release nucleic acid from combination with histone). There was some suggestion that in this medium 'eclipses' were formed less readily, and that the nuclei moved slowly towards the anode. However, the results were not clear-cut.

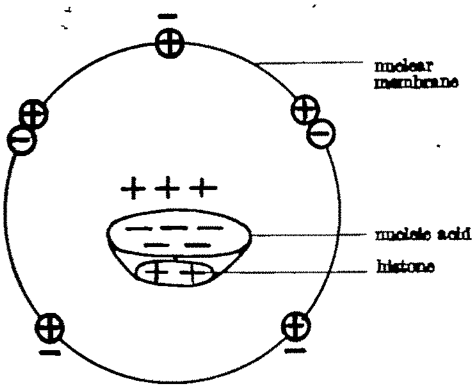

Fig. 2. Diagrammatic interpretation of electrophoretic behaviour of nucleus

An interpretation of the 'eclipse' phenomenon is expressed crudely in Fig. 2. The plus and minus signs represent ions, of which the encircled ones are imprisoned either inside the nucleus or on the nuclear membrane, whereas the unencircled ones can move freely through the nucleus and its membrane. The imprisoned ions are shown predominantly negative within the nucleus and positive on the membrane, the totals being equal, in order to explain the non-migration of the whole nucleus and the anodic migration of the contents. The net negativity of the contents could be due to a slight predominance of nucleic acid over histone in the nucleoprotein, whereas the unused histone might perhaps be responsible for the net positivity of the membrane.

The above experiment shows that the contents of reasonably undamaged resting nuclei have a high electrophoretic mobility, and is of interest in connexion with the question whether movement of chromosomes during anaphase can be electrophoretic. The potential difference maintained by us between opposite poles of the nucleus was of the order of 10 mV., and caused the contents to pile up against the membrane in a few seconds. Chromosome migration is slower than this, and the potential difference needed for it should be easily maintainable biologically.

Participation of Pyridoxal Phosphate in the Enzymic Synthesis of Serine

Evidence that pyridoxal phosphate is involved in the synthesis of serine by micro-organisms has been provided by Lascelles and Woods[1], who found that incorporation of pyridoxal phosphate in the medium stimulated serine synthesis by washed cells of *Streptococcus faecalis* R. and enabled *Leuconostoc mesenteroides* to grow in the presence of glycine and a CO_2-rich atmosphere instead of serine. Participation of pyridoxal phosphate in serine synthesis in chickens was suggested by the observation that liver extracts from pyridoxine-deficient chickens showed a reduced ability to incorporate [^{14}C]formate into the β-position of serine[2]; but hitherto attempts to demonstrate a direct activation by pyridoxal phosphate of serine synthesis by liver extracts have been unsuccessful[3].

The role of pyridoxal phosphate in serine synthesis has been further studied with an enzyme preparation which was extracted from acetone-dried rabbit liver powder and partially purified by heat treatment and ammonium sulphate fractionation at pH 7·5. The enzyme was incubated with glycine, formaldehyde, tetrahydropteroyl glutamic acid (tetrahydroPGA) and bicarbonate buffer, pH 7·2, at 37° for 1 hr. Serine was determined by manometric estimation of the carbon dioxide produced by periodate oxidation. A control in which tetrahydroPGA was omitted provided an adequate correction for small amounts of carbon dioxide produced by periodate oxidation of material other than serine.

Addition of pyridoxal phosphate to the otherwise complete system appreciably increased the rate of serine synthesis, increments of more than 100 per cent being sometimes obtained in the presence of 5×10^{-4} M pyridoxal phosphate. Although added pyridoxal phosphate consistently increased serine synthesis by these enzyme preparations, they nevertheless exhibited considerable activity in the absence of added pyridoxal phosphate. Prolonged dialysis, even after subjecting the enzyme to high salt concentrations at temperatures up to 60°, did not significantly reduce the activity in absence of added pyridoxal phosphate, provided the pH was kept within the limits 5·0–7·5. After the enzyme had been incubated for 30 min. at pH 8·6 and 37°, however, it was almost inactive for serine synthesis. An enzyme preparation so treated could be largely reactivated for serine synthesis by incubation with pyridoxal phosphate at pH 7·2 and at 37° prior to addition of substrates. The degree of reactivation increased as the period of incubation of the enzyme with pyridoxal phosphate was increased up to 2 hr. Under these conditions serine synthesis with the pyridoxal phosphate-reactivated enzyme was up to one hundred times greater than that with the inactivated enzyme.

Similar though less striking effects of pyridoxal phosphate on serine breakdown were also observed, both with normal and inactivated enzyme preparations. The reaction was in this case followed by measuring formaldehyde produced by the enzyme from DL-serine[4].

A more detailed report of this work will be published elsewhere.

I wish to thank Prof. A. H. Ennor for helpful advice and Mr. T. Curtis for technical assistance. I am indebted to Dr. A. L. Morrison of Roche Products for a gift of crystalline pyridoxal phosphate.

The Precursor of 2-Carboxy-Pyrrole in Mucoproteins

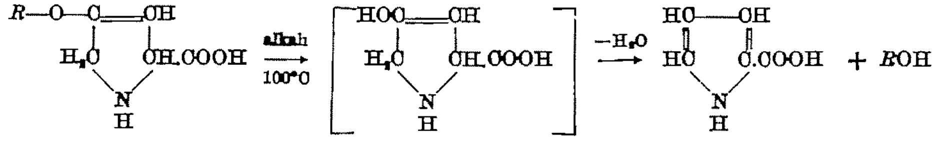
We have previously reported[1] the isolation of a pyrrole derivative from the alkaline hydrolysate of bovine submaxillary gland mucoprotein and its identification as 2-carboxy-pyrrole (III). On reduction it yielded 2-carboxy-pyrrolidine (proline), chromatographically it showed the same behaviour as synthetic III, and it gave in the cold a purple colour with Ehrlich's reagent. Recently, the ultra-violet absorption spectra of both the substance prepared from mucoprotein and synthetic III were found to be identical.

The presence of about 4 per cent of the Ehrlich-reacting substance in the mucoprotein together with the high molecular extinction coefficient of III ($\epsilon_{max.}$ 256 mμ = 11,118 in phosphate buffer pH 7·0, ionic strength 0·05) prompted us to carry out a spectroscopical analysis of the untreated mucoprotein. Contrary to expectation, no peak at 256 mμ was exhibited, though admixture of III corresponding to 2·6 per cent of the dry weight of the mucoprotein present gave rise to an easily detectable peak at 256 mμ.

Like many other mucoproteins, the bovine submaxillary gland mucoprotein inhibits influenza virus hæmagglutination. Interaction between inhibitory mucoproteins and purified influenza virus (or the receptor-destroying enzyme of *Vibrio cholerae*) was shown[2] to result in the liberation of a dialysable compound consisting of a non-amino sugar and a nitrogenous component. The compound decomposed on treatment with dilute mineral acid. It coupled with p-dimethylaminobenzaldehyde to give a purple colour even after prolonged treatment with alkali, though alkali treatment was not necessary for colour formation[3]. These properties strongly suggested the identity of the colour-producing component with III which we had isolated previously from the substrate for the viral enzyme or for receptor-destroying enzyme. When the compound split off from the purified bovine submaxillary gland mucoprotein by action of receptor-destroying enzyme was analysed spectroscopically, no indication for the presence of III was obtained. Upon treatment of the split product with $0 \cdot 1 N$ sodium carbonate for 10 min. at 100° C., however, an ultra-violet absorption spectrum became apparent practically coinciding with that of synthetic III. Paper partition chromatography of the alkali-treated split product confirmed the presence of III.

It would thus appear that mucoproteins contain an amino-acid which on very mild alkali treatment is readily transformed into III. The possibility that one of the following compounds, glutamine, 2-carboxy-pyrrolidone, 2-carboxy-pyrrolidine, 4-hydroxy-2-carboxy-pyrrolidine (hydroxy-proline), N-acetyl-glucosamine, may be the precursor was examined, but in each case with negative result.

We conclude from these data that the most probable structure of the precursor of III in the biological material tested is 4-hydroxy-2-carboxy-pyrroline (II), stabilized by the engagement of its enolic hydroxyl group in a glycosidic linkage apparently with a pentose (I). The glycosides of enols easily yield to alkali hydrolysis; therefore, mild alkali treatment of I will release II which, being unstable, instantaneously becomes stabilized to III by a shift of the double bond and loss of 1 mol. H_2O.



(I) (II) (III)

It seems probable that neuraminic acid ($C_{16}H_{13}O_8N$) prepared by Klenk[4] as its methoxy derivative from bovine submaxillary gland mucin is identical with I ($C_{10}H_{15}O_7N.2H_2O$), and that sialic acid[5] and *lactaminsaure*[6] are closely related to I. On the other hand, Hiyama's[7] claim that a crop of 2-carboxy-pyrrole crystals may be obtained by treating the mucoprotein primarily with 10 per cent potassium hydroxide at 100° C. for 10 hr. could not be substantiated in our laboratory, nor is his interpretation of the origin of III consistent with the above observations.

Details of these results will be published elsewhere.

Effect of Ephedrine on Dark Vision

THE effect of drugs on night vision and dark adaptation is a problem of both theoretical and practical importance which has already received a good deal of attention, particularly during the Second World War. Of the various drugs the effects of which have been investigated systematically, ephedrine has apparently featured in only one experiment, namely, that of Rose and Schmidt[1]. These authors report no significant effect on dark adaptation. Further studies on the influence of ephedrine and other sympathicomimetic drugs are particularly desirable in view of the claims of Babskii[2], Kekcheyev[3] and their associates that the sympathetic nervous system exerts an 'adaptive influence' on the visual analyser, and of recent research at the Institute of Psychiatry which suggests that the impaired dark vision of neurotic patients may be due to sympathetic over-activity. To obtain further information on this point, an experiment was undertaken with four subjects using a test of night visual ability which had previously been shown in several studies to differentiate normal from neurotic groups.

This test involves recognition of the position of a triangular test object against a circular, uniformly illuminated, field subtending about four degrees. Threshold judgments, expressed in grades of brightness, are obtained at four times—three, five, seven and ten minutes—after dark adaptation begins. The criterion of 'success' at a particular level of brightness is two consecutive correct judgments. Although the test makes demands on the subject's dark adaptation, it is more accurately termed a test of visual ability under conditions of low illumination, for it involves factors other than mere light sensitivity.

A four-by-four Latin square design was employed for the experiment, each subject receiving one of four 'treatments' on each of four consecutive days. Treatments were as follows: (1) control; (2) drug (dark vision being tested one hour after the subject had received the drug); (3) drug 1 (test administered one and a half hours after receiving drug); (4) placebo. Ephedrine was given orally, each subject receiving 1 gr.

The resulting table of dark-vision grades for three, five, seven and ten minutes was submitted to analysis of variance to determine the relative effect of the various components, individuals, days and treatments. Results of this analysis show quite clearly that the drug treatment had no significant effect on dark-vision grades. The analysis of variance table for threshold measures at three minutes is reproduced herewith; tables for five, seven and ten minutes are essentially similar in general form. The mean dark-vision grade for control and placebo treatments was 27·65 compared with a mean of 28·34 for the two

Source of variance	Sums of squares	Degrees of freedom	Mean squares
Individuals	75·5	3	25·16
Days	5·5	3	1·83
Treatments	3·0	3	1·00
Residual	11·0	6	1·83
Total	95·0	15	

drug treatments. Day-to-day variation within individuals was not significant.

Taken in conjunction with the results of Rose and Schmidt's experiments on light thresholds, these findings cast[1] some doubt upon the validity of any general hypothesis concerning the positive or negative effect of sympathetic activity on dark vision. They do not, however, necessarily invalidate more specific types of hypothesis. Thus, it is conceivable that ephedrine would exert a significant effect on visual ability during the latter part of the adaptation period. Indeed, closer examination of Rose and Schmidt's results suggests a definite impairment of sensitivity from about 15–40 min. after the beginning of dark adaptation, even though there is no appreciable effect before that time. Although the deviations were not statistically significant according to the tests applied, the consistent trend during the 15–40 min. period points to the need for a repetition of their work and an extension of the present study to include the latter part of the adaptation curve. It is hoped to undertake these further studies as part of a general programme of research on visual and ocular processes in psychiatric patients.

I am indebted to Mr. A. S. C. Ehrenberg, Dr. J. G. Thorpe and Dr. D. S. Troughton for their helpful discussion when the experiment was planned. To Mr. Ehrenberg I am also grateful for the Latin square design.

Maintenance *in vitro* of *Fasciola hepatica*

A necessary preliminary to a study of the physiology of helminths is their maintenance *in vitro*, a rare accomplishment. Some nematodes and a few cestodes have been maintained for some time with moderate success, and this is also true for certain small trematodes[1], but not for *Fasciola hepatica*. This common liver fluke of the sheep has so far lived *in vitro* only for short periods of about 60 hr. and never more than about three days. These were the best results of experiments[2] in which worms were taken from the livers of cattle or sheep which had been dead for 1–6 hr. and transported from the abattoir to the laboratory in cold bile. Batches of seven to nine worms were then immersed in 500 c.c. of various saline solutions and incubated at 37° C., solutions being changed after 16 hr. and after a further 24 hr. In my opinion, an over-elaborate series of experiments failed because the medium (which contained sodium borate) was unsuitable and the trematodes often moribund at the outset. "Many flukes," we are informed, "never moved in the laboratory except on strong stimulation", and results were collected on the basis of 50 per cent survival. More satisfactory methods of culture will serve to keep worms alive in a state of active movement, and such worms will retain the reddish colour and fleshy appearance which is normal to them.

My own experiments have convinced me that *Fasciola hepatica* will live in Stephenson's 'saline III' for about two days; but that at the end of this period they are in a dying condition. No better results are obtained when any one of several other salines are used as media; but Hédon–Fleig solution has given excellent results. This is a buffered, borate-free medium with the following composition: sodium chloride, 7·0 gm.; potassium chloride, 0·3 gm.; calcium chloride, 0·1 gm.; sodium bicarbonate, 1·5 gm.; disodium hydrogen phosphate, 0·5 gm.; magnesium sulphate, 0·3 gm.; glucose, 1·0 gm.; distilled water, 1,000 c.c. This medium is "very useful for any work on living cells of terrestrial or fresh water invertebrates"[3]. It has been used once before[4] for the culture of a trematode—*Aspidogaster conchicola*, a parasite of freshwater mussels of the genera *Anodonta* and *Unio*; but in this instance it proved to be inferior as a medium to mussel blood or even a crude mixture of the body liquids and the liquid abstracted from the viscera and mantle cavities of the hosts. If we believe that a certain close degree of compatibility exists between the tissues of trematodes and those of molluscs (in which larval trematodes develop), this saline medium is a logical choice, because it serves well for the culture of molluscan tissues.

Be this as it may, Hédon–Fleig solution is far superior to Stephenson's 'saline III' as a medium for *Fasciola hepatica*. Many preliminary experiments of mine have proved that the worms will continue to live in this liquid for more than three days and sometimes for five to six days without loss of movement or natural coloration. Clean methods were used in these experiments, and solutions were changed several times each day; but no attempt was made to obtain sterile cultures. The results have been confirmed by a pupil working under my direction, and a technique has been developed which avoids the contamination of the cultures with certain airborne bacteria which exert a lethal effect on the worms after three or more days, no matter how often solutions are changed.

This technique is briefly as follows. Hédon–Fleig solution is passed through a Gallenkamp filter using a 6 cm. Ford 'Sterimat' (grade *SB*) and a number of 25 c.c. portions are set up in sterile 3 in. × 1 in. tubes, plugged with cotton-wool and set in a water bath until required. Warm livers are brought to the laboratory in an insulated container. The surface of each liver is cleansed by swabs soaked in absolute alcohol and the liver is then placed in a small, 'Dettol'-sprayed chamber for dissection, which is carried out by means of sterile instruments. The extracted worms are placed separately in the portions of medium, which also contains a droplet of phenol red to indicate alkalinity. The tubed worms are then incubated at 37° C., with changes into fresh sterile medium as desired.

By this simple method it is possible to maintain *Fasciola hepatica* more or less normal in appearance and in a state of active movement for twelve days. So far, the worms have been killed by fixation at the end of this period, and there is a good prospect of keeping them in this state for fourteen days or longer. (Since this note was written, three isolated worms have been maintained in an active state for fourteen, fifteen and sixteen days respectively.) Moreover, it is now certain that worms can be obtained from excised livers of sheep in a sterile condition. Some failures are inevitable, but they are rare; in general, cultures remain sterile throughout. Whereas formerly[2] the conclusions drawn from physiological experiments with liver flukes maintained *in vitro* for only three days have been far from convincing, because for most of this period the worms were in a dying condition, the prospect is now much more satisfactory, because worms are often more lively after they have been maintained *in vitro* for more than a week than they were on the first day after their removal from the liver. From a nutritional point of view the medium used is very imperfect; but its enrichment holds further promise of extending the period of survival *in vitro* of *Fasciola hepatica*, and providing a sound basis for physiological experiments.

Seasonal Regulation in British Dragonflies

It has long been recognized that the reproductive stages of different species of dragonflies tend to be restricted in incidence, each being characteristic of a given season. During the period 1950–53, the life-histories of several British species were studied with the view of determining the principal ecological factors responsible for their seasonal regulation.

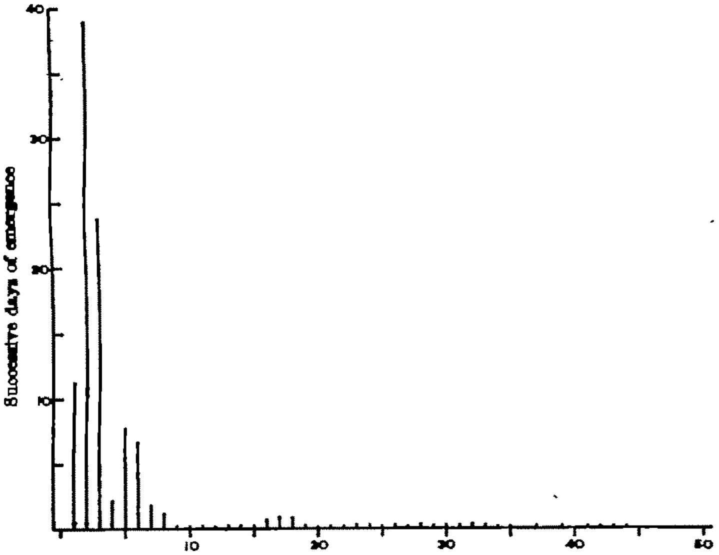

Fig. 1. Time-frequency distribution of adult emergences in a population of *Anax imperator* during 1953. Emergence began on May 25 and finished on July 7

In the Emperor dragonfly, *Anax imperator* Leach, it was found that, although larval populations showed a wide measure of temporal variation, yet emergence was restricted regularly to a period of about forty-five days each year, lying between mid-May and mid-July. The first fourteen days of adult life were spent away from water; after this, when sexually mature, adults returned to the aquatic habitat for reproduction. Oviposition extended from late June to early September. Adults did not survive the summer. The eggs hatched in about twenty-four days and larvæ were half-grown (c. 24 mm., instar 11) by October, after which low temperature prevented further development. In the following April growth was resumed, and the final larval instar (c. 50 mm., instar 15) was entered in August, approximately one year after hatching of the eggs. A diapause occurred in the final instar, and morphogenesis was suspended until diapause development had been completed in the autumn. This did not take place until the temperature had fallen below the threshold permitting metamorphosis. In this way it was assured that final instar larvæ embarked upon metamorphosis simultaneously, as soon as conditions became favourable in the spring. Thus, the temporal variation accumulated during the long period of larval development was effectively erased in the final instar. Eclosion, which directly succeeded metamorphosis, was closely synchronized, more than 90 per cent of the annual population of adults emerging within the first ten days of the emergence period (Fig. 1).

In this life-history the synchronization of emergence can be seen as a direct consequence of the diapause in the final larval instar. Recognition of this causal relationship means that species with a time-frequency pattern of emergence resembling that of *A. imperator* may be expected to feature diapause in the final instar and vice versa. This expectation has been confirmed in *Pyrrhosoma nymphula* (Sülzer)[1], the only other species of which the emergence curve is known throughout the flying season. Dragonflies typified by these two species have been termed 'spring' species, in contradistinction to 'summer' species in which a diapause, if present, is located elsewhere in the life-history. In summer species the final larval instar is usually entered in the year of emergence and, since growth is uninterrupted at this stage, larval variation finds expression in the emergence curve, which is temporally dispersed. Although not invariably the case, summer species usually emerge later in the year than spring species, since they have at least one extra instar to complete before commencing metamorphosis.

This ecological classification has been found to hold good throughout the British dragonflies, of which approximately half are spring and half are summer species. It corresponds with recognized taxonomic affinities at a generic level but shows departure when families are considered.

It is likely that the principles of this classification apply generally where there is a biological demand for rigorous seasonal regulation, and comparative treatment of other insect groups may throw an interesting light upon the colonization of temperate regions and upon the evolution of different types of life-history.

This work was financed by the Department of Scientific and Industrial Research, and is to be described more fully elsewhere.

Direct Microscopy for Study and Count of Soil Protozoa

It is generally accepted that only direct microscopy is able to give a reliable estimate of the total numbers of micro-organisms present in soil. Suitable direct techniques have been developed for counting the bacteria, fungi[1] and algae[2]. No adequate technique is available for the protozoa. A recently developed culture technique[3] is a considerable improvement, but tends to be selective and is time-consuming in operation.

The direct examination of protozoa in soil has been made difficult by their low numbers and by the lack of a suitable differential staining technique. The following method overcomes these difficulties.

A known amount of 1 : 5 soil : water suspension is spread on a slide and fixed wet with osmic or formalin vapour. After drying, it is stained with erythrosin, washed, and then counterstained with methyl green. The preparation is mounted in immersion oil.

Colloidal particles in the soil appear green, protozoa pink with a purple nucleus. Flagella and cilia are readily visible. Contrast is sufficient to enable effortless counting with a low-power objective lens. The selective influence of cultural methods is eliminated.

The technique is of general use for soil studies. Bacteria, fungi and algae are stained purple and may be picked out quite readily against the green background of soil particles.

The details of this method will be published elsewhere.

The Sorghum Midge Diapause

The sorghum midge, *Contarinia sorghicola* (Coq.), is an important pest of grain sorghums in Queensland, where its incidence and intensity of attack vary considerably from season to season and from early to late crops. Activity commences about two weeks after wet weather and high humidity, and crops flowering at the time may suffer severely. In central Queensland, where the rainy season is concentrated in late January and February, the mid-season crops are often damaged whereas those flowering in March and early April escape the pest. Farther south the wet season is not so well defined, although the peak often coincides with late flowering. In these districts the midge is seldom a pest of early and mid-season crops.

Laboratory experiments have demonstrated that larval diapause is broken and midge will emerge after the infested material is thoroughly wetted and incubated at relative humidities of 94–100 per cent, at temperatures of 25°–30° C. Emergence commences a fortnight after wetting, and may continue for a further four weeks. Under these conditions midge and its parasite, *Eupelmus australiensis* Gir., have emerged in appreciable numbers even from infested grain which had been stored for four years.

These laboratory findings are being correlated experimentally with midge behaviour in the field, and a full account will be published at a later date.

Internal Infection of Tomato Seed by *Didymella lycopersici* Kleb.

Previous studies have indicated the importance of infected seed as a source of the stem and fruit rot disease of tomatoes caused by *Didymella lycopersici* Kleb. Hickman[1] reported 25–34 per cent infection of an outdoor crop grown from seed, a proportion of which was infected. Schoevers[2] demonstrated the presence of mycelium and pycnidia of the fungus on the seed coat and radicle of germinating seed, and Ogilvie[3] observed the fungus on the cotyledons and hypocotyl of tomato seedlings.

These studies were concerned with the location and effect of the fungus after germination had occurred. There appears to be little information, however, on the way in which the seed becomes infected and the location of the fungus on or in the ungerminated seed. Since such information is likely to be of value in determining the best methods of obtaining clean seed, a study has been made of the matter in the course of research now being conducted on the disease.

Sections of naturally infected fruit (var. Stonor's Money-Maker) bearing black lesions at the calyx end approximately ½–1 in. in diameter showed that the fungus had grown down the placenta and invested many of the seeds. Sections of the seeds revealed the presence of numerous hyphæ and pycnidia within the tissue of the funicle and also a more extensive internal invasion of some seeds. In these, the fungus had grown beneath the outer seed coat as far as the distal end of the seed and had formed numerous pycnidia. The main site of fungal growth was within the gaps which form between the layers of the seed coat as it matures. No fungal hyphæ were seen in the embryo. Dried seed from infected fruit also contained hyphæ and pycnidia.

Following these observations on naturally infected material, ripe tomato fruits (var. Radio) were artificially infected at the calyx end with a spore suspension from an isolate of *Didymella* known to be pathogenic to tomato stems. After thirty days, seed

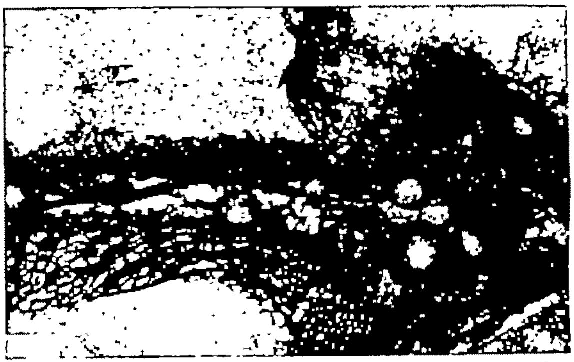

Fig. 1. Section of tomato seed (var. Radio) infected with *Didymella lycopersici* Kleb. showing hyphæ and pycnidia of the fungus in the funicle region and beneath the outer hairy seed coat. × 45

infection similar to that described above for naturally infected fruit was seen (Fig. 1). Isolations were made of the fungus from the inside of the infected seeds, and it was found to be identical with that inserted into the fruit.

Internally infected seed was found to germinate at least as well as comparable healthy seed.

These observations and experimental results indicate that the infection of tomato seed by *Didymella* is not solely due to external contamination by spores but also involves internal fungal invasion.

Crystal Defects in Freshly Worked Surfaces

RECENTLY, it has been suggested[1] that the emission phenomena (Kramer effect) and the blackening of photographic plates (Russell effect) observed with freshly worked or evaporated surfaces of certain metals may be due to the presence of sites of low work function, since photoelectric emission can be observed in the visible range of light.

Using a number of overlapping optical filters of narrow band-width, the photoelectric response of such surfaces has been explored by means of an open-ended Geiger counter, operating in an air–alcohol mixture at 10 cm. mercury, and it has been found that with aluminium (abraded and evaporated) and zinc (abraded) an emission peak is present at a wave-length of 4700 A. Evaporated copper and gold were found to be inactive. From these and other experiments it was concluded that this selective photoelectric effect is found mainly with metals which are known to form 'excess-metal' oxides, such as aluminium, zinc or cadmium, and that the effect is due to the presence of crystal defects in the oxide. It is suggested that the selective photoelectric effect observed, and other associated phenomena, are due to oxygen ion vacancies acting as electron traps. The mode of formation of these imperfections in metal films, evaporated in the presence of traces of oxygen, is considered to be similar to that of 'additive coloration' used for producing *F*-centres in alkali halide crystals. The centres formed in abraded surfaces, on the other hand, may result from the encounter of an ion vacancy pair with a metal atom.

An oxygen ion vacancy is divalent; it would be expected, therefore, that it could accommodate one, two or three electrons. From experiments on the luminescence of zinc oxide, three impurity-levels at 3·1, 2·6 and 1·9 eV. are known to exist[2], and the 2·6-eV. level is probably identical with the impurity level at 2·64 eV. responsible for the selective photoelectric effect at 4700 A. The centres may therefore be identified with oxygen ion vacancies occupied by two electrons.

It appeared of interest to establish whether blackening of photographic plates (Russell effect) could be achieved with deformed ionic materials such as rock salt. Friction tracks were made on crystals of rock salt by sliding a hemispherical steel specimen over the surface. Blackening of photographic plates (Q2 Ilford) only occurred after the deformed part of the surface had been exposed to the action of X-rays. The formation of the image is not due to the action of hydrogen peroxide (Russell effect), as is the case with certain abraded and evaporated metals[3], since the interposition of a sheet of mica did not prevent blackening. It was concluded that the blackening of the photographic plate was due to luminescence centres which were formed during the irradiation of the highly deformed surface layer in the friction track. Fig. 1(*a*) shows micrographs of three tracks on a rock salt crystal made under three different loads and Fig. 1(*b*) shows the record obtained. Apart from the three black bands corresponding to the three friction tracks, a fourth band is strongly evident from a track made in a previous experiment, which had been thought to have been completely removed by washing the crystal with water. The fourth band indicates that deformation during the friction experiment extended to great depth.

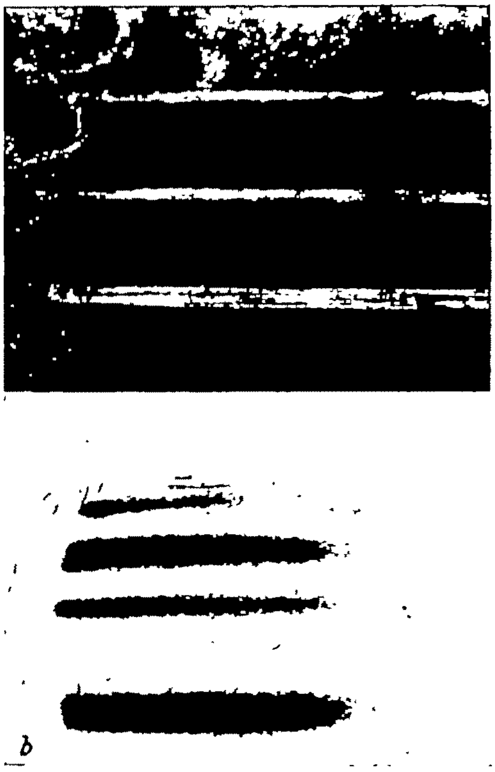

Fig. 1

From the response to photographic plates of various sensitivities, the range of wave-lengths within which the luminescence lies was estimated to be approximately 2000–3000 A., corresponding to a radiative transition of between 4 and 6 eV. This could be explained by a transition of an electron either from the *F'*-band to the valency band, or from the conduction band to an acceptor level of the V-centre type.

Spontaneous Ignition of an Inflammable Gaseous Mixture on Release from Compression

THE 'shock-tube' method of producing one-dimensional shock waves has found many applications in recent years. It was first used by Vieille[1] to study the establishment and propagation of discontinuous waves in columns of air. Payman and Shepherd[2] applied the method—in their 'bursting-diaphragm apparatus'—to examine, by means of schlieren photography, the nature and spread of the discontinuous disturbance in the expansion chamber. Their results[3] linking shock-wave speed and air flow with the initial pressure in the compression chamber fitted accepted theory. The theory of shock tubes has since been more deeply considered, for example, by Hertzberg[4] in the United States, and by Lukasiewicz[5] in Canada. A shock tube has also been used by Perry and Kantrowitz[6] for demonstrating the luminosity caused by an intense shock wave being propagated in air. Recent developments have been directed towards the use of the shock tube for the generation of shock waves of high Mach number, and for this purpose gases of high acoustic speed have been used in the compression end as the driver agent, the high speed and pressure being obtained by exploding inflammable mixtures of low density behind the diaphragm. Hertzberg and Smith[7] describe some anomalous results in such experiments, and it is to offer perhaps an explanation of these that this communication is made.

The underlying purpose of Payman and Shepherd's investigation was to study, in a simple way, the ignition of a gas mixture by a shock wave transmitted through the mixture, with the view of finding if the shock wave from a detonating coal-mining explosive could, *per se*, cause ignition if the explosive were fired in an atmosphere containing methane and air. An account of early experiments with methane – oxygen and with ethylene – oxygen mixtures in the bursting-diaphragm apparatus (made of drawn steel tubing 2·5 cm. in diameter, the mixture being in the expansion chamber, and air in the compression chamber) has already been published[8]. Ignition by the shock disturbance released by the rupture of the diaphragm was obtained over a wide range of oxygen mixtures with each of these two gases. With the most sensitive mixtures, bursting pressures of the order of 50 lb. per sq. in. sufficed to cause ignition. For most of these experiments diaphragms of copper were used; ignition was also caused when 'Cellophane' (and even strong paper) was used and also, with some mixtures, when the disturbance released by the rupture of the diaphragm had to traverse a column of air before reaching the explosive mixture; these experiments showed that ignition was not associated with any frictional or mechanical effect arising during the actual rupture of the diaphragm. The far end of the expansion chamber was fully open, so that pressure-piling effects associated with a closed end did not arise. Indeed, the schlieren photographs showed ignition was caused near to the diaphragm.

Attempts to ignite methane – air mixtures were unsuccessful, even with diaphragms bursting at 1,100 lb. per sq. in.; rather, they were unsuccessful in that a stab of flame observed (through windows in the expansion chamber) near the diaphragm did not develop into an established explosion accompanying the disturbance as it was propagated through the column of mixture. Evidence was collected which suggested that the spread of flame was prevented by an air gap interposed in the column of inflammable mixture by the dissolution of a vortex ring of air (from the compression chamber) travelling initially *through* the column of mixture, this vortex being the pioneering effect released when the diaphragm ruptured, by shearing cleanly around the periphery of the circle exposed to pressure. The formation of the vortex was a purely mechanical effect, and it always occurred. With sensitive or with strongly explosive mixtures, the explosion was readily transmitted across the gap, but this was not so with methane – air mixtures. Thus, the failure to establish flame in the latter mixtures might not have been due, physically, to a deficiency in the 'igniting power' of the shock wave. Experiments made to verify this explanation brought to light an interesting phenomenon.

It seemed reasonable to expect (though it would not provide conclusive proof of the explanation) that if the vortex could be made to consist of an explosive mixture, its dissolution would not break the continuity of the inflammable column of methane – air in the expansion chamber. The apparatus was therefore modified so that the compression chamber could be filled with an explosive mixture, in the first place of methane and oxygen. The static bursting pressure of the diaphragm was known to within a few pounds per square inch, and the partial pressures to provide roughly the required mixture could be calculated. The oxygen was introduced first and then, quite slowly, methane was passed in through a perforated tube held axially along the chamber until ultimately the diaphragm burst. The exact composition of the mixture was calculated from the observed bursting pressure of the diaphragm. The expansion chamber, in the meantime, had been filled with the methane - air mixture. Very violent explosions, with flame spreading far outside the open end of the expansion tube (100 cm. long), were obtained with many combinations of mixtures in the two chambers. The point of interest, however, is that equally violent explosions were found to occur when the open expansion chamber contained only air.

This finding that ignition could occur when a compressed gaseous mixture was suddenly released into air was investigated further. The mixtures of methane and oxygen in the compression chamber were all on the lean side as a precaution against the destructive violence that seemed likely to develop with intrinsically more explosive mixtures under high compression. Experiments were made with a compression chamber 15 cm. long, and an air-filled open expansion chamber 100 cm. long. Selected results are shown in Table 1; there was in fact some scatter

Table 1

Mixture in compression chamber Per cent methane in oxygen	Pressure at release (lb. per sq. in.)	Result in open expansion chamber
11·8	1,390	No explosion
13·4	775 600	Explosion No explosion
14·8	540 385	Explosion No explosion
15·5	283 245	Explosion No explosion
17·5	193 160	Explosion No explosion

and non-ignitions were sometimes obtained at pressures which were expected to give ignition.

It was found that the pressure on the release of which ignition occurred became progressively higher as the expansion chamber was shortened. Nevertheless, ignition was obtained with mixtures released directly into free air (for example, with a mixture containing 22·3 per cent of methane in oxygen, and a diaphragm bursting at 1,000 lb. per sq. in.).

A photographic investigation of the ignition of a mixture released from compression has not yet been made; however, ignition probably arose as a result of heat transfer from the air compressed and heated in the shock wave to the contiguous layers of explosive mixture (at first cooled by expansion) that formed the driver piston. There was no perceptible delay before ignition.

It seems possible that Hertzberg and Smith's results were confused by the occurrence, in some experiments, of spontaneous ignition when the diaphragm was ruptured before explosion had spread throughout the mixture in their compression chamber. Shock-tubes designed to operate on this phenomenon, with suitably chosen mixtures, might indeed extend their scope. Energy losses during explosion would be minimized, and the design of the tube itself might be simpler since the stressing of the tube would be less severe.

I wish to thank Mr. A. H. A. Wynn, director of the Safety in Mines Research Establishment, Ministry of Fuel and Power, for permission to publish these results.

Use of Adsorption Columns in the Analysis of Emulsions stabilized with Non-ionic Detergents

DETERMINATION of the constituents of emulsions stabilized with non-ionic detergents has been hitherto restricted by the lack of a satisfactory method of quantitative separation. Following the methods outlined previously[1], a separation of such emulsions has been achieved and shown to be quantitative.

Using columns of 'Bio-Deminrolit' (an intimate mixture of 'Zeokarb 225' and 'De-Acidite *FF*') of 40–60 mesh, percolation of lanolin/'Lissapol *N*' emulsions containing up to 1 per cent of sodium chloride gave clear liquors, which on evaporation left no residue. Columns containing powdered animal charcoal as an added adsorbent were equally effective, but although the grease could be removed quantitatively, the 'Lissapol *N*' was held too firmly for successful solvent elution and, eventually, charcoal was omitted from the columns.

Preparation of the columns involves Soxhlet extraction of the resin with the solvents to be used for elution. The columns were prepared in the dry state in tubing 1·5 cm. diameter to give a length of approximately 10 cm. when wet. Satisfactory volumes of eluant were found to be 10 ml. for each 1 cm. length of column.

Elution with 50 per cent aqueous ethanol gave quantitative yields of 'Lissapol *N*', estimated by the method of Oliver and Preston[2]. Subsequent elution with trichlorethylene gave reproducible results for removal of lanolin. These two fractions were also identified with the original materials by their characteristic infra-red absorption spectra.

It would appear that the first step in breaking the emulsion is the removal of stabilizing electrolyte by the mixed resin, followed by adsorption of the grease and detergent. Evidence has been obtained that a chromatographic separation of grease and detergent occurs during elution with aqueous ethanol.

This procedure has been applied to the analysis of 'Lissapol *N*'/mineral oil (Shell Clavus oil 27) and 'Lissapol *N*'/vegetable oil (olive oil) emulsions, giving a 100 per cent recovery of 'Lissapol *N*' in all cases.

The method was further extended to the analysis of a 'Lissapol *N*'/soap/lanolin emulsion by using two separate columns. The 'Lissapol *N*' was separated as above on a column of 'Bio-Deminrolit' and eluted with 50 per cent aqueous ethanol. Soap and lanolin were separated and estimated on a column of 'Zeokarb 225'/charcoal, as described in a previous communication. 'Lissapol *N*' is strongly adsorbed by the charcoal and is not removed when eluting the fatty acid and grease components of the emulsion. A more detailed account of this work will be published elsewhere.

Electrophoretic Movement of Higher Fatty Acids on Filter Paper

ATTEMPTS at the separation of higher fatty acids by paper chromatography have not, in the main, been successful, although Isherwood and Hanes[1] have studied the problem in relation to a number of straight-chain fatty acids, and Nunez and Spiten[2] have evolved a technique, using paper impregnated with olive oil, for chromatographic separation of such compounds. Apart from other considerations, the low aqueous solubility and the low dissociation constants of these acids presented the problem of finding an indicator which would be sensitive enough to enable their presence to be detected on paper. It has been found that the methyl red/bromthymol blue indicator of Duncan and Porteous[3] permits of the detection of small amounts (for example, about 80 µgm. of C_{16}) of acids up to C_{18} on paper. Considerably more care is required, however, in the colour development with the higher acids than with the lower members of the series.

The present work deals with the movement of straight-chain acids from C_{10} to C_{18} in ammonia solution, on paper, in a closed vessel under electrophoresis, and it has been shown that the observed rates of movement, under 6 V./cm., for the C_{10}, C_{12}, C_{14}, C_{16}, C_{18} acids were respectively 4·5, 1·5, 0·33, 0·07 and 0·0017 cm./hr. These observed velocities are presumably the result of the electro-endosmotic flow (approximately 1·6 cm./hr.), a differential adsorption of the acids on paper resulting in a range of R_F values and ionic mobilities of the organic acid anions. When these influences are taken into account, the ionic mobilities would appear to be 42·1, 22·5, 16·4 and 13·9 × 10^{-4} cm./sec./V./cm. for C_{10}–C_{16} respectively. It is not possible to say directly what the figure for C_{18} would be, because this acid is adsorbed so strongly on paper that we have been unable to determine its R_F value under the experimental conditions employed with the other acids, but the extrapolated value is of the order of 13·0 × 10^{-4} cm./sec./V./cm.

The above results for ionic mobilities may be compared with the corresponding figures of Gonick[4] and McBain *et al.*[5] (see Fig. 1).

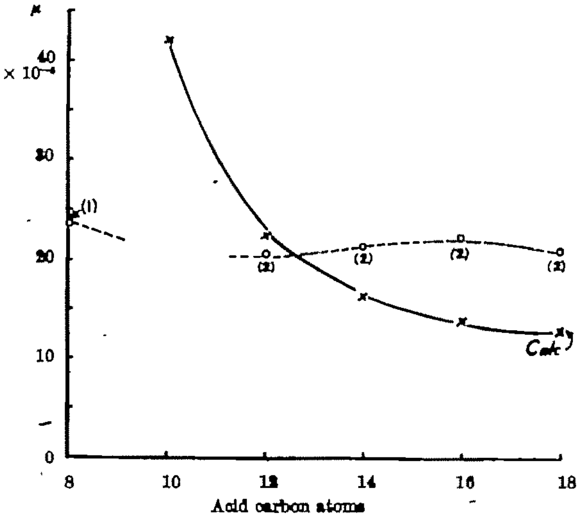

Fig. 1. Ionic mobilities of straight-chain higher fatty acids. ×—×, as determined by the electrophoretic method described; O–O, as determined by other workers: Gonick (2); McBain *et al.* (1)

Oleic, elaidic and stearic acids move at similar rates, and no separation of these from one another is possible; but it has been demonstrated, by the above electrophoretic method, that lauric and myristic acids are present in oleic acid B.P. to the extents respectively of 0·04 per cent and 1·5–2·0 per cent. In addition, another acid, so far unidentified, has been found in oleic acid B.P. which moves more quickly than C_{16} and more slowly than C_{14}. The existence of this acid was confirmed by chromatography[3]. A full account of this work will be published elsewhere.

Production of Electric Power by mixing Fresh and Salt Water in the Hydroelectric Pile

When a volume V of a pure solvent mixes irreversibly with a much larger volume of a solution the osmotic pressure of which is P, the free energy lost is equal to PV. The osmotic pressure of sea-water is about 20 atmospheres[1], so that when a river mixes with the sea, free energy equal to that obtainable from a waterfall 680 ft. high is lost. There thus exists an untapped source of power which has (so far as I know) been unmentioned in the literature.

There are many methods (using osmotic and other forces) which might, in theory, be used for obtaining power by reversibly mixing fresh water and sea-water. In any such process, the extraction of the energy will cool the liquids by a fraction of a degree. The one which appears most practicable depends on the ionic nature of salt and uses membranes (incorporating ion exchange resins) selectively permeable to ions of one sign or the other. If such a membrane separates two salt solutions of different strengths, a potential difference appears across it.

If alternate layers of salt and fresh water are separated by alternate basic and acidic membranes[2], the membrane electromotive forces (each of order 30 mV.) are effectively connected in series, and an e.m.f. large compared with electrode polarization voltages can be built up.

An apparatus (the 'hydroelectric pile') has been constructed; in it 47 acidic and 47 basic membranes, each 8 cm. square, are separated by 93 spaces each 1 mm. thick. Fresh and salt water pass through a system of holes and washers and flow across alternate spaces between the membranes, and current is led off from compartments at the ends of the pile. A continuous supply of electricity is thus obtained. The fresh water becomes slightly salt during its passage through the pile, and the current drawn from the pile accounts for about 90 per cent of the salt transferred.

The maximum e.m.f. obtained has been 3·1 V.; the membranes used (of polythene mixed with resins based on cross-linked polystyrene) have resistivities higher than those of the pure resins, and give the pile an internal resistance of about 250 ohms at 10° C. The maximum external power obtained has been 15 mW. (at 39° C.).

The internal resistance is higher, and the power output is lower, at low temperatures. The pile is therefore likely to be more economic in a warm and equable climate. Its economics probably hinge on the time for which it will run before the membranes need replacing or the interior needs cleaning; the present pile has run satisfactorily for three months on $N/2$ sodium chloride solution and tap water.

This work was carried out at the Chemical Research Laboratory (Department of Scientific and Industrial Research), by permission of the Director of which this communication is published. The gift of membranes by B.X. Plastics, Ltd., and the assistance of the National Research Development Corporation, are acknowledged.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, October 4

SOCIETY OF ENGINEERS (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Miss Marjorie Lovell Burgess: "The Influence of Murdoch on the Modern World".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the LONDON SECTION of the ROYAL INSTITUTE OF CHEMISTRY, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. H. L. Streatfield: "Some Industrial Applications of Metal Cleaning".

Monday, October 4—Wednesday, October 6

SWISS FEDERAL COMMISSION FOR STUDYING HAIL FORMATION AND HAIL PREVENTION (at Zurich)—International Symposium on "Experimental Meteorology".

Tuesday, October 5

INSTITUTION OF GAS ENGINEERS (at the Royal Institution, Albemarle Street, London, W.1), at 6 p.m.—Dr. Alexander Fleck—Murdoch Memorial Lecture

Wednesday, October 6

PHYSICAL SOCIETY, COLOUR GROUP (in the Physical Department, Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 3.30 p.m.—Prof. W. D. Wright: "Colour Measurement Applied to Natural Phenomena, including a Report on Observations made during the Total Solar Eclipse, 30th June 1954".

SOCIETY OF CHEMICAL INDUSTRY (joint meeting of the CORROSION GROUP and MICROBIOLOGY GROUP, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. F. Wormwell and Mr. T. W. Farrer: "The Influence of Micro-organisms on the Corrosion of Metals".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6.45 p.m.—Dr. H. M. N. H. Irving and Mrs. H. S. Rossotti: "The Theoretical Basis of Sensitivity Tests and their Application to some Potential Organic Reagents for Metals"; Dr. H. M. N. H. Irving and Mr. R. G. W. Hollingshead: "An Investigation of 5-Nitroso-oxine as an Analytical Reagent".*

Thursday, October 7

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. Eccles: Presidential Address.

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 4 Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Chairman's Address: "Some Men of Metallurgy".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at the South-East Essex Technical College, Longbridge Road, Dagenham), at 7 p.m.—Dr. Tudor S. G. Jones: "Chromatography—Theory and Some Applications".

Thursday, October 7—Saturday, October 9

SOCIETY FOR WATER TREATMENT AND EXAMINATION (at Bournemouth).—Autumn Meeting.

Friday, October 8

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PHYSICAL CHEMIST to work on macromolecules of biological interest—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3, quoting "Physical Chemist" (October 9).

LECTURER IN ANTHROPOLOGY at the University of Otago, Dunedin—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 15).

LEVERHULME FELLOW AND LECTURER (with good experience of research work in nuclear physics) IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Liverpool (October 16).

PRINCIPAL OF NOTTINGHAM AND DISTRICT TECHNICAL COLLEGE—Clerk to the Joint Education Committee, Exchange Buildings, Nottingham (October 16).

PRINCIPAL (with bacteriological and immunological experience) OF THE WRIGHT-FLEMING INSTITUTE OF MICROBIOLOGY—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (October 18).

CHAIR OF CHEMICAL ENGINEERING—The Registrar, University College, Singleton Park, Swansea (October 25).

SENIOR LECTURER IN ANTHROPOLOGY at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 30).

SENIOR RESEARCH FELLOW (with a first-class degree in physics or electrical engineering and extensive research experience, preferably in high vacuum and electronic techniques); RESEARCH FELLOW (with a first-class honours degree in physics or electrical engineering and good research experience); JUNIOR RESEARCH FELLOW (with a first- or good second-class degree in physics or electronics, with some research experience), IN THE DEPARTMENT OF INSTRUMENT TECHNOLOGY—Prof. J. D. McGee, Physics Department, Imperial College, Imperial Institute Road, London, S.W.7 (October 30).

ASSISTANT LIBRARIAN (preferably graduate in biology, with knowledge of German and French and with library experience) IN THE DEPARTMENT OF FORESTRY—Librarian, Department of Forestry, The University, Oxford (October 31).

LECTURER IN ANTHROPOLOGY, LECTURER IN GEOGRAPHY, and a LECTURER IN PHARMACY, at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 31).

ASSISTANT LECTURER (preferably with experience in some branch of the organic chemistry of natural products) IN ORGANIC CHEMISTRY—The Registrar, University College of North Staffordshire, Keele, Staffs.

ASSISTANT (with a good honours degree in a biological subject and at least two years postgraduate experience in research, university teaching, or scientific administration), to be responsible for the biological sciences (excluding medicine) IN THE SCIENCE DEPARTMENT, London Headquarters—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1, quoting "Biologist".

CHEMIST (with good honours degree, or equivalent qualification, industrial experience and the ability to prepare correspondence and reports) in the London Transport Central Laboratory, Chiswick, to be responsible for a section concerned with a wide variety of analytical and investigational work, dealing with detergents, cleaning materials, fire extinguishing materials, textiles and leathercloths, and many others—Staff Officer, London Transport, 55 Broadway, London, S.W.1, quoting F/HV507.

GEOLOGIST (with first- or second-class honours, division 1, degree in geology) IN THE GEOLOGICAL SURVEY DEPARTMENT, Gold Coast Government, for work in the field, on geological mapping and the application of geophysical methods to water supply and engineering problems—The Adviser on Recruitment, Office of the Gold Coast Commissioner, Melbourne House, Aldwych, London, W.C.2.

METEOROLOGIST (with first- or second-class honours degree in mathematics or physics and preferably with postgraduate experience in meteorology) in the East Africa Meteorological Department, for work including administration, forecasting and other technical meteorological duties—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.57/38/01.

PRINCIPAL or SENIOR SCIENTIFIC OFFICER (with first- or second-class honours degree in physics, engineering or mathematics, or equivalent qualification, and with experience in the field of microwave valves) at the Ministry of Supply Radar Research Establishment, Malvern, for work on the design and construction of millimetre wave magnetrons and other microwave valves, involving fundamental research into processes occurring in such valves and solution of technological problems on construction—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A247/54A.

RESEARCH ENGINEER (with a good honours degree or equivalent, and specialised knowledge and experience in fluid mechanics) for work on hydraulic torque converters and allied subjects—The Director, The Motor Industry Research Association, Lindley, near Nuneaton.

SENIOR EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with H.S.C. or equivalent, and considerable experience of routine mechanical testing, particularly creep testing, and preferably familiar with vacuum techniques) at Culcheth, near Warrington, to supervise work in a creep laboratory using unconventional types of testing on a wide variety of metals and alloys involved in the construction of nuclear reactors—United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 669.

SENIOR PHYSICS MASTER—The Headmaster, Bradford Grammar School, Bradford.

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in chemistry or equivalent, and three years postgraduate experience of inorganic analysis), to take charge of a group engaged on research and development work in inorganic analytical chemistry, including the application of modern analytical methods (Ref. 659); SENIOR EXPERIMENTAL OFFICERS (with H.S.C. (Science) or equivalent and considerable experience in analytical chemistry), to supervise laboratories engaged on analyses of materials used in atomic energy processes (Ref. 660); and ASSISTANT EXPERIMENTAL OFFICERS (with at least H.S.C. in science subjects or equivalent and experience of chemical analysis, preferably in the inorganic field), for analytical work on materials used in atomic energy processes (Ref. 661) with the United Kingdom Atomic Energy Authority, Capenhurst, near Chester—U.K.A.E.A., Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting appropriate Ref. No.

SENIOR LECTURER (with wide experience of flight testing and flight research techniques) IN FLIGHT EXPERIMENTS—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks.

AGRICULTURAL RESEARCH UNDER REVIEW

THAT very useful, if sometimes rather perturbing body, the Select Committee on Estimates, has in its latest report* turned its attention to agricultural research in Britain. It visited some of the research stations and examined some of the directors as well as the chief officials of the Government and other bodies concerned. Besides the verbal evidence, the report includes interesting memoranda by the Ministry of Agriculture, the Agricultural Research Council, and the Treasury ; also a financial appendix showing the funds provided for the various research institutes for the sessions 1953–54 and 1954–55. The inquiry was directed to "the administration of, and expenditure on, agricultural research by the various Departments and organizations involved, but did not extend to the organizations concerned with the practical application of the results". The Committee further decided that policy and the assessment of the scientific and practical value of the work being done lay outside its terms of reference. It is highly gratifying to learn that the Committee "found no evidence of waste or inefficiency in the running of the individual institutes they examined". It did, however, find the overhead organization complex and cumbersome and suggested some simplification.

The complexity arose from historical reasons. Agricultural research in Great Britain is much older than Government interest in it. Rothamsted was founded in 1843 by a private landowner, John Bennet Lawes, and was carried on entirely at his private expense until 1889, when he transferred it to a Trust which he established and endowed and which is within the jurisdiction of the Public Trustee : it received its first Government grant in 1911. Long Ashton was started in 1893 under the ægis of the Bath and West and Southern Counties Society in the grounds of a Somerset landowner, Mr. R. Neville Grenville, for the purpose of introducing scientific methods in the making of cider ; when its supporters wanted to put it on a permanent basis they were advised to form themselves into a limited liability company of a non-profit-making character under licence from the Board of Trade in conformity with the Companies' Act of 1867. The Cheshunt Experiment Station was started in 1914 by a group of glasshouse growers : they, however, were advised to register under the Friendly Societies' Act, though for the new Station at Littlehampton they are to be reconstituted under the Companies' Act. Other stations began as departments of a university ; others, again, were founded by the Development Commission about 1912. From 1911 onwards these institutes received grants from the Development Fund, through the Ministry of Agriculture ; but they had other resources also, usually grants from county councils and subscriptions or donations from societies or individuals interested in their work.

The receipt of a Government grant necessitated submission of the programme of work, estimates of cost, final accounts, and report on work done. Serious difficulties rarely arose so long as the Government grant formed only a moderate part of the whole income: directors and the officials concerned were on very friendly terms and could satisfactorily settle matters in advance of the formal correspondence. The system worked in the usual English fashion in spite of some illogical features. Indeed, it was so successful, and the research institutes expanded so greatly, that by 1931 it was felt necessary to set up the Agricultural Research Council to act as scientific adviser to the Development Commission and the Ministry, to advise the agricultural departments on the programmes of the research institutes, to review, co-ordinate and facilitate all agricultural work in progress and to initiate new investigations where gaps required filling, for which purpose it had funds of its own and could set up its own stations and units. The Council consists of fifteen members: not less than ten are chosen with the approval of the president of the Royal Society for their eminence in science; the others are agricultural. Directors of research institutes are not, in fact, appointed.

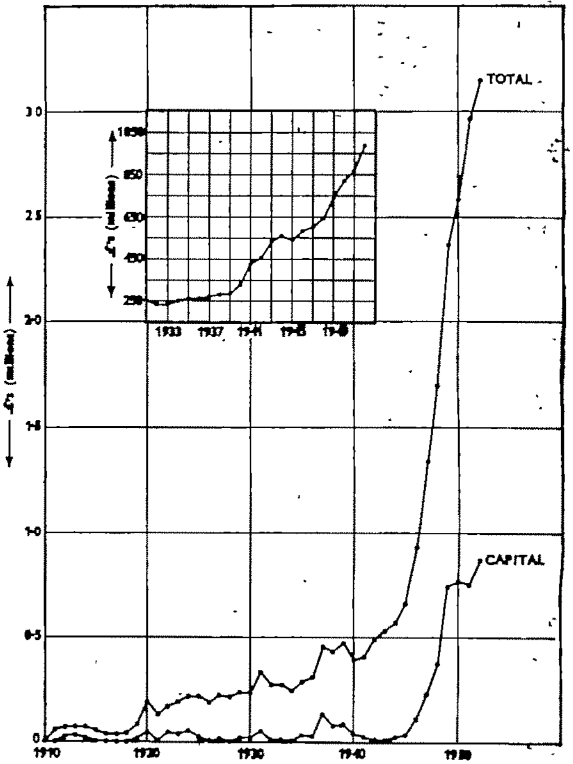
---

* Fifth Report from the Select Committee on Estimates, etc. Session 1953–54. Agricultural Research. Pp. 218. (H.M.S.O.) 6s. 6d. net

The steep increase in cost and the rapid increase in the amount of work has necessitated an enormous increase in the grants (see accompanying graph). Up to 1918 the total annual grants had been about £80,000 a year; by 1944 they somewhat exceeded £500,000; by 1951 they were well above £3 million; and for 1954–55 nearly £6 million. The Government grant, formerly only a fraction of the total income of the research institutes, now amounts to 98 per cent or more of the total, and the Committee considers that this justifies closer examination of the relations of the institutes to the Government. The present relations can only be described as historical accidents. Of the thirty-eight stations reviewed, two are directly controlled by the Ministry of Agriculture, fourteen are independent but come under review by the Ministry jointly with the Agricultural Research Council, and fourteen are directly under the latter body. Of the independent institutes, neither Ministry nor Council is represented on the governing body of Rothamsted, the Ministry has two representatives on that of Long Ashton, and it appoints all the governing body of the Agricultural Engineering Institute. In short, there is just that kind of administrative untidiness that a committee would enjoy straightening out—or recommending that others should do it.

In point of fact, the untidiness is not as serious as it looks. The Ministry's chief work is administration of the various Acts dealing with agriculture; but some of this work—such as plant and animal diseases, seed testing, quarantine—necessitates investigations which are much better carried out on the spot under the eye of the officer concerned than delegated to a research institute miles away. Moreover, the Agricultural Research Council has cognizance of all the research work in all the institutes, either directly or through its committees: there need be no overlapping through ignorance of what is being done elsewhere.

The Select Committee on Estimates, however, was more concerned with finance than with research. The Agricultural Research Council is described as a sister body to the Department of Scientific and Industrial Research, which draws its revenues largely from industrial concerns; and the question arose whether the farming industry could not contribute in like manner to the cost of the agricultural institutes. This was found to be impracticable; indeed, Government grants had dried up rather than stimulated voluntary financial efforts.



State expenditure on agricultural research in Great Britain. Inset: annual gross value of agricultural output in Britain. From "The Agricultural Research Service", by courtesy of the Controller of H.M. Stationery Office

The Committee was much impressed by the fact that no one body is charged with the oversight o the total expenditure on agricultural research. Th Ministry's share of expenditure comes out of th Vote, and the Council's by direct negotiation wit the Treasury; but the Committee found no on whose duty it was to add up these quantities for th purpose of ascertaining the total. The Committe is strongly of opinion that overall savings could b effected if all the institutes could be brought "under one hat", either the Council or the Ministry. Th institutes' representatives preferred the Council: it had more understanding of scientific work, mor flexibility, and was quicker in action. At present th scientific staff is under Council regulations and th non-scientific staff under those of the Ministry; these, however, are quite unsuited to a research institute.

Some of the witnesses were rather perturbed b the fear that they might be brought more directly under the Council than hitherto they have been. S long as the Council remained a purely advisory body the eminence of its members and their persona friendships among the staffs of the institutes gave special value to any criticisms or suggestions the made in regard to the work being done. But, as was pointed out to the Committee, the Council, in its recent booklet, "The Agricultural Research Service", describing its activities, now claims to 'supervise' the State-aided research institutes. The Oxford Dictionary gives as one of the meanings of this word "to superintend", and this in turn means "to have or exercise the charge or direction of". Is this what the Council is aiming at ? The institutes have their own governing bodies chosen for their special knowledge of the subjects dealt with, and it would be a heavy loss if they were abolished or so weakened that no busy man would consider it worth while to serve on them. Sir William Ogg suggested that the happiest relation between the Council and the institutes would be that of the University Grants Committee to the universities, and this idea certainly seems worth following up. Alternatively, the relationship of the Medical Research Council to its institutes might be worth studying. The Committee took it for granted that the large Government grants necessarily entailed loss of independence ; but claims that "the system of direct administration by the Agricultural Research Council promoted greater flexibility both of administration and of the research programmes". The Committee expressed its belief that "this could be done without interfering with the supervision at present exercised by their Governing bodies". It all turns on what exactly is meant by "direct administration". One member of the Committee suggested that there should be on the Council a non-specialist "business brain" to "judge between what is necessary and what is not". Any attempt to do this could lead only to disaster.

Public expenditure on agricultural research is now on so large a scale that full inspection of accounts must be, and indeed is, willingly accepted. The great problem is to find a system that satisfies the canons of sound finance without interfering with the freedom of action essential to the proper conduct of scientific investigation. The Committee learned that Ministers have this under consideration and therefore felt precluded from bringing it within its purview. Our present system no doubt needs tidying up ; but it has, in fact, worked without waste or inefficiency as the Committee recognizes, and, we may add, it has produced a volume of work that in its relation to the available resources will bear favourable comparison with any done elsewhere.

SCIENCE AND LIFE

The Nature of Science and Other Lectures

By Edwin Hubble. Pp. viii+83+2 plates. (San Marino, Calif.: The Huntington Library, 1954.) 2 dollars.

WE owe to the Trustees and Friends of the Huntington Library this last testament of one of the greatest astronomers of our time. The six lectures contained in the book are divided into two groups—three on the nature and meaning of science, and three on scientists and war. Science to Edwin Hubble was the adventure in which man, equipped with his five senses, explores the universe around him. Unlike wisdom, which is peculiar to the individual, knowledge accumulates through the ages and can be passed on from one generation to the next. It piles up against some barrier, until a weak spot is found by an alert research worker, often one who is following a by-path which has stirred his curiosity. Exploration sweeps forward, guided by existing knowledge; old theories are revised, and new theories are formulated as temporary working hypotheses. New laws may be derived to be tested by further observation and experiment.

The success of the scientific method is illustrated by a quotation from George Sarton: "The saints of to-day are not necessarily more saintly than those of a thousand years ago : our artists are not necessarily greater than those of early Greece ; they are likely to be inferior ; and, of course, our men of science are not necessarily more intelligent than those of old ; yet one thing is certain, their knowledge is at once more extensive and more accurate. The acquisition and systematization of positive knowledge is the only human activity that is truly cumulative and progressive".

A by-product of science is technology, the application of the results of science to the service of mankind. Hubble gives an account of the amazing growth of industrial research in the United States during the past thirty years. In this connexion he notes how expanding knowledge, which can be used for evil as well as good, has swept across the danger level, so that men are now in a position to wreck the civilization of the world. The last lecture in the book, "The War that must not happen", gives a grim account of what may take place if we leave our new knowledge at the disposal of traditional politics. Hubble was no pacifist. Before the days of Pearl Harbour, he was urging with all his might the duty of the United States to enter the Second World War and to pay whatever price was necessary to secure liberty for the world. It was with the utmost reluctance that, when war came, he obeyed orders to apply his scientific knowledge to problems of ballistics instead of returning to active service in the United States artillery. But he learnt at the Aberdeen Proving Ground what it meant to face the problems of active warfare unprepared: "The army would come to us with an urgent problem that had arisen in the actual fighting. I would say, 'We don't know, but of course we can find out'. 'Go ahead, find out', the army would say. 'All right. It will take so many men, so much equipment, so much time if we stop other work and give it priority'. 'Time', the army would say, 'hell, we have to cable the answer to-night'."

It is clear that Hubble would have supported wholeheartedly research work to face in advance the problems of the next war, if it should come. But he clearly saw that the modern war of technology is suicide for both sides. War must be stopped if we are to enjoy the potential blessings of new knowledge. Hubble was clear that treaty agreements are not enough. He saw one possible solution—a world authority armed with a police force for the strictly limited purpose of preserving order among the nations. It is the responsibility of all individuals to work to this end—to read up the subject, discuss it and urge the politicians to accept it. The necessity for decision and action is here and now. "We may not like the price, but it is cheap for what we buy—civilisation and life itself." F. J. M. STRATTON

THE CLEAVAGE IN EUROPEAN SCIENCE

Die Krisis der Europäischen Wissenschaften und die Transzendentale Phänomenologie

Eine Einleitung in die Phänomenologische Philosophie. Von Edmund Husserl. Herausgegeben von Walter Biemel. (Husserliana, Band 6.) Pp. xxii + 560. (The Hague: Martinus Nijhoff, 1954.) Paper, 23.50 guilders; cloth, 27.50 guilders.

In this sixth volume of "Husserliana", one is faced with a fact which must be reckoned with before there is any possibility of appraising its contents, or for that matter, even of stating its purpose. This is that, in these pages, Husserl has delivered himself of an act of faith; they represent for him a creed, a system and a philosophy, united in one complex order of thought, and bound together by strong ties of urgency. He appears (as often before) in the role of an Old Testament prophet, telling the savants of Europe what has gone sadly adrift, and how yet all may come right in the end. To read this book (the German syntax of which is sometimes as exasperating as the massive prose of our own John Ruskin, and in some ways not unlike it) is to listen to a cathedral organ, sounding its deepest notes, reverberating and undergoing all manner of reflexions as their waves ascend from nave to triforium.

Thus, the judgment of science upon science itself is seen to consist in the perception of a rift between positivistic objectivism, and transcendental subjectivism. We note that, on this view, it is the cleavage itself more than the tenets involved which is at the root of the development of all subsequent European thought.

As Dr. Walter Biemel so well says in his introduction, the operative phase of the work is the subtle contrast between sections A and B of Part III, wherein phenomenology itself is the only escape from the dilemma: "via the living world or via psychology". The latter, nevertheless, needs adjustment to the appropriate *Methodik* if it is to be effective. The sense of awareness is introduced by the call to philosophy to make mankind awake to the spiritual nature of its end. There is obviously a strong teleological slant in all this, at one with Husserl's veneration for much of the Aristotelean tradition. In fact, he stresses what is well known when he asserts that the basic contribution of Greek thought to the world was its enthronement of theory, not only, so to say, placing it upon a pedestal, but firmly cementing it there. So the split begins to appear as a kind of no-man's-land wherein are likely to be found the logical presuppositions of science (*Sinnesfundament*), which have all too long remained unexamined, and which, thus occluded, have tended to deprive modern science of much of its meaningful content. In a word, why scientists do this or that is, fundamentally, more important than how they do it.

Odd as it may seem, there is a very healthy 'muscular' element at work in all this erudition, as witnessed by Husserl's spontaneous denunciation of a certain type of ***intellektualistischen Snobismus***, connected clearly in his mind with the excesses of higher education. Making every allowance for the prolixity of Teutonic expression, this is always a valuable lesson, and leads on naturally to the essence of the 'cure' to which Europe should submit. In the present book, this appears in the text of a lecture given in May 1935. While science and philosophy remain 'separated', there is little chance of healing the wounds of a discordant civilization, capable—in theory—of a real degree of unity, but kept apart by an artificial competition for the perfection of techniques. When one observes that the gist of all this was expounded at Vienna nearly twenty years ago, it is only too manifest how perfectly it describes our present distresses. Not in vain maybe did Husserl once again assume the part of a seer.

Yet, to British ears something very like this was said (and majestically said) a full century ago in Dublin, and with no less an impact upon the progress of thought. Thus, John Henry, Cardinal Newman, in "The Idea of a University", argued that knowledge was a good in itself, an end for which to strive regardless of gain or loss. But he went further: he said that if, by the exclusion from the curriculum of some essential branch of learning, a gap is left unfilled, then other—and perhaps less worthy—knowledges will be 'tempted' to spill over into it, and thus ultimately to obliterate the original concept. How close this is to the rift between the two domains taken by Husserl as the primary cause of Europe's malaise. Then comes his prescription (in effect) for psychology to make haste to fill it, with philosophy keeping a watchful eye on the process; and, above all, men should not weary. Thus do transcendent minds produce (within limits) a common way for mankind to tread.

"Of possessions," says the Stagirite, "those rather are useful which bear fruit; those liberal which tend to enjoyment. By fruitful, I mean, which yield revenue; by enjoyable, where nothing accrues of consequence beyond the using."

F. I. G. Rawlins

PRINCIPLES OF THE MEASUREMENT OF COLOUR

The Science of Color

By the Committee on Colorimetry, Optical Society of America. Pp. xiii + 386 + 25 plates. (New York: Thomas Y. Crowell Company; London: Constable and Co., Ltd., 1953.) 63*s*. net.

This important work by the Committee on Colorimetry of the Optical Society of America gives an authoritative statement of the principles upon which the measurement of colour is based. The text has been compiled by a number of distinguished American writers over a period of twenty-two years and has now been thoroughly revised and brought up to date by the Committee as a whole. The precision of statement could scarcely be better, and many experienced in the measurement of colour will find a clarity of ideas often lacking in lesser works.

There is also a breadth of view which is refreshing. The first chapter provides a history of colour which begins in prehistoric times, and in further chapters the reader is led by easy stages through the anatomy, physiology, psychology and physics of colour to the technical details of colorimetry itself. No one can pretend that this vast field has been completely described in 340 pages, but the principles of the subject are well set out.

The book is one of principles issued by authority, and as such might be called "The Dogma of Colour" except that the modern meaning of this word tends to include the ideas of arrogant presentation and a disregard for experimental facts, which are by no means in evidence here. The narrative is humbly written, and the authors have clearly been striving to eliminate partisan statements and to give well-informed references to the older workers where these are relevant. The ideas given here so clearly will enable many a worker in the field of colour to tidy up his own mind and liberate himself from loose thinking.

Chapter 1, on the history of colour, is followed in Chapter 2 by a survey of the whole field in general terms. This is illustrated by a number of colour plates built from Munsell papers. Chapter 3, on the anatomy and physiology of the eye, deals mainly with its anatomy, since much of what in the past has been called physiology is given in Chapters 4 and 5 under the heading "Psychological Concepts". Here one finds Müller's and Weber's law, dark adaptation and flicker data and an account of colour-defective vision together with many other subjects. The final Chapters 6, 7, 8 and 9 deal with the technique of colorimetry itself. Chapter 6 on the measurement of radiant energy is followed in Chapter 7 by an account of the standard luminosity data and related subjects, an explanation of the three-colour method of colorimetry and the use of the chromaticity diagram. Chapter 8 details the calculations normally undertaken in colorimetry, and the text is lavishly supplemented with tables. Few books on colour will contain so much useful numerical information. In Chapter 9 colour-measuring instruments and standards are discussed.

In such a work one looks for the very best, and it is a pity that the presentation is not uniformly good. Chapters 7, 8 and 9 are well set out and readable; but the rest of the book, aside from Chapter 1, is dull, and only someone with missionary fervour could read it through completely. Exactness of statement has often been achieved at the expense of easy and interesting reading. The presentation of Chapters 4 and 5 is particularly bad. There are only eleven line-drawings and one colour plate for 72 pages of double-column text, and this alone would bring many a reader to a halt. As a whole, the printing is good, but the colour plates are not up to the standard necessary for a book on the measurement of colour.

The biologist interested in visual mechanisms will find this book a disappointment, and the student is unlikely ever to read it completely; but for the thoughtful colorimetrist it is a statement of basic principles for which he has long been waiting.

L. C. Thomson

BRIDGES

The World's Great Bridges

By H. Shirley Smith. Pp. xi+180+43 plates. (London: Phoenix House, Ltd., 1953.) 15s. net.

When a real authority on a subject can spare the time to write a book about it for the general reader, there is a chance that he will produce a masterpiece. Perhaps this book may be counted as such, for it is at once readable, informative and authoritative. The author was himself responsible for the construction, in Calcutta, of the bridge with the world's longest cantilevered span. He accordingly writes with an intimate knowledge of the problems involved in the building of a great bridge, although the word "great" in the title of the book is not so narrowly interpreted as to refer only to size; in the words of the author, it is used "in its widest sense to include bridges distinguished in their conception and design, those which advanced the science of bridge building, those in which the most formidable difficulties were overcome during construction, and last but not least the mighty spans of today".

Many popular compilations about bridges have been published; but the present book is not another rearrangement of old material. The author has, where possible, studied the original documents relating to each bridge described in detail. The first five chapters, which are concerned with the historical origins, have clearly entailed considerable research, in which the author has been assisted by Mr. Rowland J. Mainstone, who has provided twenty-four pen-and-ink illustrations, which are always clear and often distinguished. An instance of the refusal to accept current notions without verification on the site is afforded by the conjecture that the four arches still standing of the famous Pont d'Avignon are not part of the original twelfth-century structure, as was generally believed. Investigation of the original piers has revealed the presence of springings on a slightly different alignment from the present spans, which may have been reconstructed in the fourteenth century.

Continuing the chronological treatment, the author describes more recent bridge construction, by dealing successively with iron bridges, cantilevers, steel arches, reinforced concrete construction and finally with suspension bridges. The book has an adequate index and a bibliography of source material. A special chapter is devoted to "British Bridges Overseas", on which topic the author is particularly well qualified to write. The large collection of half-tone plates with which the book is embellished have been skilfully chosen to illustrate the author's discussion and are excellently reproduced.

The author himself quotes the statement that "Spain is the land of bridges. In all Europe they have few rivals, . . ." and it is disappointing, therefore, that more space has not been devoted to describing and illustrating Spanish bridges, especially as such quaint legends are attached to some of them: it is said of the bridge of St. Martin in Toledo, for example, that when the architect was finishing it he became aware of a grave error he had made, and, as he was certain that when the centre scaffolding was removed the bridge would collapse, he fell ill from anxiety. His wife, in order to conceal his mistake, set fire to the wood during the night and the bridge did indeed collapse. The architect next time made better plans and no one discovered his first error, as it was believed that the fire had been accidental. The sculptured head above the keystone of the main arch is said to be that of the architect's wife.

If a second edition of this book is required, it is hoped that the author will add a further chapter to give the reader an idea of modern trends in construction and some of the most interesting bridges which are projected. There is at present no mention of the use of new materials such as aluminium, the use of new methods of fabrication such as welding, or the potentialities of two-pin prestressed construction in steel or reinforced concrete; it would be interesting to have the author's views on all these topics and also to hear something of the work already done on such projected bridges as those across the River Severn and across the Straits of Messina.

R. H. Macmillan

50–100 Binomial Tables

By Harry G. Romig. (Wiley Publications in Statistics.) Pp. xxvii+172. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 32*s*. net.

THIS book is concerned with the tabulation of the individual terms in the binomial expansion of $(q + p)^n$ where $q = 1 - p$, and with the cumulative sums of these terms. For each value of $x(< n)$, there are a corresponding term $\binom{n}{x} q^{n-x}p^x$ and a corresponding cumulative sum formed by the addition of all the terms up to and including this particular one. Clearly, all the sequences of cumulative sums are strictly increasing to the limit unity.

The tables provide for values of n lying between 50 and 100 (inclusive) in steps of 5, with p ranging from 0·01 to 0·50 at 0·01 intervals. For values of p between 0·51 and 0·99 we merely replace x by $n - x$ and interchange p and q. All the entries are to six decimal places, and the values of x thus cease in any particular expansion when the corresponding term in that expansion is zero to this order of approximation. For example, when $n = 75$ and $p = 0{\cdot}50$, the largest significant value of x is 59, and the smallest 16.

With the aid of these tables it is thus a matter of seconds to determine the probability of the occurrence of a given number of events (or of that number or less) in a sample of appropriate size. The usefulness of such a book in the field of quality control of manufactured products is thus assured, but (to quote the foreword) there will evidently be many uses for it outside this field.

The author, who was for many years engaged on quality control as a member of the technical staff of Bell Telephone Laboratories, has included a comprehensive introduction to the tables, describing their use and the methods of computation and interpolation used in their construction.

Les Fonctions Orthogonales dans les Problèmes aux Limites de la Physique Mathématique

(Monographies du Centre National de la Recherche Scientifique.) Par Théodore Vogel. Pp. 192+4. (Paris: Éditions du Centre National de la Recherche Scientifique, 1953.) 1200 francs.

MOST engineers and physicists are familiar with the simple but powerful method of solution of the differential equations which occur in problems of wave propagation, heat transmission, etc., and which is applicable in cases where the variables are separable and where consequently the solutions are expressible in series of orthogonal functions. However, a detailed mathematical discussion of these functions is rarely included in text-books of mathematical physics, and T. Vogel's monograph should therefore prove most useful. The mathematical treatment is direct and rigorous, but only as rigorous as is required for use in problems in applied physics.

The contents consist of three chapters. The first is devoted to a study of the general properties of orthogonal functions and differential systems including perturbed systems; the second to some particular closed series, for example, the Fourier series, and other series of orthogonal polynomials and Bessel, Legendre and Mathieu functions; and the third considers several applications to particular problems, including those involving the wave equation with boundary conditions, Laplace's equation in potential theory and in the theory of elasticity, the heat equation $c\rho \frac{d\theta}{dt} = Q + \text{div}\,(\text{grad}\,\theta)$ in heat and hydrodynamics, and examples of calculations in which perturbation and variational methods are most suitable.

S. WEINTROUB

The Moon Puzzle

A Revived Classical Theory correlating the Origin of the Moon with many problems in Natural Science. By N. O. Bergquist. Pp. xiii+378. (Copenhagen: Grafisk Forlag, 1954.) n.p.

THE author of this book, who is a chemical engineer, believes that his theory forms a synthesis between the many puzzles confronting the geologist, palæontologist, geophysicist and astronomer. The main thesis of the book is that about 60 million years ago a planetoid struck the earth and lost so much energy by the collision that it fell into the sun; as a result of the impact a portion of the earth was torn off and afterwards formed the moon. The crust of the earth was given a sliding motion over the core which was tilted some degrees so that the rotational axis of the globe received a new inclination; before the collision there were no seasonal changes on the earth, "because the axis of the earth was not tilted against the ecliptic as it is now" (p. 292). So many changes are said to have occurred on the earth as a result of the collision that it is impossible to refer to all of them, but one in particular may be mentioned. Although the first flood-wave—the immediate consequence of the original impact and the quick acceleration of the earth's rotation—must have caused the death of vast numbers of saurians, the latter were not then completely exterminated. The expulsion of the material that formed the moon, followed by the creation of the Pacific and Indian Oceans and the successive flattening out of the earth, resulting from its increased rotational speed, was followed by the appearance of much dry land. This was unsuitable as breeding places for the saurians and, with other factors, was responsible for a swift end to their existence. Most of the book runs on similar lines, and in its compass of about 100,000 words little is left unexplained. It is doubtful if Mr. Bergquist's appeal to mathematicians to examine his theories will meet with any response.

M. D.

Introduction à la Lecture des Cartes Géologiques

Par Antoine Bonté. Second edition. Pp. 278. (Paris Masson et Cie., 1953.) 1660 francs.

THE subject-matter of M. A. Bonté's book can be roughly divided into those chapters which are primarily concerned with the interpretation of geological maps and structures, and those dealing with ancillary topics—mapping methods, block diagrams, aerial photography, and descriptions of French topographic and geological maps. The book opens with a brief outline of the principles of stratigraphy and correlation, and then goes on to describe tectonic structures in general. The numerous examples are unfortunately illustrated in plan or in section only; more block diagrams would help to remind the reader that geological structures are three-dimensional. Map interpretation proper begins with simple examples of superficial deposits, horizontal beds, V-ing into valleys, etc., and continues with examples taken from the 1 : 80,000 "Carte Géologique de France". Elementary graphical constructions—three-point problems, stratum contours, completion of outcrop, etc.—are explained with carefully drawn diagrams. Igneous intrusions are badly neglected; no mention is made of dykes, sills, ring-structures, or other minor bodies, and even batholiths are dismissed in one page containing a very simple diagram.

This book would be helpful to students who have already had some preliminary instruction in map interpretation, and seek to broaden their outlook. The general standard of the problems lies between that required for intermediate and that of a general degree. It is a useful reference book, because it contains illustrated descriptions of many French tectonic terms, index maps of the "Carte Géologique de France", and a summary of official geological maps of the countries surrounding France, together with names of agents from whom they may be obtained.

GILBERT WILSON

Manual of the Polarizing Microscope

By Dr. A. F. Hallimond. Second edition. Pp. 204. York : Cooke, Troughton and Simms, Ltd., 1953.) 15*s*.

THIS very useful practical handbook is written with particular reference to the series of polarizing microscopes and accessories made by its publishers; but it will be eminently useful to all who have occasion to work with any kind of polarizing microscope. The present, second edition, is greatly enlarged and virtually a new work. The approach is essentially a practical one, with little of the mathematical theory of the microscope, but with emphasis on the necessary adjustments of the apparatus, on he errors consequent on maladjustment, and on the various methods available for the measurement of hose optical constants for which the polarizing microscope is particularly adapted.

After a short historical introduction and chapters on the construction of the polarizing microscope and its accessories, Dr. A. F. Hallimond discusses in detail the methods available for the measurement of optical path-differences, extinction angles, and pleohroism in transparent media. Apparatus for the examination of opaque materials by reflected polarized light is then described, and the theory of the eflexion of polarized light at normal incidence from anisotropic absorbing media is clearly outlined. This leads to the methods of measurement of the constants of absorbing media, including the reflecting power, xtinction angles, rotation of the plane of polarization n reflexion, and path-difference on reflexion, and to the accurate measurement of the constants of an lliptically polarized beam of light. The universal stage is then discussed, including both orthoscopic and conoscopic techniques, and its use in determinations of refractive index. A final chapter deals with the grinding and polishing of opaque minerals, with mphasis on those aspects which differ from metallurgical practice.

M. H. HEY

College Chemistry

A Systematic Approach. By Harry H. Sisler, Calvin A. Van der Werf and Arthur W. Davidson. Pp. x + 23. (New York: The Macmillan Company, 1953.) .25 dollars.

AFTER a decade of teaching, the three authors combined their ideas and wrote "General Chemistry: a Systematic Approach", a text for rst-year (American) university students. In this work they expounded, as well as customary introuctory matter, the electronic theory of valency, the structures of solids, and other theoretical principles elpful in explaining chemical behaviour. Then, instead of leaving these ideas isolated in their several chapters, they applied them faithfully and consistently to explain the chemistry of the elements and compounds they describe. The resulting book contains the finest simple account of the selected modern theory and of its use in interpreting chemical action that the reviewer has so far met.

In response to an appeal the text of 870 pages has been abridged to make the "College Chemistry", now under review. The plan of the smaller book and the logical presentation of subject-matter are as before. The authors explain new terms such as ionization potential, ionic size, ionic radius, atomic crystals and ionic crystals, and point out the bearing of these on chemical action; they describe the Brönsted and the Lewis conceptions of an acid, discourse on the relation of acidity and basicity to electronic structure, and generally throughout the book stress the dependence of property on structure. Electronic configurations of atoms and molecules are extensively used. The subject-matter covers approximately the requirements in general and inorganic chemistry of British intermediate examinations. In addition, there is a section (47 pp.) on organic chemistry and its importance in the world of to-day. There are numerous illustrations and ample sets of questions and numerical problems. This is the kind of inorganic text for which many teachers and students have been looking.

G. FOWLES

Chemistry of Carbon Compounds

A Modern Comprehensive Treatise. Edited by Dr. E. H. Rodd. Vol. 2, Part B: Alicyclic Compounds. Pp. xiv+489–1092. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1953.) 105*s*. net.

IT is in no way derogatory to the sections of this work already published to state that the appearance of this volume has been awaited with particular interest, including, as it does, two highly topical but somewhat complex subjects, the steroids and the triterpenes. For a worthwhile review of these two classes, the middle path of mere competence is of no use whatsoever; the task must be done superbly well or not at all. Fortunately, the editor has ensured the necessary excellence by calling on Prof. D. H. R. Barton to expound the intricacies of the triterpenes, while the steroids are in the able hands of Prof. and Mrs. C. W. Shoppee (steroid studies seem conducive towards husband and wife partnerships). From these authoritative sources one expects a great deal, and expectation is fully justified. The complicated elucidations of structure are clearly described, and stereochemical implications are kept well to the fore. Especially welcome is the admirable and timely survey of the recent remarkable synthetic feats in the steroid field.

Prof. Barton (aided by Dr. S. H. Harper) has also shouldered the burden of describing the simpler mono-, sesqui- and di-terpenes. Much of this work is solidly classical; but recent studies are also fully discussed, one of the most interesting being the elucidation, at long last, of the structure of caryophyllene and its congeners.

In a book of this scope, clear presentation of the complex formulæ involved is essential, and here one can only regard the feats of the compositor with awestruck gratitude. The flow-sheets, especially, are models of clarity and, although errors inevitably occur (for example, omission of the 11-keto group in some formulæ on p. 976), they are few and relatively trivial.

R. A. RAPHAEL

RESEARCH ON THE MAMMALS OF AFRICA

By Dr. L. HARRISON MATTHEWS, F.R.S.
Director, Zoological Society of London

LITTLE more than a hundred years have passed since hunters such as Gordon Cumming were at their work among the vast herds of big game in the southern quarter of Africa, and little more than fifty since Selous was making a living by ivory hunting somewhat farther to the north. All those countless thousands of animals have now disappeared for ever; a few survivors are scattered over parts of the country, and some herds remain where they are preserved in the National Parks. The opening-up and white settlement of East Africa did not come until later, but although the same process of decimation began, and many parts of the country have been cleared of game, it is still possible to see great herds of wild animals that recall the accounts of conditions in South Africa given by the early travellers.

Nevertheless, the presence of enormous herds of game animals is quite incompatible with the economic exploitation of the country and the rapid expansion of the native population; the game must go, and there can be no hope of its survival outside the National Parks and game reserves. It is probable that within a century all the game of Africa will be enclosed within fences (or excluded without), and some species will have been exterminated. As yet, however, there is practically no information available on the biology of these mammals, information that is essential for successfully managing such parks and reserves. Little if anything is known of the carrying capacity per acre, in terms of game animals, of any African territory, nothing exact about the numbers of animals normally present or their fluctuations, about breeding-cycles, food preferences and requirements, or the effects of game on the environment, about the relationships of prey to predators, the incidence of parasites, and innumerable allied subjects.

Although such vast numbers of animals have been available to observation, it is surprising that so little is known about the biology of any species. A great quantity of scattered notes has been recorded about the distribution of game animals, and a small amount about their habits; but few indeed are the naturalists who have set out patiently to investigate all the details of the life-history of any one species. The information available comes mostly from sportsmen whose main interest is in killing animals, or from the casual observations of the tourist who has neither the ability nor the inclination to make a really serious study of them. Much incidental information has been collected by the numerous scientific expeditions that have gone into the field; but the main object of even their activities has been to collect dead specimens for museums rather than to study living animals. A notable exception, though it worked in Malaysia and not Africa, was the Asiatic Primate Expedition of 1937[1,2], financed by the Carnegie Institution and other American bodies, which devoted much time to studying the biology of pes as well as to collecting material for laboratory xamination and for museum exhibition at home.

Many museums throughout the world have been at pains to send out expeditions for collecting specimens "before it is too late"—yet how many complete skeletons of such a common animal as the tiger, for example, are available for study among the institutions up and down Great Britain? Now at last some zoologists are trying, also before it is too late, to make some study of the biology of the numerous interesting mammals that may not be available for study under completely wild conditions in the not so distant future. During the past twenty years a start at least has been made, and several workers have made reports upon the biology o single species that form a modest beginning to the volume of work that may be hoped for in the years to come.

Although the African elephant-shrew is a smal species and cannot be classified with the game animals, the researches of the late Prof. C. J. Van der Horst[3-5] on this creature must be mentioned here for they were among the first that offered an intensive study of any species of African mammal. They were concerned chiefly with problems of the breeding cycle, with the extraordinary phenomenon of superovulation that is very pronounced in this species and with placentation and development. Van der Horst's untimely death was a great blow to the study of African mammals; it is much to be hoped tha worthy successors will be forthcoming to fill the gap left by his loss.

In the years before the Second World War I was able, thanks to a grant-in-aid of expenses from th Royal Society, to spend some time in East Africa studying the reproduction, bionomics and systematic of the spotted hyæna[6-8]. The results were incorporated in several papers, and were privileged to be among the first to present an attempt at a comprehensiv account of all the main aspects of the biology of any of the larger African mammals. The investigation o the reproductive anatomy and habits of the hyæna which had been the subject of peculiar legends sinc the time of Aristotle, and probably long before showed that the hyæna's well-known propensity fo prolonged bouts of ribald laughter is, by anthropomorphic standards, not without foundation. During the course of this research it was possible to collec much information on the biology of some of th smaller mammals of Tanganyika.

Immediately after the War, Prof. P. A. Buxton was struck by the great waste of biological materia inseparable from the methods of elephant control i tropical East Africa, and was the moving spirit i forming the Elephant Research Committee that wa responsible for sending Dr. J. Perry to Uganda fo two years, primarily to study the reproductive cycl of the African elephant in the wild. Perry's papers[9,10] on this subject, and on several other aspects of th biology of the elephant, are an important contributio to African zoology, and his incidental researche on other African mammals have provided a larg amount of valuable material.

Concurrently, Dr. Lorna Kellas was working in Tanganyika on similar problems in the dik-dik, one of the lesser species of antelope that, by reason of their small size and the luxuriant cover available, are among the less conspicuous of the game animals. The results of her researches[11], now in the press, give a complete account of the breeding cycle and the placentation, and much other information on the biology of these beautiful little creatures. Dr. Kellas has recently been in Africa again, collecting biological material during a great 'kill-out' of game in a campaign against the tsetse fly in the southern Sudan, and it is confidently expected that her studies will add considerably to our knowledge of the biology of African mammals. An endeavour is being made to continue this collecting when operations are resumed next season.

Investigations into the incidence of yellow fever in East Africa and into methods for its control have necessitated considerable studies on the biology of the mammals other than man that act as reservoirs for the parasite causing the disease. The researches of A. J. Haddow[12] on the biology of the red-tailed monkey of East Africa, made in connexion with the yellow fever research, form one of the most complete investigations of any single species of African mammal, and bring together with a mass of original observations all that is known of the species, from its habits, ecology and parasites to the native legends clinging to it. Further contributions on other species are awaited from this author.

The latest similar investigation, which is still in progress, is that of Allan Brooks, who while holding a Colonial Research Fellowship has made a three years study of all aspects of the biology of the Thompson's gazelle of Tanganyika Territory. During his work he has been attached to the Tanganyika Game Department, from which he has received unlimited support and to which he has been able to render no little assistance.

It is greatly regretted that when the clearance of the country for the abortive ground-nuts scheme was undertaken no zoologist was informed of the material that might have become available for scientific examination. As a consequence, more than nine hundred black rhinoceroses were slaughtered and left to the hyenas and vultures—a timely postcard to the right quarter could have ensured that a zoologist would have been enabled to take advantage of this great destruction and have turned it to some use in elucidating many of the unanswered questions about the life-cycle of this interesting species. It is hoped that arrangements can be made to take advantage of a 'kill-out' of black rhinoceros on a much smaller scale (about fifty animals) that is shortly to be undertaken in an area of Uganda.

The desirability of making a proper scientific investigation of the mammals of Africa while there is yet time has now received official recognition, for the Game Subcommittee of the Tsetse Fly and Trypanosomiasis Committee of the Colonial Office has recommended the establishment of a team of biologists for the purpose. It was proposed that this team should work in one of the East African territories, and that it should be financed by the Governments of Tanganyika, Kenya and Uganda jointly; the arrangements were nearing completion two years ago when the promised financial support was withdrawn by one of the Governments at the last moment, and since then political disturbances have precluded a renewal of negotiations. The matter will no doubt be taken up again as soon as conditions are more favourable.

In the meantime, it is interesting to note that a fully qualified zoologist has now been added to the establishment of the Game Department of Tanganyika Territory, and one, unfortunately only temporarily, to the Veterinary Department of the Sudan; both these officers are now at work in the field. It is much to be hoped that other Governments will follow these examples and make similar appointments. The Scientific Council for Africa South of the Sahara, and the Colonial Office, are both supporting the efforts being made in various quarters to promote research on African mammals, and the Colonial Office is at present employing a zoologist to prepare a historical survey of the past and present distribution of the more important mammals. This work is being done by Miss O. J. Sidney, who has been provided with accommodation in the library of the Zoological Society of London; her researches are approaching completion and will be an invaluable background for future field workers.

The latest enterprise to promote research on the African fauna is a study-leave course primarily for officers in the Game Departments but also for those officers in other Colonial services who have the inclination and opportunities for field-work. The course is designed to give officers who have had no academic biological training some understanding of the biology of mammals and of the scientific approach to its study, and in particular to give some help in the problems that can profitably be taken up in the field by those whose tastes lie in that direction. The course consists of a fortnight's instruction at the Zoological Society of London, including demonstrations, practical work and reading; a week in the Department of Mammals at the British Museum (Natural History), where systematics and local faunas are studied; and a fortnight of instruction and demonstrations on problems of the breeding-cycle at the Royal Veterinary College. The first experimental course was held in the autumn of 1953, and at the request of the Colonial Office a second course is being provided in 1954. It is hoped that this course will become an annual event and that its usefulness will grow as experience is gained in meeting the special needs of those attending so that they may derive the utmost benefit from it.

Time is short, practically everything still remains to be done; but there is a considerable body of enthusiastic people who, if given some basic instruction and guidance, can lay the foundations for the proper investigation of the fauna of tropical lands. The information that they can collect is desirable in itself for academic science, and is essential for arriving at the correct methods of wild-life management in the National Parks and reserves where all the large species of land animals will sooner or later be segregated.

GENETICS AND THE ADVANCEMENT OF SCIENCE

THAT zoologists and botanists, on September 6 devoted a whole day's joint session at the British Association meeting at Oxford to discuss genetics in relation to other biological sciences is perhaps evidence enough for its importance and central position. The subjects covered by the speakers, which included taxonomy and evolution, biometry and animal and plant breeding, medicine, physiology and microbiology, confirm this view. If this were not proof enough, the different methods of exposition adopted by the speakers—the historical, the broad generalization, the concrete examples illustrating one or two points, the read paper and the extempore—were in themselves a living and immediate demonstration of the great influence genetics has on human behaviour—that subtle character which is generally believed to be most tractable. This unconscious genetic experiment had its control group, for three of the speakers, all of them different in their methods, come from the same environment—the school founded by Bateson. If identical twins, trained in different schools, had been included among the speakers the experimental design would have been well-nigh perfect.

In discussing taxonomy, Prof. J. Heslop-Harrison said that almost every aspect of genetical research is relevant to taxonomy, but it would not cause a revolution in the system. Its contribution was to be found in the concept of a species as a biological unit, and that species differed generally in complex genic or structural chromosomal differences which had accumulated gradually over a long period. Genetics had revealed the nature of interspecific barriers, and a study of breeding systems as well as chromosomal analysis was essential for the proper assessment of a group: evidence for this was seen in the difficult taxonomic genera which had since been found to have an unorthodox breeding system such as apomixis. Because the full effect of genetical research had not yet been felt in taxonomy, a plea was made for reciprocal exchange of ideas and results from the two disciplines. Perhaps the speaker was unaware that geneticists are often greatly impressed with classification, because its groupings are usually confirmed by genetical studies. It would be too much to hope that genetics could give to the whole of classification the meaning and unity which atomic physics has given to the far simpler classification of the atomic table, but in some families a comparable correspondence between taxonomic differences and genetic structure can be found.

Prof. K. Mather, in his historical account of the internecine war within genetics between the Galton–Pearson group of biometricians and the Bateson school of Mendelians, traced its origin to the entirely different experimental approach adopted by the two sides to the problem of heredity. Mendel studied single sharply defined characters in carefully chosen material, the pure breeding pea, and he ignored all other variation. The confirmation of Mendel's laws by Bateson in many other plants and animals showed its wide application. Galton and Pearson, on the other hand, attempted to take into account the whole of the variation by measuring individuals, and dividing the variation into heritable and non-heritable from the correlations of these measurements for parent and offspring. The type of continuous variation found by Galton did not agree with the discontinuous variation found by Mendel. The synthesis of these was made by Sir Ronald Fisher in 1918 when he showed that a continuously variable character such as height in man could be explained on Mendelian laws by merely postulating a number of genes each with a small effect. This synthesis has been developed and is now being applied to practical breeding. But Prof. Mather pointed out that present biometrical methods such as the analysis of variance were unable to cope with the great complexities of gene interactions which occur with such polygenic systems.

Darwin was handicapped when formulating his theory of evolution by not having a basis for heredity, for he was unaware of Mendel's work. This importance of genetics for the interpretation of evolution was illustrated by Dr. E. B. Ford, who described his recent researches in the laboratory and field with butterflies. Much of Dr. Ford's earlier work had shown that the expression of a heterozygote could be altered by selection, as originally postulated by Fisher. In other words, the dominance properties of a gene could be changed. A colour pattern which in the wild was controlled by a gene with incomplete dominance—the heterozygote being intermediate between the two dominants—could be easily changed to full dominance by selection in the laboratory. That dominance was not present in the wild indicated that the heterozygotic intermediate phenotype had some selective advantage over the two homozygotes. Polymorphism for wing spotting in wild population in south-east England and the Scilly Isles had been mapped in relation to natural barriers. Small changes in vegetation in areas across an island were enough to separate populations having either a bimodal or a unimodal distribution of spots.

Turning to the practical application of genetics: Dr. A. Robertson pointed out how the early attempts in animal breeding to combine high milk yield and high fat content had failed to give the expected results on Mendelian theory, because the synthesis of biometry and mendelism had not then been made. The large number of genes concerned in these two characters, even without the complication of linkage, would require very large progenies to recover the desired combination. But the biometrical background had since been applied to practical problems with great success, particularly in the United States. A principle had emerged that with a character of high selective value there would be little genetic variation left on which to make further selection, but with a character of low selective value there would be a store of genetic variation. The application of genetic principles depended upon the type o breeding system adopted by the whole society o stock raisers. The selling of bulls from a few herds—bulls which conform to the fashionable but false standard of shape—means that all the herds of a breed are permeated with the genes from the few bull-selling herds. The use of such bulls within the existing breeding system was the cause for the failure of artificial insemination to increase milk yields. To get the full value of artificial insemination the criteria for selecting bulls must be changed.

The plant and animal breeders' problems are fundamentally similar, but differ in detail such as the number of individuals that can be raised. The large and expensive animal is a severe limitation on numbers which would never trouble a wheat breeder

Prof. S. C. Harland described how plant selectors and hybridists without any genetical knowledge had obtained great success. But this was due to the accommodating nature of their material, and the use of genetical principles would have speeded the results. The concept of 'gene erosion' was a problem which all breeders had to face. Rigorous selection for one character was usually accompanied by a loss of 'fitness' genes. For example, the selection of large flowers in sweet peas had produced sterility under certain conditions. Such unbalanced types would not survive in the wild; but the unbalance was to a certain extent counteracted by the artificial environment of agriculture. Thus the main problem is one of genotype and environment, the study of which requires both genetics and physiology. Another important factor was mutability, for the problem of releasing variability in some material is a real handicap to the breeder. To-day, plant improvement rests largely on complex characters such as disease resistance, and hence a full knowledge of the genetics and biochemistry of physiological races is necessary.

The problems of human genetics have to be tackled differently from those in animals and plants. Prof. L. R. Penrose showed how many different morphological and physiological peculiarities are known now to be due to single genes. Some of these effects can be mitigated by treatment, others cannot. There was a fallacy in the argument advanced by some geneticists that under the cover of improved hygiene and nutrition the population is said to be deteriorating genetically. The example of the relationship between sickle-cell anæmia and resistance to malaria was evidence for this fallacy, for it showed that a gene need not necessarily be wholly good or bad. The gene for sickle-cell anæmia in a heterozygote confers complete resistance to malaria, a property which is of obvious advantage in tropical countries. In this case the hygienic control of malaria actually reduces the incidence of the sickle-cell gene. The full physiological effects of genes and the future requirements of the human race are not known, and since variety is generally advantageous it was an unsound policy to try and get rid of genes by sterilization.

The physiological effects of genes was discussed by Dr. D. Lewis, who stated that the gene, although its conception had changed from the billiard ball to a piece of chromosome of varying complexity and length, was still a working physiological unit. The effects of the gene controlling sexual incompatibility in plants was known in sufficient detail to enable us to draw a close parallel between the type of genetic control and the physiological mechanism. This relationship between genetics and physiology had a predictive value which could be applied to quite different systems; for example, to the relationship between a host plant and its fungal parasite. The cytoplasm—that other hereditary factor, less rigorous and usually subservient to the gene but a factor which plays the major part in differentiation, ageing and perhaps short-term adaptation—was now beginning not to obey rules but at least to show remarkably similar properties in organisms as diverse as the tomato, fruit fly, *Paramecium* and yeast. Since the gene was the prime cause of all physiological effect, and the cytoplasm was the means of transmitting that effect, a genetic study from the gene outwards and a physiological study inwards provided a fruitful meeting ground for collaboration.

The application of genetics to micro-organisms, particularly those which have no normal sexual cycle, was described by Dr. J. A. Roper (in a joint contribution with Dr. G. Pontecorvo). On the classical genetic theory the reassortment of genes required sexual reproduction, but in several asexual micro-organisms a 'para sexual' phenomenon occurred which made genetic analysis possible. In bacteria, transformation by a pure nucleic acid occurred; in filamentous fungi, exchange of whole chromosomes or even somatic crossing-over occurred. Micro-organisms were particularly suitable for physiological genetics where the specificity of each gene determining a single biochemical reaction had been found in great numbers.

The importance of micro-organisms was emphasized by Prof. C. D. Darlington in his summing-up. In micro-organisms development was telescoped in such a way that the gene was closer to the character, until in the virus the gene and the character were one. The almost unnoticed demonstration in 1924 of the precise segregation of characters in the four spores of a moss transferred Mendel's laws from a statistical to a direct observational basis. The taking of genetics into the field and city, that is, into real life, had begun, and a similarity of the field-work of Dr. Ford on butterflies and the sickle-cell anæmia by Allison referred to by Prof. Penrose indicated that the whole of human society could be a vast genetic experiment. But Prof. Darlington ended his talk by saying that in view of the failure of the universities and especially the social scientists to keep abreast of the advances in fundamental or genetic biology, Dr. E. D. Adrian's suggestion, in his presidential address, that mankind should be handed over for treatment to the social scientists made him "gasp".

The genes are, to use Darlington's phrase, the "long-range determiners" of not only morphological peculiarities but also of human behaviour: this is still not realized in universities and many research institutes. As for the public, it has always loathed the idea of genetic determination and has clung to the cherished and flattering old wives' tales that come within the framework of Lamarckism and not of genetics.

D. LEWIS

WEATHER FORECASTING

THE discussion on weather forecasting, arranged by Section A (Mathematics and Physics) of the British Association and held in Oxford on September 6—as might be expected after a disastrous summer with weather more than usually a matter of public concern—drew a large gathering to the Sheldonian Theatre. The chair was taken by Prof. E. H. Neville and later by Sir Harold Spencer Jones, who introduced the guest speaker from Sweden, Prof. C. G. Rossby, now director of the Meteorological Institute of the University of Stockholm but equally renowned for his work in the United States, having held chairs in both Chicago and the Massachusetts Institute of Technology.

In opening the discussion with a paper on weather forecasting as a problem in physics, Dr. R. C. Sutcliffe first remarked that weather forecasting is something more than the science on which *it* rests; it is a scientific profession with some hundreds of practitioners issuing some thousands of forecasts daily for a wide variety of purposes. In a short paper it was possible only to indicate the general nature of the scientific problems; but in weather forecasting where it is impossible for every interested member of the public to be given personal advice on his own particular problem, it is particularly important that the client should have some understanding of the subject.

The problems of weather forecasting may be regarded as falling within the scope of hydrodynamics, but the methods which have been successful in other fields have so far contributed relatively little to the practical problems of weather prediction as they arise from day to day. This is because the problems are extremely complex, being concerned with non-steady and turbulent motions in the compressible fluid of a heat engine working against friction. The system is not even closed, and the composition of the fluid is continuously changing by evaporation, condensation and precipitation. Meteorology must therefore be studied as a science in its own right, and predictions about the atmosphere must depend on its observed structure and behaviour.

Dr. Sutcliffe was mainly concerned to emphasize the different scales of atmospheric systems. On any one day the circulation of the atmosphere differs widely from the long-term climatological mean, and examples from surface and upper-air weather maps of the northern hemisphere were used for showing how depressions and anticyclones frequently form over periods of one or two days. These systems are well understood scientifically and, as Prof. Rossby showed later, can be predicted by hydrodynamical theory; but they are essentially a form of large-scale turbulence and after a period of one or two days predictions become very uncertain.

Variability is present on many smaller scales—frontal systems, vertical convective systems down to variations on the scale of kilometres and metres. Much of this variability is beyond the reach of regular observations and can only be treated in statistical terms.

Weather forecasting, Dr. Sutcliffe remarked, can be regarded as based on five considerations: (1) the change in the large-scale synoptic situation; this can give for one or two days ahead the broad character of the weather and wind; (2) the effects of fronts—allowing fairly accurate timing of rain areas and major changes of wind, temperature, etc., for periods of some 12 hr. ahead; (3) the convective properties of the air masses—permitting statistical-probability statements on showers, thunderstorms, convective cloud, visibility, etc.; (4) diurnal changes—these are major considerations for temperature, humidity, convective phenomena and visibility; and (5) topographical effects—these introduce many local differences in weather.

Although formally these aspects may be considered separately, they are not independent.

Owing to the rapidity with which changes take place and to the element of dynamical instability which enters into the developments, there seems no present prospect of eliminating uncertainty from weather forecasts. Dr. Sutcliffe expressed himself as optimistic about dynamical meteorology, which has made great progress in very recent years; but he was not optimistic about persuading the atmosphere to behave in a more orderly way.

Mr. V. R. Coles spoke of the work of a practising forecaster. The forecaster depends in the first place on obtaining adequate observations, and the absence of reporting ships in some areas, for example, south of Greenland and even in the Bay of Biscay, is often a serious handicap. The stationary ocean weather ships in the Atlantic are a great boon. The erratic behaviour of depressions was illustrated by examples where extrapolation would give a good prediction and others where it failed completely. In recent years much attention has been given to upper-air conditions, and relationships between the consideration of the upper thickness or thermal patterns and the development and movement of surface depressions have been established. Mr. Coles illustrated the success of this method with an example of the rapid formation of a new anticyclone which had been very satisfactorily predicted. The methods of extrapolation, the use of tendencies and the indications from the upper air are not always consistent, and Mr. Coles thought that if much greater accuracy in forecasting is to come, it will probably be by the use of objective methods of calculation using electronic methods.

The first two speakers were mainly concerned with forecasts for some 24 hr. ahead made familiar to the public by Press and broadcasting, and it fell to Dr. J. M. Stagg to consider the possibilities of prediction for longer periods. Experience has shown, he said, that attempts to extend the forecasts to a few days ahead by the methods discussed by earlier speakers meet with little success; the accuracy falls away very quickly after the first 30–36 hr. But nevertheless, it is a commonplace observation that weather has a 'moodiness', and generally bright or dull or rainy weather may persist for long periods. Meteorologists have therefore looked for something in the atmosphere more enduring than the simple depressions and anticyclones.

Dr. Stagg referred first to certain purely empirical methods to which much attention has been given. The field of surface pressure has been elaborately analysed for periodicities and correlated with measures of geomagnetic and solar activity, and although much has been learned about the modes of oscillation of our atmosphere, little of prediction value has resulted. A phenomenon referred to as symmetry in the pressure–time curve has been discovered in Germany, in which variations of pressure have been shown to repeat in reverse order after a point in time known as a 'symmetry point'. But tests made in England were no more successful than others based on extrapolations of pressure trends; by the time a trend has become established it is already on the way to another rhythm or pattern. Methods of correlation, although they have had some success in India for monsoon prediction, generally fail in a similar way. It is not surprising that the atmospheric machine produces good relationships for a time in a particular area, as these would reflect the mode of circulation during the period; but if the mode changes, so will the correlations, and their prediction value may well be slight.

Dr. Stagg sees more of scientific interest in the dynamical-synoptic studies using mean weather charts for periods of days. In the United States, the Weather Bureau has introduced forecasts for five days, and more recently for thirty days ahead, on the basis of continuity in the evolution of mean upper-air charts over these periods. The methods have apparently had a measure of success, but are still mainly empirical, depending largely on the extrapolation of trends which may suddenly change for no known reason.

In the U.S.S.R. most attention has been given to the movements of anticyclones as the more enduring features of the synoptic patterns, and Dr. Stagg thinks it is no coincidence that long-range forecasting has been established in the great continental areas. Over the British Isles we are next door to one of the world's worst cockpits of weather disturbances, and even a slight error in predicting the mean tracks of depressions can make a forecast completely wrong for the whole country. Dr. Stagg stressed the need for physical understanding of the processes, and referred to research going on in the Meteorological Office; but he also reminded the audience of a remark made by Sir Gilbert Walker, speaking to the British Association twenty-one years ago: "Though the prestige of a meteorological service may be raised for a year or two by the issue of longer range forecasts, the harm done to the science will inevitably outweigh the good if the prophecies are found unreliable".

Prof. Rossby introduced the subject of 'numerical weather forecasting' by referring again to the broad spectrum of frequencies in atmospheric disturbances which was the theme of Dr. Sutcliffe's paper. 'Weather', in the sense of clouds and rainfall, is produced mainly by the smaller-scale disturbances which have relatively large vertical components of motion. The largest scale motions, with dimensions of some 5,000 km., are necessarily quasi-horizontal, and it is these motions which have now been shown to be amenable to direct calculation with useful accuracy. The calculations will not produce a detailed weather forecast; but they may still prove to be of much assistance to the forecaster by keeping him on the correct broad lines over periods of one or two days.

The conception of forecasting by calculation on the basis of the physical equations originated in Britain with the late L. F. Richardson some thirty years ago, but the ideas were at that time quite premature as there was no practicable way of carrying out the heavy computations. It was not until 1947 that the subject was taken up seriously at the Institute of Advanced Studies in Princeton, and since then there has been rapid progress on a research basis not only in the United States but also in Britain, where the work of Sawyer and Bushby is outstanding. In Sweden, with its present limited facilities for electronic computing, Prof. Rossby has confined attention to the simplest model of large-scale atmospheric behaviour, but he expects to be in a position to introduce more elaborate and realistic calculations in the near future. The basic idea was put very simply by Prof. Rossby. It has been shown that the vorticity (about the vertical axis) of the mean motion of the atmosphere is nearly a conservative property. It can therefore be advected with the mean motion. But by integration, with known boundary conditions, the motion itself can be calculated from the vorticity field so that, using a step-by-step method, it is possible to begin with the present known motion, determine the new field of vorticity for, say, one hour ahead by advection, compute the new field of motion by integration and so continue indefinitely until such time as accumulated errors render the calculations worthless. Mathematical refinements have improved on this simple scheme, but the principle remains the same.

Prof. Rossby remarked that "a weather forecast is a rather perishable commodity which must be marketed quickly". Only electronic methods can reduce the time of calculation to anything reasonable, as even in his present simple model there are 10^7 operations to carry out to produce a 24-hr. prediction. But it now seems that the time spent in calculation will not be the most serious item. Much more time will be spent in making, transmitting and collecting the observations from the large area involved (some six hours) and in plotting and analysing the charts (some three hours). Attention will have to be given to these factors, and already objective analysis and diagrammatic recording are being studied.

To show once more that the computations can deal only with the broad synoptic situation and not with the details of weather, Prof. Rossby provided a diagram showing the distortion which may take place in a layer of fluid over a period of a day or two. Beginning as a chequered square of some 500 km. side, the 'fluid element' altered shape by hydrodynamical 'deformation' as though it were a handkerchief flourished in the magician's hand, with all pattern becoming confused in the folds. To analyse such motion in the practical case would require the number of observations to be increased by one or two orders of magnitude.

It was regrettable that time did not permit of general discussion after the papers, but perhaps the mistake had been in making the subject so broad. Weather forecasting is concerned to some extent with almost the whole science of meteorology, and any one of the four papers could have provided the basis for a profitable morning's symposium.

OBITUARIES

Dr. E. S. Russell, O.B.E.

In the death of E. S. Russell, on August 24, zoology lost one of its foremost thinkers. Many knew Russell as a friendly and quiet companion, who even as president of the Linnean Society of London always seemed to be as it were 'off duty'; but the formidable character underneath was revealed, for example, in the concluding passage of "Form and Function" (Murray, 1916):

"Dogmatic materialism and dogmatic theories of evolution have in the past tended to blind us to the complexity and mysteriousness of vital phenomena. We need to look at living things with new eyes and a truer sympathy. We shall then see them as active, living, passionate beings like ourselves, and we shall seek in our morphology to interpret as far as may be their form in terms of their activity.

"This is what Aristotle tried to do, and a succession of master-minds after him. We shall do well to get all the help from them we can."

Those were remarkably confident words from a man not thirty years of age. By now, thirty-eight years later, we have experienced part of the fulfilment of his demand, in the insight gained into the nature of animals by von Koehler and Bierens de Haan, by Lorenz, von Fritsch and Tinbergen; and the corresponding morphology is clearly on its way, indeed begun, by Baerends and others.

All Russell's books are exciting, alike for their scholarly marshalling of facts and for their heterodoxy. Lamarck and Samuel Butler receive honour only a little less than that accorded to his chosen guides: Aristotle, Cuvier, von Baer and Johannes Mueller.

From 1921 to 1945 Russell was director of fishery investigations in the Ministry of Agriculture and Fisheries. As a fishery naturalist he had shown a talent for handling statistical material, conjuring biological and ecological discoveries from the records of quantities and sizes of fish on the fish-markets. Later, he decided to clarify the problem of the relation between the yield of a fishery and the vital processes that produce it: growth and reproduction, less mortality. Starting from first principles, he published, in 1931, "Some Theoretical Considerations . . .", and, as it transpired, ushered in a period of new understanding of this problem.

In the Conseil Permanent International pour l'Exploration de la Mer, Russell was an active officer; and it was there that during 1930–35 he persuaded the European governments to embark on regulation of mesh of nets and size limits for fish in the over-fished regions.

This was clearly a man of great and many-sided ability: a critic who shaped irreversibly the course of zoology and of fishery research; a sensible and humane administrator; fond of animals, naturalists and fishermen—he would always help any of them. He led a staff of scientists wisely, teaching us reliance on personality rather than in arrangements, and handing on his own sceptical appreciation that things are rarely what they seem. Would that there were more like him.

MICHAEL GRAHAM

Dr. Jean White-Haney

THE death occurred in the United States on October 21, 1953, of Dr. Jean White-Haney, daughter of the late Mr. E. J. White, one-time assistant government astronomer in Melbourne. She was born in 1877, and after attending the Presbyterian Ladies College entered the University of Melbourne in 1901 to study biology, and graduated as B.Sc. in 1904 and M.Sc. in 1906. She was awarded a McBain Research Scholarship in the same year, and began research in the Botany Department under Prof. A. J. Ewart, at the same time taking University tutorials and teaching science at several schools, including her former one. She was also a University examiner at the public examinations. In 1908 she began full-time research under a grant from the Victorian Government. Between 1907 and 1911 thirteen papers bearing her name were published, eight papers on joint studies with Prof. Ewart and others on the flora of Australia, and also an appendix to his paper on longevity of seeds. In 1909 she was awarded a doctorate of science, being the second woman in Australia to receive this degree, for a thesis entitled "The Ferments and Latent Life of Resting Seed" which was published in the *Proceedings of the Royal Society of London*. Two papers on bitter pit in apples aroused great interest and controversy among horticulturists and staffs of State agricultural departments; the tentative view put forward by herself and Prof. Ewart, that bitter pit could be caused by arsenical spraying, was warmly debated. She was unable to complete the investigation, which was taken over by others under a joint arrangement between Federal and State Governments.

In 1912 she was appointed officer in charge of the Queensland Prickly Pear Board's research station in Dulacca, to initiate work towards eradication of this pest. In this she established the value of arsenical injections and sprays in killing the Dulacca prickly pear (*Opuntia inermis*) and of the wild cochineal insect in killing *Opuntia monacantha*, which was spreading in North Queensland and was afterwards eradicated by the insects. This work was recorded in four reports.

In 1916 she discontinued scientific work, having married Mr. Victor Haney in 1914. She continued to live in Queensland, and was member, and for a time secretary, of the Lyceum Club in Brisbane. In 1928, after further school teaching in Melbourne, she joined the staff of the Council for Scientific and Industrial Research as biological assistant and field officer. While in this position she wrote a history of Australian scientific work on the prickly pear. In 1929 she began a field investigation of the Noogoora burr (*Xanthium pungens*), which was a trouble in sheep pastures in New South Wales, and completed the basic taxonomic studies and survey of its distribution. In 1930 she joined her husband in the United States, and thereafter retired from active scientific work. Apart from one visit to Australia in 1936, she remained in that country until her death.

Dr. White-Haney is remembered by friends and former pupils for her genial personality and the enthusiasm she showed for anything she undertook, and which she succeeded in communicating to others. Several of those whose interest in biology she aroused at school, or at the university, have since made it their life's study. Even after her retirement she maintained an interest in science, and she regretted that the circumstances of her life prevented further active work, and also that she had to leave to others the completion of those investigations that she started.

R. O. TRAILL

Prof. L. J. Stadler

THE death occurred on May 11 of Lewis J. Stadler. Born at St. Louis on July 6, 1896, he received his B.S. degree at the University of Florida in 1917, and his doctorate from the University of Missouri in 1922. After working at Harvard as a National Research Fellow in biology, he became professor of field crops at the University of Missouri. At various times he occupied the position of visiting professor at the California Institute of Technology and that of senior geneticist and later principal geneticist to the Bureau of Plant Industry of the U.S. Department of Agriculture (1930–37).

Prof. Stadler was a member of the Botanical Society of America, the Genetics Society of America (of which he was president in 1938), the American Philosophical Society and the National Academy of Sciences.

His researches were principally in the field of induced mutations in plants, and his important contribution, "The Experimental Alteration of Heredity", published as Chapter 1 in "Science in Progress", Series II, contains the gist of his findings. His work has been of great significance for plant breeding, since the induction of mutations by the use of X-rays, ultra-violet light and other agents is now a valuable technique, which has been the means of effecting valuable improvements in agricultural plants. The *American Scientist* rightly says of him: "A great scientist with a friendly spirit has departed. He will long be remembered for his devotion to scientific research and especially its application to human needs".

S. C. HARLAND

NEWS and VIEWS

Council for British Archæology: Scientific Research Committee

On October 1, the Executive of the Council recommended the formation of a Scientific Research Committee. This is to co-ordinate, and advise on, the applications of scientific research to archæology, to organize and screen the submission of archæological material for expert examination, and generally to act as a clearing house for information and ideas which are of mutual value to archæologists and other scientists. When the Council was formed in 1944, one of its first actions was to consider the many ways in which the natural sciences might be used to interpret and expand the results of archæological field-work. Much, for example, can be learnt of the ecological conditions in primitive settlements from a study of buried soils, peat, pollen and charcoal, while animal bones and even snail shells provide further valuable information about environment in early times. The petrological examination of stone axes, a study already begun by the Council for British Archæology, and the metallurgical analysis of implements and coins also throw light on prehistoric trade and intercourse.

These and other methods of augmenting the results of archæological discoveries were briefly outlined in "Notes for the Guidance of Archæologists in regard to Expert Evidence", published in 1947, which gave details of the facilities then available. The "Notes" are now out of date, not simply in detail, but also with respect to new scientific techniques such as the dating of archæological material by carbon-14 and fluorine content. Developments in science and technology are continually yielding new methods of potential use to archæologists who, in turn, are able to contribute to scientific research by providing accurately dated evidence for the study of metallic corrosion, cellulose degradation, and the earth's magnetic field. To promote further co-operation between scientists and archæologists, therefore, the Council had been considering the establishment of some form of permanent liaison. The proposal was first put forward earlier this year by Mr. L. Biek; and in April, a conference on "Archæology in the Laboratory" was held by the Council, at which scientists of various disciplines were invited to give their views. As a result of the conference, the Executive of the Council decided to recommend the formation of a Scientific Research Committee. Further information may be obtained from the Secretary, Council for British Archæology, 10 Bolton Gardens, London, S.W.5.

National Technical Information Services Officers

The first meeting of National Technical Information Services Officers, organized by the European Productivity Agency of the Organization for European Economic Co-operation, was held at the Department of Scientific and Industrial Research during September 27–October 2. Representatives from the following countries attended: Austria, Belgium, Denmark, France, Germany, Greece, Ireland, Italy, The Netherlands, Norway, Sweden, Turkey and the United States. On September 27 Dr. A. King, chairman of the Productivity and Applied Research Committee of the European Productivity Agency and head of the Intelligence Division of the Department of Scientific and Industrial Research, welcomed the delegates. In the United Kingdom, the Department of Scientific and Industrial Research has been convinced for some time that technical information has an important part to play in the productivity drive; recently attention has been diverted from the mechanics of putting out information to the arrangements made in small and medium-sized firms to use such information. Speaking of the way in which technical information services at the national level can be run, Dr. King said that in the United Kingdom, which has a number of information services, the general policy is decentralization, leaving certain residual and co-ordinating functions to the Headquarters staff of the Department. This arrangement may not be suitable in many O.E.E.C. countries.

At one session of the meeting, 'question and answer' services in the United States, Germany and Great Britain were described, and there was general agreement that such services cannot be organized so that they pay for themselves. It was felt that O.E.E.C. could help by preparation of a paper on how question and answer centres were financed in different countries. As regards the interchange of questions and answers between national centres, it was thought that so far as possible questions should be directed to those countries in which specialized sources of information exist appropriate to the question. O.E.E.C. could facilitate this by treating as urgent the preparation of a guide to specialized technical information services in Europe. The preparation and distribution of technical digests were discussed, and in particular the problem of developing a European digest service was considered. It was thought that the best way of starting such a service would be for the European Productivity Agency to place contracts for the preparation of digests from the national literature in member countries. So far as possible these contracts would provide for the translation of the digests into one of the official languages, and would specify the type and quantity of digests required. In the meantime, the United Kingdom offered to make available copies of the United Kingdom digests at present prepared for circulation within the United Kingdom to any interested national centres. During the conference visits were made informally to the different sections of the D.S.I.R. Headquarters information services, and to the British Productivity Council, the Science Museum, the Patent Office and the Chemical Research Laboratory, Teddington.

Human Relations in Industry

A leaflet, "Human Relations in Industry" (London: H.M.S.O., 1*s.* net), which is being distributed through employers' organizations, trade unions, industrial and professional organizations and other agencies in Great Britain, contains the recommendations and conclusions of a Sub-committee of the National Joint Advisory Council. The Sub-committee concluded that neither the hard facts of Britain's economic and trading position nor the differing circumstances of individual firms are sufficiently understood in industry. The remedy for this does not lie solely within an individual firm, and the Sub-committee accordingly calls for much greater clarity and consistency in government pronouncements on this subject. The Press and other organs which help to mould opinion can also do much more to help by ensuring that what they say is itself informed by a clear and consistent understanding of our national position. The responsibility for achieving good relations is placed primarily on employers, though their efforts can be frustrated unless work-people on their side are ready to understand that any increase in their own real income depends on an increase in the prosperity of the country as a whole, and that an increase in the efficiency and prosperity of their own firms or establishments is an essential contribution to that general prosperity. Employers must therefore accept a responsibility for giving their work-people full and frank information about the fortunes of the firm. Good industrial relations are built on good faith and on mutual respect between employers' and workers' organizations, and the Sub-committee recommends that employers' organizations, nationalized industries and trade unions should increase their activities and those services which will assist in the development of such relations and that their attention should be directed to professional and other associations engaged in this field with the view of encouraging or supporting such work. The leaflet summarizes certain activities, advisory services and training courses in this field and briefly describes the work of the Committee on Human Relations in Industry which has been set up by the Department of Scientific and Industrial Research and the Medical Research Council.

Science in New Zealand

The address delivered by H.R.H. the Duke of Edinburgh before a meeting of New Zealand scientific workers in Wellington on January 13 has been published as Bulletin No. 4 of the Royal Society of New Zealand (pp. 4. Wellington: Royal Society of New Zealand, 1954). After a tribute to the work of New Zealand men of science and to the contributions of New Zealand in scientific development, the Duke said that, although sub-division and specialization are inevitable, the interest of the individual scientific workers need not be lessened by this specialization. The day of the private adventurer in science, however, is over. Even the universities cannot meet the demands of their science faculties and are increasingly dependent on public support. Although in general the public is sympathetic and understands that this is a necessary investment, he continued, the public can only be expected to provide the funds for scientific work for national purposes such as health, agriculture, transport and defence, if it is persuaded that science for itself is a good thing, that scientific workers and their leaders are worthy and that science directly affects conditions of life and work. Those working in science have a duty to help people to understand its various branches and methods and the conditions essential for scientific work, particularly in respect of freedom of thought and investigation and communication. No country can afford to wait for the fruits of scientific research to be handed to her, and New Zealand must herself participate in the search for new knowledge. The Duke thought that the efforts of New Zealand would be best applied to problems now at hand, and that if the right conditions are created New Zealand might expect to foster centres of original scientific work of which she could be proud. In applied research, however, particularly for military purposes, he thought it would be of enormous advantage if the countries of the British Commonwealth could pool their resources. There are not enough workers in any one country of the Commonwealth to provide all the up-to-date equipment necessary to ensure that each unit is properly prepared for a possible war, and he welcomed the creation of the New Zealand Defence Science Corps.

World Population and Resources

Prof. E. P. Stebbing, Romden Castle, Smarden, Kent, in a letter to the Editors, directs attention to what appears to be a serious omission in the PEP broadsheet with this title (see *Nature*, July 3, p. 1) and in the report of the symposium given by members of the executive of the International Geographical Union (*Nature*, June 26, p. 1218). He suggests that the conservation of water supplies is an even more pressing problem than those of finding food, materials, fuel and power for the rapidly increasing world population listed as the most urgent by PEP. In most parts of the world the maintenance of forests over catchment areas to secure an even flow of rivers and to prevent soil erosion and flooding is vital, though financially unproductive in a direct sense. Doubtless the authors of the PEP broadsheet would readily agree that water is the most vital of 'raw materials'; and the International Geographical Union has established a Commission on Arid Lands to study the problem, and its president, Prof. L. D. Stamp, has repeatedly urged that the control of water is the foundation of progress in the under-developed lands, notably Africa. The Food and Agriculture Organization has set up a Permanent European Working Party on the Conservation of Land and Water Resources and has asked all member countries to survey their areas. Unfortunately, no response has been received from the British Government, which indeed has suspended the work of the Inland Water Survey as an economy measure.

J. A. von Segner (1704–77)

A physician who made distinguished contributions to physics and mathematics, Johann Andreas von Segner was born in Pressburg (Bratislava), Czechoslovakia, two hundred and fifty years ago, on October 9, 1704. After studying philosophy at Debrecen, where the Cartesian teachings were still followed, he graduated M.D. at the University of Jena in 1730. Attending the lectures of Georg Erhard Hamberger, professor of medicine, he acquired his lifelong interest in mathematics. In 1733 he was appointed associate professor of philosophy at Jena, and two years later professor of physics and mathematics at the newly founded University of Göttingen, where after the death of J. W. Albrecht in 1736 he was for a time the only professor in the medical faculty. In 1755 he accepted the corresponding chair at Halle. An indefatigable worker and a voluminous writer of dissertations on physics, chemistry, mathematics, geometry and medicine, he introduced a naval barometer in 1743, and in 1750 constructed a water-wheel which bears his name. While he made no original discoveries in medicine, he refuted the theories of the iatromathematical school, establishing mathematics as a handmaiden of medicine. His acquaintance with the principles of Christian Wolf led him to abandon the Cartesian philosophy. Segner's scientific merits were recognized by his contemporaries, for he was created a privy counsellor and was granted letters of nobility by the king of Prussia. He died on October 5, 1777, at the age of seventy-three.

Steroid Reference Collection

The Clinical Endocrinology Committee of the Medical Research Council has been concerned for some time about the supply of reference compounds for work on steroid metabolism. Difficulties have been felt particularly since the introduction of paper chromatography. A few compounds have already been made available through the National Institute for Medical Research, and arrangements are now being made to supply a wider range of steroids. The reference steroids, particularly hormone metabolites, will be provided to recognized laboratories as standards for paper chromatography, colour reactions, infra-red measurements, and mixed melting-points; also, in some cases, as standards for new methods of determination in urine and blood. The preparation of this reference collection has begun, with the help of generous gifts of steroids from industrial firms in Great Britain and overseas. The following firms have contributed materials: British Drug Houses, London; CIBA A.G., Basel; Glaxo Laboratories, Ltd., Greenford, Middlesex; Merck and Co., Inc., Rahway, N.J.; Organon N.V., Oss, Holland; Organon Laboratories, Ltd., London; Parke, Davis and Co., Detroit, Michigan; Syntex S.A., Mexico; G. D. Searle and Co., Chicago, Illinois. Further details and lists of the materials at present available can be obtained from the Medical Research Council, 38 Old Queen Street, London, S.W.1. Requests for materials not listed, and suggestions for other steroids to be added to the collection, should be submitted to Dr. W. Klyne (Postgraduate Medical School, Ducane Road, London, W.12), who is organizing the preparation of the collection. Attempts will be made to find a source or to prepare small quantities of other materials if possible. If workers have other materials which they would be willing to put into the common pool, this would enable the scheme to progress more rapidly. Offers of such materials should be sent to Dr. Klyne. A similar scheme for the provision of reference steroids is already in operation in the United States under the auspices of the United States Pharmacopoeial Convention. It is hoped that it may be possible to arrange for the exchange of samples between the two schemes.

Solar Phenomena recorded at Kodaikanal Observatory

Bulletin Nos. 132 and 134 of the Kodaikanal Observatory embody the results of observations of prominences made at the Observatory during the year 1950. Supplementary data computed from photographs supplied by Meudon and Mt. Wilson Observatories for those days on which Kodaikanal had imperfect or no observations have been included in the bulletins. In addition to the prominences results, the results of magnetic observations made at the Observatory are included in each half-yearly Bulletin, starting with Part 2 of No. 132. The Magnetic Observatory was restarted in January 1949 as part of the post-war development programme of Kodaikanal Observatory, and this was due to the growing importance of geomagnetic observations in relation to solar phenomena and also to the proximity of Kodaikanal to the magnetic equator. Bulletin No. 133 gives the results of a statistical study of the sunspots observed at Kodaikanal during 1903–50, and compares the scheme of sunspot classification suggested by Cortie (*Astrophys. J.*, 13; 1901; and also *Mem. Brit. Astro. Assoc.*, 23; 1921), and Waldmeier's scheme (*Quart. Bull. Sol. Act.*, No. 77; 1947). A discussion of the relative merits of the two schemes leads to the conclusion that, in the absence of necessary arrangements for routine daily observations of the magnetic polarity of sunspots, and the necessity to adopt a scheme of visual classification which covers all the types met with in day-to-day observations (and this conforms to the usually observed life-cycle of the majority of sunspot groups and can be used unambiguously in daily work), Waldmeier's classification is more satisfactory.

The Pacific Islander and Modern Commerce

Under the title "The Pacific Islander and Modern Commerce", the South Pacific Commission has issued as Technical Paper No. 54 (pp. 29. Noumea, New Caledonia: South Pacific Commission, 1954; 2*s*.) a report by V. D. Stace, based on field investigations in Fiji, American and Western Samoa, Papua and New Guinea, including New Britain and New Ireland, Netherlands New Guinea and New Caledonia, during July–October 1952, on the current situation and needs of the indigenous people of the region. The most urgent problem is to deal effectively with the growing desire of these people to participate more effectively in the modern world. The chief conclusions of the investigation are that while improved credit and banking facilities could promote the economic welfare of the indigenous people, at the present stage of their economic and social development, technical and administrative assistance is much more urgently needed. In promoting economic development, the main requirements are incentives, organization and practical education. Village co-operative systems, which modify and rationalize but do not discard the basic elements of the traditional communal methods of organizing production in the Pacific Islands, are more valuable than methods and facilities developed to meet the needs of environments where individualism is the rule and not the exception.

Ethnobotany of Gilbert Islands

Prof. Katharine Luomala, anthropologist in the University of Hawaii, has written in some detail on the ethnobotany of the Gilbert Islands (*Bernice P. Bishop Museum Bull.*, 213, pp. 1–129, Honolulu, Hawaii, 1953). This report affords a useful collation of the available but scattered information about plants of the Gilbert Islands (Micronesia), with special reference to the ethnobotanical aspect in Tabiteuea, based on the author's own observations. The paper gives a general description of the Gilbert group, in terms of location, population, geographical features, climate, domestic plants and animals, etc., and then proceeds to a survey of the sources of botanical information relating to the whole archipelago. Finally, two annotated check lists of plants of the Gilbert Islands are presented: the first groups the plants by families—a comparatively small list; the second list, which occupies some seventy pages, deals alphabetically by local name with all known plants, some of these still awaiting formal botanical identification and naming.

Coryndon Memorial Museum: Report for 1953

The annual report of the Coryndon Memorial Museum, Nairobi, for 1953 (pp. 26+2 plates; from the Museum, Nairobi; 1954; 1*s*.), emphasizes the large amount of cultural activity which can be undertaken by an energetic curator and staff, even in a state of emergency. A fall in income from door receipts has been offset by an increase in certain grants. It is also recorded that the curator, Dr.

L. S. B. Leakey, owing to his special knowledge of the Kikuyu and their language, has devoted much time to duties connected with the Mau Mau disturbances. The year also witnessed the official opening of the new wing by which the exhibition area in the Museum is more than doubled. The extension includes some specially designed screens with paintings of botanical subjects arranged in taxonomic order; habitat groups of coral reef and freshwater and marine fish; a large-scale relief map of the East African Territories; illustrations to explain volcanic formations, rift valleys and river meanders; minerals; Miocene and Pleistocene faunas; and the Hall of Man. A large amount of routine museum work has also been carried out in spite of the extra pressure connected with the new wing.

Growth of Wounded Etiolated *Avena* Seedlings

By using the infra-red image-converter viewing apparatus, C. L. Mer (*Ann. Bot.*, N.S., 18, 157; 1954) has studied the effects of accurately placed localized wounds on the growth of etiolated *Avena* seedlings. It was essential to manipulate and wound the plantlings in complete darkness; the method by which this was achieved is fully described. A hypodermic needle was used for the actual wounding operation. It is shown that the brief exposure to infra-red radiation does not affect the subsequent growth of the plants in darkness. The greatest effect on mesocotyl growth occurs when the node is wounded. A superficial wound in this region reduces growth by 22 per cent; a further reduction of 10 per cent takes place when the vascular system is interrupted. The growth of the coleoptile is also reduced when the node is wounded; the greater part of the reduction is due to the interruption of the vascular bundles. Wounding the plumule also reduces the growth of the seedlings; but the data are considered to be too meagre to warrant drawing firm conclusions. The results indicate that the node is the centre controlling mesocotyl growth.

College of Aeronautics: Awards

THE award of the English Electric Research Fellowship in Aeronautics for the academic year 1954–55 has been made to Mr. M. E. Filby, of 6 Hillview Avenue, Brockworth, Gloucester. Mr. Filby is a former student of Crypt Grammar School, Gloucester, and of Lincoln College, Oxford, where he obtained an honours degree in physics. He is at present a member of the staff of the Research Department of Gloster Aircraft Co., Ltd.

The award of the Perring Scholarship for the two-year course which begins in October 1954 has been made to Mr. G. E. Smith, of 12 Grenoble Gardens, Palmers Green, London, N.13. Mr. Smith was educated at Glendale Grammar School, London, and graduated at the Imperial College of Science and Technology, where he obtained a first-class honours degree in civil engineering.

Pan-African Congress on Prehistory

THE third meeting of the Pan-African Congress on Prehistory will be held in Livingstone, Northern Rhodesia, in July 1955, the provisional dates being July 11–16. During the course of the meeting the centenary will be celebrated of the discovery of the Victoria Falls by Dr. David Livingstone and the beginning of the systematic exploration of the interior parts of the African continent north of the Zambesi. The work of the Congress is at present divided into three sections (though additional sections may be added if deemed necessary), namely: quaternary geology, general palaeontology and climatology; human palaeontology; and prehistoric archaeology. At the meeting, symposia will be held on the Kalahari Sands, their definition, age, distribution and method of formation; the dating of the Australopithecinae; marine strand lines, their definition, altimetric and faunal correlations; the early pebble-tool cultures, their definition, dating and distribution; and the importance and application of the carbon-14 method of dating to African prehistoric cultures. It is also proposed to hold discussions on terminology, research programmes in prehistory and allied subjects in the various African territories, the control of excavations and the care and protection of sites, and the preparation of resolutions on these subjects. A number of excursions have been arranged both to sites of prehistoric remains and to the Victoria Falls, game reserves and other places of natural beauty or general interest. The organizing secretary for the meeting at Livingstone is Dr. J. D. Clark, curator of the Rhodes–Livingstone Museum. All correspondence should be directed to the Organizing Secretary, Third Pan-African Congress on Prehistory, Rhodes–Livingstone Museum, P.O. Box 124, Livingstone, Northern Rhodesia.

International Association of Applied Psychology

THE next Congress of the International Association of Applied Psychology will be held during July 18–23, 1955, in London, plenary sessions being in the Beveridge Hall of the Senate House, University of London, and sectional meetings in Birkbeck College (which adjoins the Senate House). In addition to the opening and closing sessions, four plenary sessions will be held on the following themes: the psychologist and society; the evaluation of methods in applied psychology—the problem of criteria; the relationship between research and practice; and the assessment of attitudes and the relation of attitude to behaviour. Only invited papers, taking up about half the time, will be given at these plenary sessions, the other half being for open discussion. The rest of the Congress will be taken up by meetings at which questions relating to particular aspects of applied psychology—especially educational, clinical and occupational psychology—will be discussed. Members wishing to offer a paper should send a summary of 250 words, before December 31, to the organizing secretary, Mr. Alec Rodger, at 14 Welbeck Street, London, W.1.

Conference on Endocrinology

A WHOLE-DAY conference on "Endocrinology" has been arranged by the Joint Biology Committee and will be held at the County Hall, London, on November 13. The speakers will be Dr. A. E. Stuart Mason, of the Medical Unit, London Hospital, on "Aspects of Endocrinology: Medical Research"; Dr. H. Gardiner-Hill, senior physician at St. Thomas's Hospital, London, on "Endocrinology from the Clinical Point of View"; Dr. T. Mann, of the Molteno Institute of Biology and Parasitology, University of Cambridge, on "Aspects of Endocrinology: the Biological Approach"; and Sir Francis Knowles, senior biology master at Marlborough College, on

"Opportunities and Limitations in the Teaching of Endocrinology at the pre-University Level". The final session will be thrown open for discussion on the points raised by the speakers earlier in the day. Applications for tickets (price 6*s.*) should be made to the Secretary, Joint Biology Committee, c/o British Social Biology Council, Tavistock House South, Tavistock Square, London, W.C.1, from whom further particulars may be obtained.

Exhibition of Kinematography in London

An exhibition of kinematography, comprising films, wall displays and apparatus, will be held by the Kinematograph Group of the Royal Photographic Society in the Society's House, 16 Princes Gate, London, S.W.7, during December 3–18. The exhibition revives an event held regularly before the outbreak of the Second World War. The films will be divided into five sections on the application of kinematography to, respectively, industry, science, medicine, education and other specialized fields. Lectures and demonstrations will also be given. Films for the exhibition may be submitted in any gauge, sound or silent, black-and-white or colour, but the running-time of any one film should not exceed forty-five minutes. It is not essential that films should be the work of one person; they can be made by groups, societies or commercial undertakings. Intending entrants should obtain an entry form as soon as possible from the Honorary Secretary, Kinematograph Group (Exhibition Committee), 16 Princes Gate, London, S.W.7, and return Part 1 of the form, duly completed, as soon as possible. The films, accompanied by Part 2 of the entry form, should be sent in by October 30.

Radio Industry Council Awards

Since January 1, 1952, the Radio Industry Council has awarded premiums of 25 guineas each, up to an average of six a year, to writers of published articles, the object of the premiums being to encourage the publication of articles reporting technical progress and development of radio, television and electronics in Great Britain. The main points to be taken into consideration will be the value of the article in making known British achievement in radio and electronics; the originality of subject; technical interest; and presentation and clarity. Any writer will be eligible who is not paid a salary wholly or mainly for writing and not earning 25 per cent or more of his income from fees for articles or from book royalties. For articles written jointly, each author must be eligible, and the premium will be divided. Papers or periodicals which can be bought by the public on bookstalls or by subscription, at home or abroad, will be eligible, but not journals circulating exclusively to members of a trade, manufacturers' journals, or the privately published journals of professional institutions or learned societies. Entries should be made before December 31 by submitting five copies of the published article to the Secretary of the Radio Industry Council, 59 Russell Square, London, W.C.1.

Announcements

The nineteenth Parsons Memorial Lecture will be delivered at the Institution of Mechanical Engineers by Mr. F. Dollin on October 29 at 5.30 p.m.; Mr. Dollin will speak on "Factors Influencing the Continuing Development of the Steam Turbine".

In connexion with the celebration of the jubilee of the invention of the thermionic valve by Sir Ambrose Fleming on November 16, 1904, a conversazione and exhibition will be held during November 16–18 in the Electrical Engineering Department of University College, London, and a plaque commemorating the occasion will be unveiled by the Lord President of the Council. Admission is by ticket, application for which should be made to the Assistant Secretary, University College, Gower Street, London, W.C.1.

The twenty-eighth annual general meeting of the Bedson Club will be held in the Chemical Laboratories, King's College, Newcastle upon Tyne, on October 15, after which Prof. T. S. Westoll, J. B. Simpson professor of geology in King's College, will deliver a lecture on "Fossils I have Known". Other Bedson Lectures for 1954–55 are: Prof. A. R. Ubbelohde, "Some Physicochemical Studies on π-Electron Compounds" (October 29); Dr. F. G. Mann, "The Comparative Organic Chemistry of N, P and As" (November 12); Dr. R. P. Bell, "The Place of Theoretical Chemistry in Chemical Education" (February 11); and Prof. F. J. W. Roughton, "Rapid Reactions of Hæmoglobin with O_2 and CO" (March 11).

British Celanese, Ltd., announces the award of research studentships in chemistry, tenable for two years from October 1 at the institutions mentioned, as follows: Mr. R. B. Pearson (University College, London), Mr. A. M. North (University of Birmingham), Mr. J. L. Tayler (Imperial College of Science and Technology, London) and R. L. Vale (University of Birmingham).

The Department of Agriculture for Scotland has awarded the following postgraduate scholarships in agricultural subjects, tenable for periods up to three years, commencing in October at the university or centre shown: *Husbandry:* I. C. Beattie, J. Frame, I. A. Munro and Miss S. M. Sweeney (University of Reading); D. C. Graham (University of California); A. M. M. McFarquhar (University of Leeds); Miss M. W. Murray (Ohio State University); W. C. Smith (Massey Agricultural College, New Zealand). The following current awards are being continued for a further period: *Husbandry:* J. Eadie (University of Edinburgh); T. D. MacLean (University of Reading); T. M. Sutherland (Iowa State College); *Agricultural Economics:* A. V. Vickery (Agricultural Economics Research Institute, Oxford); *Agricultural Engineering:* J. Roddan and J. H. S. Torrance (King's College, University of Durham).

A Conference on "Design and Application of Small Digital Computers" will be held at the Bellevue-Stratford Hotel, Philadelphia, during December 8–10. The programme includes papers on computer comparisons, input–output devices, computer systems and characteristics, mathematics, programming, and business and scientific applications. Further information can be obtained by writing to P. O. Box 7825, Philadelphia 1, Pa.

Referring to the communication entitled "Velocity of Electron Pulses" published in *Nature* of August 28, p. 398, the authors write: "We regret we omitted acknowledging the generous assistance of Imperial Chemical Industries, Ltd., which enabled one of us (D. L. R.) to carry on the work in the first year, and the maintenance grant of the Department of Scientific and Industrial Research, for the second year of these investigations".

SOCIAL AND INDIVIDUAL SIGNIFICANCE OF AGEING

THE presence of some five hundred delegates from more than fifty countries in London during July 19–23 for the third Congress of the International Association of Gerontology must be considered an important stage in the gestation of a 'science of ageing' in Great Britain. The three main sections were: (1) Biology and Pathology; (2) Geriatric Medicine and Psychiatry; and (3) Social and Psychological. This report will be restricted to the sixty or more papers in the third section. Dr. J. H. Sheldon in his presidential address stressed the dominance of the social implications of gerontology, and said that "in many countries old age is likely to become the major social problem over the next twenty years". He emphasized the necessity for keeping a sense of proportion, "remembering that those aspects of the therapeutic art which happen to possess greatest technical interest and challenge are not necessarily those of the greatest social importance".

There was considerable appreciation in this third section—though not confined to it—that the major concern should be with the quality rather than the quantity of the later years; that fundamental and applied research should now be directed more towards social and individual adjustments to an already greatly increased expectation of life, rather than to adding still further years to life. A prime objective, as Dr. Sheldon put it, is "so to maintain the general vigour of the old that their capacity to contribute to the common effort and above all to maintain their domestic independence, is retained as long as possible".

The sessions in this third section could be grouped into three main divisions, with the first providing the background. The second such division, here considered as "The Care and Welfare of the Aged and the Ageing", related more to the negative aspects of age, those of atrophy, degeneration and decline, and was concerned with ensuring better provision of medical and social care for those requiring this as a consequence of the infirmities of ageing. These sessions were: "Residential Care", "Integration of Plans for Care in Health and Infirmity" and "Personal Services, Community Activities, Casework and Counselling". The third grouping of sessions took greater cognizance of the positive aspects of ageing, those of growth, development and maturation: "Employment Problems of Older Workers", "Employment of the Elderly" (plenary session), "Experimental Study of Skill in the Elderly" (joint session with Section 1) and "Education for Later Maturity in the U.S.". A general heading here would be "The Utilization of Later Maturity".

Social Policy and Practice

The three main speakers in the first session, "Introduction to Problems of Social Policy", were Prof. A. Sauvy (Paris), dealing with the historical basis of gerontology, Sir Godfrey King, who provided a descriptive analysis of the operation of contemporary provisions for old age in Great Britain, and Prof. E. W. Burgess (Chicago). Prof. Sauvy outlined the three successive ways in which society has looked after its old people—a 'family phase', an 'individualist phase', and a developing 'social phase'. He considered that "the whole problem of old age must be placed on a new basis, or rather it is posed for the first time in an urgent fashion". Sir Godfrey stated that "if in general terms, we define our policy as being an intention to make old age as tolerable and pleasant as we can, many things will have to be done which will call for social decisions of the widest possible character", and that "we have only recently started to give special attention to problems of old age in this country".

Prof. Burgess discussed "The Human Aspects of Social Policy". He laid stress on a need, in planning for the well-being of older persons, for the realization that they "have essentially the same basic values and wishes as all other human beings". A social policy commensurate with the problems of ageing must take this into account—and also "the deteriorating role of older people in modern society". Older people, Prof. Burgess affirmed, have the desire common to others to engage in meaningful activities and to participate in and identify themselves with society: their need for a feeling of security is psychological as well as economic. In "meaningful activities" he included both work and recreation: "the findings of research indicate that work is not solely or even primarily a way of earning a living. It is a way of life by which people regulate and routinize their time, associate with their fellow workers, make use of their skills, gain recognition, achieve status, nurture a feeling of usefulness and find expression in creative activity and in the service of others".

The "Symposium on National Programmes" was not very informative, and it would appear that, strictly speaking, such programmes on age and ageing are not yet in evidence.

Mr. Clark Tibbitts, the chairman of the plenary session, "Critique of Surveys", specified the three areas of inquiry as: general conditions and adjustment of the elderly, their health status, and various aspects of employment of older people. The three papers provided illustrations of these. Dr. M. L. Barron (Cornell) described a nation-wide longitudinal investigation initiated in 1952 to study the effects of occupational retirement and the relationship between health, economic, psychological and social factors in old age; Dr. J. V. Zonnefield reported a medico-social survey of the aged in the Netherlands; and Mr. L. Moss commented on the data from the 1950 Ministry of Labour sample survey on the employment of the elderly. The chairman had pointed out that the primary concern for that session was in survey methods: "are the methods in use satisfactory for getting the kind of information wanted?"

Mr. Moss stated that the main purpose of the Social Survey inquiry was to get "an all-round appraisal of the problem". He gave an account of the rationale of the cross-sectional representative sample survey, showing its relation to detailed inquiries concentrating on one special aspect of a problem. Dr. Barron pointed out that longitudinal studies of the ageing process are better equipped to show relationships between certain factors than are cross-sectional surveys. In his address opening the discussion, Mr. Mark Abrams expressed doubts whether the survey methods in use in Great Britain are fully satisfactory: "we are in danger of merely multiplying our stock of familiar facts". He advocated a considerable widening of the age-span normally considered in old-age surveys, the use here of longitudinal studies of ageing, and also the necessity for a multi-discipline approach: "Hitherto statisticians and medical men have tended to have a monopoly of the planning, direction and interpretation of surveys; research would be more illuminating if their tasks were shared with experts from other fields—sociology, economics, architecture, government and even history".

Care and Welfare of the Aged and the Ageing

There was general agreement among the speakers on the need to prevent any undue increase in the institutional care of the aged. Apart from the shortage of existing hospital and similar accommodation and the mounting social burden involved, Dr. G. Evans, among others, emphasized that it is in the interests of older people that "residential care should be exceptional rather than normal"; main emphasis should be put on preventive work and rehabilitation. But though infirmity was not accepted as a dominant or necessary characteristic of later years, it was recognized that a greater incidence of this must be expected in the final years of life, and also that the increased numbers and proportion of the aged have already made heavy demands on available medical and nursing facilities. Dr. R. C. Walsh spoke of an inadequate response to the problem of the elderly sick and infirm as an "overshadowing challenge" calling for "an imaginative response from health and welfare organizations".

In his paper, "Making the Best of Available Accommodation", Dr. G. W. H. Townsend advocated that hospital beds should "be occupied by the right people and for as short a time as possible" and that "if we are to decrease the demand for beds, every precaution must be taken to see that the aged persons remain self-sufficient or at any rate members of their own family as long as possible". He stressed the value of day hospitals such as that pioneered by Dr. Cosin in Oxford. Dr. Nain Cowen spoke later of the Rutherglen Health Centre for Old People, the chief purpose of which is to keep older people active and healthy at home.

From the chair, Mrs. M. M. C. Kemball had directed attention to a required partnership embracing the family, the voluntary bodies and the statutory services for ensuring the health, care and attention of older people. Various delegates spoke of the importance of enabling the family to make its vital contribution to this partnership and gave accounts of ancillary services and aids provided by voluntary and statutory bodies for this purpose, and to help preserve the independence of the elderly.

Many speakers discussed what is in effect another type of welfare as most appropriate to those not functionally old, that being to allow, encourage and enable them to live substantially normal lives for as long as possible with continued exercise of their capacities and for a fuller development of their personalities over the penultimate period of life. Mr. L. Kuplan's paper, "The Community and the Senior Citizen", was a declaration of the principles basic to this approach, as well as a report of what he described as "an exciting demonstration of democracy in action". He said that, following a State-wide conference on the problems of ageing held in 1951, "the State of California and many of its cities and towns have accepted the principle that the older person must be encouraged and helped to remain an integral and contributory member of the community. Accepted also the corollary principle that the older person must be permitted to live through the later years in self-respect, dignity, security and usefulness". Dr. C. O. S. Blyth Brook, for one, spoke of the sense of service to others as well as the physical and mental exercise involved in suitable employment, as factors checking the conversion of senescence into senility. Dr. J. Weil (Ohio) said "the older person content only with leisure must lose his self-esteem—of purpose for living". The place and purpose of recreation for the well-being of the elderly was discussed by Miss G. E. Bowen (Philadelphia) and Miss V. Ingram (New York). They interpreted its true role as re-creation, so as "to bring the older persons back into the stream of life and help them maintain a maximum of mental health and usefulness" in "an active, creative routine instead of a dull, monotonous one".

Utilization of Later Maturity

"The goals of gerontology must not be viewed as revolving around putting oldsters to work, but to assure that older workers who need work, want work, and who can be fitted for work are given equal opportunities with others to obtain work." In saying this, Mr. A. J. Abrams (New York) had in mind "culture-borne negative attitudes to ageing" as an infringement of democratic, equalitarian concepts. He reported discrimination against older workers as universal, and even evident well before the sixties. He spoke also of initial steps being taken to offset this through job analysis, physical examinations, job counselling, re-training and "re-engineering of jobs to adapt them to ageing workers". An international pooling of data was advocated. But Mr. Abrams felt that, though more technical knowledge is required, there are "enough data already available—so that any country, determined to aid its older workers, need not flounder". Mr. J. A. Scott, in his "Placement of Older Workers", described successful Canadian experiments in older-age counselling. Dr. I. M. Richardson suggested that encouragement and enablement of older workers to go on working efficiently longer than at present is the central problem which would help to solve other problems of old age; but that true preventive measures must be made from the fifties or even earlier.

In his earlier commentary on the 1950 Social Survey, which showed that 23 per cent of the men had retired before sixty, average retiring age being sixty-two, Mr. Moss mentioned that the investigation had also shown no marked difference in the age at which men gave up jobs in different industries and occupations. An implication of this was, he felt, that it was not the actual demands of the job which determined time of retirement but rather attitudes—on the part of the workers themselves and of management. Mr. A. J. Abrams considered that though "oldsters themselves tend to accept the community's image of the older worker", there is a changing of attitudes from retirement, even early retirement, as a life goal. One finding of the British survey was that, at sixty-five years of age and older, much larger numbers of people had stated that they went on working because they preferred to be occupied, irrespective of economic necessity. In a later paper, Mr. J. Roberts dealt with factors in the trade union attitude to this question. He indicated that the principle of "the right to work" is now tentatively being extended to "the right to work for all adults irrespective of age".

Several papers touched on attitudes of employers to the employability of older workers. Mr. Moss felt that in spite of "a limited amount of goodwill" on the retention and taking on of such workers, "the prospects do not appear to be very favourable as long as present attitudes are dominant". Mr. A. J. Abrams mentioned the ineffectiveness of 'exhortation' or even 'proof' for removing age barriers in industry, and the necessity "to motivate top-management to examine personally this problem". "A Report on the Effectiveness of 3,000 Older Workers in a Sampling of American Business Firms" was given by Mr. R. L. Peterson. In this inquiry older workers were evaluated by their immediate supervisors, who used as a comparison "their concept of the average younger worker". The report findings, on those more than sixty years of age, showed "a work volume about the same as for younger workers", as well as less absenteeism, greater reliability and work of better quality. He stated that studies of this kind are influencing American employers to modify their employment programmes.

Mr. A. T. Welford outlined "a minimum programme of research" of an experimental psychological nature on capacities and job demands, which he felt would need to be completed "before a confident policy for employment of older people could be framed". But he pointed out that there are other questions demanding "a method of study which so far has been little used for work on ageing". Examples of these given by Mr. Welford were, "the direct measurement of performance at work on the shop floor and . . . experiments in modifying work to older people". In the joint session, "Experimental Study of Skill in the Elderly", Dr. H. E. Jones (California) observed that "the study of age changes in human abilities has a scientific history of hardly more than twenty years"; Mr. W. T. Singleton pointed out, moreover, that "research in the field of gerontology would appear to have been more concerned with somatic changes than with psychological ones". There were a number of references to the decline of certain mental abilities from a quite early age; but Mme. S. Pacaud (Paris), referring to her experimental studies, emphasized the importance of education as a check on the destructive effects of ageing, and Dr. D. Wechsler (New York) discussed the problems of appraising intelligence in older people; he questioned "whether identical tests identically performed measure the same thing" in this connexion; he also suggested that sagacity or wisdom is an added aspect of intelligence at later years.

Although the papers in the session "Education for Later Maturity" were all contributed by American speakers, a number of other delegates in various sessions stressed the importance of this factor. Three aspects of such education were considered: for personnel concerned with the care of the aged, for the ageing person himself, and for the community in general. Mr. A. J. Carlson discussed the value of adult education in "preparation for the senior years". Mr. O. J. Kaplan, in "Communication of Health Knowledge to Older Persons by Radio and Television", observed that "advances in gerontology have little meaning unless they are reflected in the life and habits of older persons . . . though there was much knowledge already it was misunderstood and unknown by many over 60". Two papers on projects for later-age education were given by Dr. Ruth Andrus and Dr. Wilma Donahue, and Dr. W. H. Reals, speaking on "Programmes for the Ageing in American Universities", reported their rapid development during the past six or seven years. From his surveys, Dr. Reals concluded, "there appears convincing evidence that the problems of ageing and educational provision for the older adult himself have become a definite and increasing concern of universities in the United States".

What would amount to a fourth aspect of 'education' on ageing was indicated by Dr. E. Digby, who questioned "whether there is sufficient thinking together of the biological, psychological and social sides". Miss E. I. Black also, as chairman of this third section, felt that it had a lot to learn from the discussion in the other sections—"but that the traffic should not be one way". This consideration, however, presupposes some evenness in the contribution of research data from the different fields of gerontological inquiry. Though ageing has now become "a major socio-medical problem", it is perhaps significant that there were very few papers of an essentially sociological character in this third section originally specified as "Sociology and Psychology". Dr. Sheldon's comment on "a lack of fundamental thinking in our approach to old age" appears to have a bearing here. In his address, however, Sir Godfrey King had remarked that, with other communities in similar demographic circumstances, "we are now going through a process of adjusting ourselves to the facts". There was an agreement among speakers that research findings from different fields of investigation would need to be taken into account by other specialists if the required unified though multi-aspect science of gerontology is actually to be constituted for the welfare of society.

C. Fleming

BEECH MYCORRHIZA

At the British Association meeting in Oxford on September 3, three papers were read before Section K (Botany) under the chairmanship of Dr. J. L. Harley on the subject of ectotrophic beech mycorrhizas. A great deal of progress has been made in recent years on this subject at Oxford by Dr. Harley and his collaborators: the speakers were pupils of his.

The first speaker, Dr. J. K. Brierley, showed that beech mycorrhizas consisted of a fungal sheath 25–40 μ thick which surrounded a core of host tissue. An account of experiments was given which helped to determine a route by which phosphorus passed through the fungal sheath to the host. He showed that when roots which had been exposed to labelled phosphate were transferred to *phosphate-free* aerated buffer solution, part of the phosphorus accumulated by the fungus during exposure to phosphate is redistributed to the host during the subsequent stage in phosphate-free buffer. Although previous experiments have shown that movement of phosphorus to the host takes place during absorption from an external supply, the experiments described here showed that movement could take place from previously accumulated phosphorus in the fungal tissues to the host in the absence of an external phosphorus supply. Redistribution, as this movement was called, was temperature-sensitive and had a Q_{10} of 2 or greater; it was sensitive to oxygen concentration and became very slow in rate when the oxygen concentration in the washing solution was below 3 per cent.

The observations therefore demonstrated that redistribution was a movement which depended upon metabolic processes and was thus an active transport. It seemed probable that active transport of phosphorus from fungus to host was dependent upon oxidative reactions which occurred in the fungal tissue and perhaps in a lesser degree only upon those of the host. Correlating these laboratory experiments with those made in the field, Dr. Brierley showed that the oxygen concentrations of beech litter, in which mycorrhizas are abundant, were high (about 20 per cent) throughout the year. Hence, under these conditions the rate of active transport to the host would not be impeded and the mechanism was potentially capable of maintaining a steady movement of phosphorus to the host from that accumulated in the fungus.

Dr. Brierley went on to describe experiments which showed that redistribution was diminished in rate when roots were washed in buffer containing phosphate. When roots which had been returned to phosphate-free buffer after a period in buffer containing phosphate, redistribution, temporarily prevented, was resumed at a rapid rate. It was suggested that the phosphate absorbed from the external solution competed successfully with the redistribution mechanism for a substance which, produced in respiratory metabolism, was important for phosphorus transport to the host, so that phosphorus accumulated by the fungus was not mobilized for redistribution. In the absence of external phosphate supply, phosphorus already accumulated into the fungus was utilized and redistribution occurred. Movement of phosphorus into the core was mainly from the external solution when this contained phosphate; but was from sheath phosphorus via the redistribution mechanism when the external supply was stopped. Under natural conditions, fluctuations in available phosphorus must occur, and where supplies of phosphorus were abundant redistribution might be unimportant as a source of phosphorus to the host; but when these supplies failed or became very low, redistribution to the host from phosphorus previously accumulated into the fungus might be of great importance.

In order to further understanding of the role of mineral nutrition in the ecology of beech mycorrhizas, experiments are in progress at Oxford on the uptake of another of the major nutrients, the cation potassium, in contradistinction to the phosphate anion. Mr. Wilson presented the results of some of these essentially preliminary experiments with potassium. Factors affecting the uptake of potassium have been studied by two methods: (1) using an EEL flame photometer measuring differences in K^+ concentration of a solution before and after presentation to the roots; (2) using Rb^{86} and an end-window Geiger counter. The uptakes of Rb^+ and K^+ have been shown to be similar under various conditions, when calculated on a millimolar/milli-equivalent basis.

Uptake of these alkali metals is at least partially metabolic, for sodium azide, iodoacetate, low temperatures (Q_{10} of uptake more than 2), and low oxygen tensions all reduce the uptake of Rb^+, and the last factor considerably reduces the rubidium percentage retained in the fungus. Not only do sodium azide and oxygen tensions less than 5 per cent reduce the uptake of Rb^+ from rubidium chloride, but they also cause a great release of K^+ into both demineralized water and into dilute potassium chloride. Stronger solutions of potassium chloride, however, reduce the net loss of K^+ in the absence of oxygen but increase the loss of Rb^+ in air from roots previously charged with Rb^+; further, the loss of Rb^+ into demineralized water has a much lower Q_{10} than has uptake. These facts indicate that the loss of K^+ and Rb^+ is at least partially a physical process. The Rb^+ accumulation ratio in rubidium chloride of nearly six times in the total absence of oxygen is partially by exchange, for approximately seven times as many milli-equivalents of K^+ are lost as are Rb^+ taken up under similar conditions. This loss of K^+ represents but 20 per cent of the original root content of about 3,000 μgm. potassium/100 mgm. dry weight of roots, of which approximately 45 per cent is in the sheath.

Buffering with sodium phthalate/sodium hydroxide showed that the Na^+ ion depressed Rb^+ uptake. Further experiments demonstrated that Na^+, K^+ and NH_4^+ caused depressions in the Rb^+ uptake of 10, 65 and 32 per cent, respectively, when equimolar with the 0·1 millimolar rubidium chloride solution, and that a depression of 50 per cent was produced by potassium chloride at 0·08 m*M* and by ammonium chloride at 1·8 m*M*, while sodium chloride appeared to be above 10·0 m*M*. Curves of uptake/concentration for the single salts sodium chloride and potassium chloride at the points of equal uptake in μ equivalents provided the ratio $\frac{[Na^+]}{[K^+]}$ in millimoles/litre = 1·3, which is far removed from their relative values as competitors with Rb^+. Further experiments are scheduled to determine the rates of uptake of K^+, Na^+, NH_4^+ in the presence of Rb^+ and of each other, and it is hoped these will clarify the nature of this problem.

Mr. J. S. Waid (now at the Grassland Research Station, Hurley) described the fungi which inhabit the surfaces of beech roots. He outlined a method of sampling fungi inhabiting the surfaces of uninfected roots and ectotrophic mycorrhizas: the method also demonstrated the pattern of colonization of roots by fungi, and confirms some visual observations. Roots were washed in sterile water contained in phials which were mechanically agitated. The water was changed at intervals and after twenty changes the roots were cut into 2-mm. fragments and implanted on nutrient agar plates. Dilution plates were made to determine the number of micro-organisms in the washings and showed that large numbers of sporing fungi characteristic of the 'rhizosphere' were removed from the root region in initial washings and very few in later washings. Microscopical examination showed that propagules were absent upon the surfaces of washed roots, and this evidence, together with that derived from sampling the washings, indicated that only the active mycelia of the root surfaces remained upon the washed fragments.

Examination of the roots of single seedlings showed that different types of fungal infection, including mycorrhizal, could occur on adjacent lateral systems. The population appearing from washed samples of laterals from the same host plant also showed great variation, but the majority of fungi on secondary laterals were non-sporing and a flora of clamp-bearing and sterile mycelia grew from mycorrhizas.

The tap roots bore a less variable but denser population, mainly of sporing fungi, but of different quality from the fungi appearing on Warcup soil plates made with soil from pots in which the plants had grown. Fungi were often absent on growing apices; but as the roots aged the population of fungi appearing on plates increased in numbers and was dominated by sporing fungi.

In another experiment seedlings were grown in beechwood soil but in light intensities ranging from 25·1 to 3·6 per cent daylight. Shading not only resulted in a decrease in the dry weight, free sugar content and the extent of mycorrhizal infection of the seedlings but led also to profound changes in the nature of the surface populations of main and lateral roots. However, these effects cannot be attributed to light alone but to other factors also, such as humidity and temperature.

The numbers of *Rhizoctonia* spp. and *Trichoderma viride* were favoured by decreasing and increasing radiation respectively. *Rhizoctonia*, which is pathogenic to seedlings, was antagonized on the sampling plates by *Trichoderma*, and as the season advanced and mycorrhizas developed, the numbers of the antagonist increased, while those of the pathogen decreased. There was evidence, however, that *Trichoderma* did not entirely determine the numbers of *Rhizoctonia* on the roots. It was indicated that the condition of the host plant plays a major part in determining the nature of its surface flora and that the observations were limited by the fact that a cultural technique was employed which favoured *Trichoderma*.

FIELD BIOLOGY AT THE KING EDWARD VI GRAMMAR SCHOOL, CAMP HILL, BIRMINGHAM

King Edward VI Grammar School, Camp Hill, Birmingham, has recently published a full report by its Natural History Society of a comprehensive survey of a selected area named for convenience Brown's Coppice, the actual name of the principal woodland on the site ("Brown's Coppice: a Survey". Pp. 79. Obtainable from The Secretary, The Natural History Society, King Edward VI Grammar School for Boys, Camp Hill, Birmingham. 5*s*. including postage). The site is about 130 acres in extent, and comprises eight distinct habitats. Forty members of the Society took part in the survey. The studies were divided into nine sections—botany, zoology, ornithology, entomology, edaphic factor, cartography, specialized photography, geography and local history; and a member was appointed to supervise the work of each section. (Later a pond section, devoted to the study of a flooded bomb crater, was added.)

The report is divided into three parts. Part 1 (Physical Features) deals with geography—general and regional setting, relief, drainage and climate; and land utilization—local history and agriculture. This report is commendably thorough, the first chapter being accompanied by six maps and figures and the second by two maps.

Part 2 (Dependent Factors) reports ecological studies—index of habitats, edaphic factor, biotic factor (plant and animal). The habitats included woodland (40 acres), bog (20 acres), pasture (20 acres), hedgerows, standing water (1 acre) and waste land (about 4 acres). This is accompanied by ten maps, transects and quadrats.

Part 3 (Natural History) covers the main groups of the flora and fauna. Twelve pages are needed to list the plants identified, and these are accompanied by six plates. The various fungi, too, are listed. Some good work in bacteriology is also reported, and this is of particular interest since the subject usually receives such scant treatment in schools. Similar detailed treatment is afforded to the fauna, including invertebrates and mammals; separate chapters are devoted to insects and birds. Further plates illustrate a giant puffball, two birds, a photomicrograph of a blow-fly and one of *Cyclops*.

Three appendixes complete this report, which is the most comprehensive and thorough of its kind which we have seen produced by a school. King Edward VI Grammar School, Camp Hill, Birmingham, is to be congratulated on a very worthy effort.

COMPARATIVE PERFORMANCE OF NICKEL AND POROUS ALUMINA SAMPLE HOLDERS FOR DIFFERENTIAL THERMAL ANALYSIS

During a comparative evaluation of the performance, under identical conditions, of porous sintered alumina and nickel specimen holders for use in differential thermal analysis, it was observed that for certain reactions involving the evolution of a gas, such as the thermal decomposition of a calcium hydroxide ($Ca(OH)_2$) and calcium carbonate ($CaCO_3$) and mixtures of these two compounds, the significant linear portion of the downsweep of the peak occurred at appreciably higher temperatures when using a nickel block than when using an alumina block of identical dimensions. The cylindrical sample holders used were 41 mm. high and 38 mm. in diameter, with sample wells 13 mm. wide and 19 mm. deep. A linear heating rate of 15° C. per min. was employed.

The curves obtained using the two types of sample holder are superimposed to facilitate interpretation (Fig. 1). The peak displacement observed is illustrated in curve 1 for a calcium hydroxide–calcium carbonate mixture, and in curve 2 for pure calcium carbonate.

This anomaly could not be accounted for by considerations of thermal conductivity or heat capacity, and it was also found that the peaks due to phase-changes such as the α–β quartz transformation[1] and the rhombic–trigonal inversion in strontium carbonate[2] showed no such displacement. This suggested that loss of gas in the decomposition of calcium hydroxide and carbonate might be responsible for the anomaly, in that the pores in the alumina sample holder permitted the escape of the gaseous decomposition products, lowering the concentration of the gas in the mass of sample, and so leading to the more rapid completion of the reaction. Following the reasoning that if the porous alumina block could be rendered impermeable to gas this effect would be eliminated, thin impervious linings of vitreous silica were fitted to the sample wells in the alumina block. In this modified block, the anomaly disappeared, as shown in curves 3 and 4, respectively, for calcium hydroxide and calcium carbonate. Bearing in mind

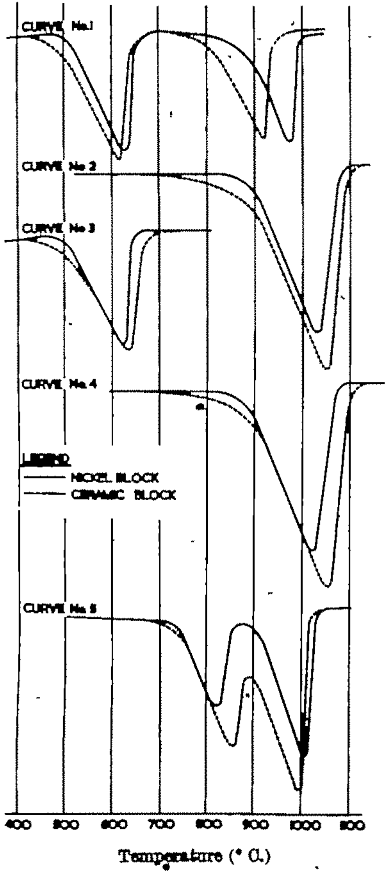

Fig. 1

that in a static atmosphere the thermal decomposition of magnesite appears to be virtually independent of carbon dioxide pressure[3], and according to Stone[4] even in a dynamic atmosphere considerably less dependent than calcite on carbon dioxide pressure, thermal analyses of magnesite were carried out in the unsleeved alumina block and the nickel block. No peak displacement was found, confirming the explanation postulated above. Arising from the report by Haul and Heystek[5] that while reduction of the carbon dioxide pressure in the furnace atmosphere has no effect on the position of the first dolomite peak, it displaces the calcium carbonate peak downwards, determinations on dolomite in both the unsleeved alumina and nickel holders were carried out. These yielded the thermograms shown in curve 5, in which the coincidence of the significant portions of the first peaks, and the downward displacement of the calcium carbonate peak in the thermogram obtained using the porous holder, can be clearly seen, affording further confirmation.

The fact that the displacement of the calcium carbonate peak in the calcium hydroxide–calcium carbonate mixture is far greater than in pure calcium carbonate (curves 1 and 2) is accounted for by the same factor. In the mixture, after the hydroxide has decomposed, the resulting calcium oxide undergoes an exothermic solid-phase reaction[6] with the carbon dioxide produced in the initial stages of the decomposition of the carbonate, particularly in the hotter peripheral parts of the sample well. This exothermic reaction masks the earlier part of the endothermic decomposition of the calcium carbonate by cancellation. This effect is much more pronounced in the impervious walled nickel specimen holder than in the porous alumina cell, where much of the carbon dioxide produced is lost by diffusion.

This effect has also been observed in samples of calcium hydroxide compacted to very different densities in the nickel sample holder; as the density increases, with a consequent decrease in porosity, the peak is displaced to a higher temperature, as much as 20° C. for a change in sample bulk density of 100 per cent.

These observations illustrate the need for standardization of sample holders, the bulk density and porosity of the thermo-active material and also the geometry of the sample well as pointed out by Arens[6].

The comparison of the two types of sample holder has also shown that for endothermic reactions such as the decomposition of calcium hydroxide, calcium carbonate and magnesium carbonate, the nickel block is only slightly less sensitive than a ceramic holder. At temperatures of about 500° C., it gives peak areas which are about 80 per cent of those for the ceramic block and at about 900° C., about 70 per cent. The nickel holder yields peaks which are sharper (that is, they have a greater amplitude in relation to their width) and it also has greater resolving power (hence closely adjacent peaks can be more clearly differentiated), as illustrated in curve 5. This effect is partially due to the more definite point of inflexion on the curve where it first leaves the base-line in thermograms obtained using the nickel block. This characteristic is most clearly shown in curves 3 and 4. The fact that it also occurs in the thermogram for magnesite shows that this effect is not due to porosity. It is ascribed to the higher thermal conductivity of the nickel holder, a factor believed to operate as follows. Endothermic decomposition commences in those portions of the sample nearest the walls of the sample well, and, in the case of the nickel holder, heat is readily available from the large mass of metal of high conductivity in contact with the cooler decomposing material. Rapid heat-flow into this superficial layer masks the early part of the reaction by neutralizing the endothermic effect before it can affect the differential thermo-junction. It is for this reason that the endothermic reaction appears to start at a higher temperature in the nickel holder. When the temperature reaches a value at which the rate of decomposition becomes so rapid that the heat from the nickel can no longer penetrate the increasingly thick layer of decomposed material of low thermal conductivity sufficiently rapidly to neutralize the endothermic effect, the reaction quickly manifests itself, reaching, for the rest of the decomposition period, a rate comparable with that prevailing in the ceramic holder.

Under identical and closely controlled experimental conditions, the variations in all the significant parameters for the calcium hydroxide peak were lower in thermograms obtained using the nickel sample holder, namely, about 1 per cent compared to 2 per cent in the case of the peak areas. The temperature difference between the furnace atmosphere and the centre of the inert reference material is smaller in the nickel holder than in the ceramic, varying from respectively 25 and 40° C. at 100° C., through 11 and 28° C. at 500° C. to 4 and 12° C. at 1,000° C.

A full account of these and related findings will be published elsewhere. This communication is published by permission of the South African Council for Scientific and Industrial Research, and acknowledgment is made to Mr. J. E. Kruger for assistance in this work.

[6] Arens, P. L., Ph.D. thesis, Landbouwhogeschool, Wageningen (1951).

Somewhat similar experiments to those described by Mr. T. L. Webb have recently been carried out, quite independently, at the Macaulay Institute for Soil Research; but clay minerals were used for all comparisons. Porous sintered alumina and nickel specimen holders with cylindrical sample-wells and of identical dimensions, conforming to those previously described for the same apparatus[1], were used; in addition, the nickel holder could be fitted with a lid. The results corroborate those of Mr. Webb; but as they are somewhat complementary and additional observations were made, a brief note upon the findings seems desirable.

The curves obtained for the main endothermic peak of kaolinite (the 'standard' sample used for differential thermal analysis standardization[2]) using the porous alumina specimen holder, the nickel specimen holder, and the nickel specimen holder with lid are shown superposed in Fig. 1. The difference between the curves for the porous alumina and nickel holders is similar to that described by Mr. Webb for calcium hydroxide, and previously reported by Gérard-Hirne and Lamy[3] for kaolinite; namely, using the nickel holder, the peak is smaller (about 75 per cent the area of that in the alumina holder), the peak temperature is higher by about 6° C., and the peak is sharper and apparently becomes more asymmetric. The apparent asymmetry is not, however, reflected to any extent in the 'slope ratio'[4], which for both curves is approximately 1·12. Additional confirmation of Mr. Webb's hypotheses regarding the effects of nickel specimen holder upon thermal peaks is afforded by the curve for the nickel specimen holder fitted with lid (Fig. 1). This both reduces the ease of diffusion of gaseous products away from the sample and provides an additional nickel surface in contact with the sample. Comparing the curve with that for the nickel specimen holder without lid, the expected features are observed; namely, using the lid, the peak area becomes slightly smaller (about 90–95 per cent of that without the lid), the peak temperature is higher by about 10° C., the peak is somewhat narrower, and the asymmetry increases (slope ratio about 1·30). This asymmetry would, of course, be expected because of the more rapid heat conduction into the sample from nickel than from alumina while the specimen is returning to normal base-line conditions.

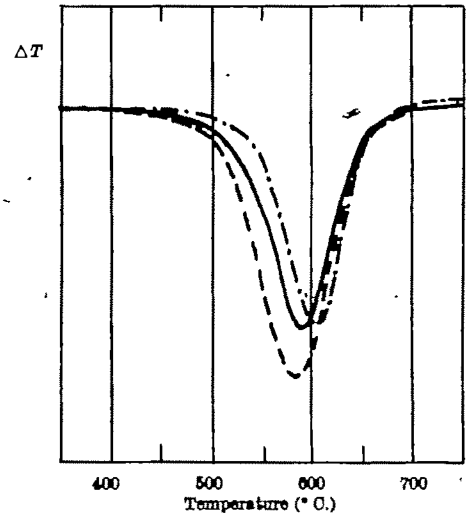

Fig. 1. Thermograms for the main endothermic peak of kaolinite in a porous alumina specimen holder (– – – –), a nickel specimen holder (———), and a nickel specimen holder with lid (—·—)

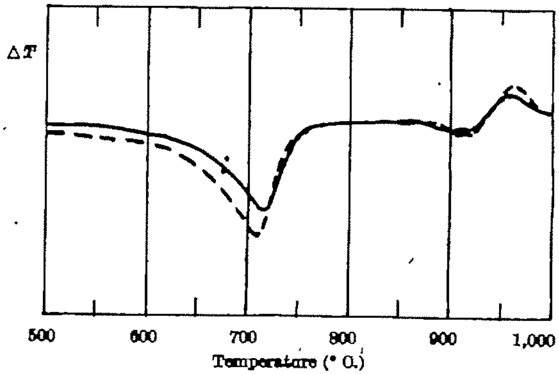

Fig. 2. Thermograms for montmorillonite (Wyoming bentonite) in a porous alumina specimen holder (– – – –) and a nickel specimen holder (———)

There currently appears to be some confusion regarding the magnitude of exothermic peaks in nickel and alumina specimen holders; Arens[5] has claimed that exothermic peaks are smaller in ceramic specimen holders than in nickel, while Gérard-Hirne and Lamy[3] report the opposite effect. The exothermic peaks for the kaolinite samples examined in the above experiments were not particularly suited for measurements of this nature, but some experiments were carried out with Wyoming bentonite (montmorillonite), which gives a much smaller exothermic peak (Fig. 2). In the nickel specimen holder (lid off) the exothermic peak is smaller than in the alumina specimen holder in about the same proportion as the endothermic peak is smaller. This finding agrees with that of Gérard-Hirne and Lamy but not with that of Arens; it does, however, appear to conform with the different characteristics of the two holders, the heat of reaction being conducted away from the surface layers more rapidly in the nickel specimen holder.

The marked difference in position of base-line in the region below 600° C. in Fig. 2 is easily explained. After the removal of the lattice hydroxyl groups the sample has different heat characteristics and the base-line appears at a higher level. As would be expected, this displacement is larger for the alumina than for the nickel specimen holder, and as the latter parts of the base-lines are superposed the earlier parts appear at separate levels. The same effect may be observed on Mr. Webb's curve 1, where the base-lines for the earlier parts of the curves are superposed and the two curves separate after the calcium carbonate peak.

That some of the above observations appear to be at variance with those of Arens may in effect be somewhat illusory. So many experimental factors are involved that each set of results can only strictly apply to the particular apparatus upon which they were obtained, and a rigorous comparison requires a critical survey of all available data, as well as a knowledge of the theoretical implications of the many factors concerned.

In spite of the various apparent advantages of the metal specimen holder, rigid standardization upon this type seems scarcely desirable. For example, while a metal holder is very suitable for dolomite determinations, we have found an alumina holder of low porosity gives reasonable results. For some investigations, indeed, the alumina type may be preferable; for example, the loss of 25 per cent in peak area may in certain circumstances be quite serious and not offset by increased sharpness of peak. The choice of holder, therefore, is logically related to the problem involved. On the other hand, the contributions of Arens[5] and Stegmüller[6], taken in conjunction with theory, may eventually make standardization of the geometry of the sample well, as suggested by Mr. Webb, possible. Uniform tightness of packing of specimens is more desirable and is relatively easy to obtain provided one operator performs all comparative tests; whether it can, however, be attained by two operators independently without use of elaborate apparatus is open to doubt.

In conclusion, I am grateful to Mr. Webb for sending me a copy of his note before publication, and should like to express my thanks to Mr. D. J. Greenland and Mr. U. Schwertmann for carrying out the actual determinations involved.

FREE RADICALS IN BIOLOGICAL MATERIALS

By PROF. BARRY COMMONER, JONATHAN TOWNSEND and GEORGE E. PAKE

Henry Shaw School of Botany and the Department of Physics,
Washington University, St. Louis, Missouri

THE chemical activity of living cells is usually ascribed to compounds which are ordinary molecules, all the electrons of which occur in pairs. However, one of the striking results of efforts to analyse the reaction mechanisms of biological processes is the frequency with which it becomes necessary to depart from this rule. Investigation of a number of important biological processes leads to the conclusion that free radicals, that is, compounds with one or more unpaired electrons, occur as reaction intermediates.

Free radicals have been implicated as decisive participants in (*a*) biological oxidation-reductions[1,2], (*b*) the action of ionizing, ultra-violet and visible radiation on biological systems[3], (*c*) chemical carcinogenesis[4].

Although these inferences, if correct, are of far-reaching importance, all have been derived from indirect evidence and model experiments; free radicals have not been demonstrated in living things. From the fact that many free radicals are notoriously unstable, it has been supposed that free-radical intermediates formed during a biochemical process would be short-lived, and incapable of contributing to the more or less permanent components of the cell.

Until recently, the methods available for investigating free radicals were not suited to work with biological materials. This deficiency has in part been rectified recently by the development of paramagnetic resonance absorption techniques which are capable of detecting small amounts of free radicals in the presence of the large amounts of diamagnetic substance which occurs in living material. The present communication reports investigations based on this new technique. The results show that free radicals occur in plant and animal tissues, and provide evidence relating free radicals to metabolic activity and certain photochemical processes. Contrary to expectation, it has been found that some biological free radicals, such as melanin, are extraordinarily stable.

Paramagnetic resonance absorption is due to the unpaired electrons associated with free radicals. Experimental techniques and apparatus for detecting it have been described elsewhere[5]. Biological material is lyophilized and the resulting powder inserted into the absorption chamber of the apparatus. Typical results are illustrated in Figs. 1 and 2. The area under the absorption curve is proportional to the number of unpaired electrons in the sample, and the free-radical content of biological materials may be evaluated in this manner.

Table 1 lists the estimated free-radical content of a number of tissues. Certain significant differences are apparent. Most notable is the high free-radical content found in metabolically active tissues, such as the green leaf, liver and kidney. The extraordinarily high value of frog eggs is due to the presence of melanin, which is a free radical. The paramagnetic resonance absorption of lyophilized tissue persists for months under refrigeration.

Fractionation experiments show that the paramagnetic resonance absorption generally found in tissues is associated with protein components and

Table 1

* These values are based on comparison of the absorption given by approximately 0·5-gm. samples with the absorption given by 10^{-8} mole of diphenyl picryl hydrazyl free radical under identical instrumental conditions.

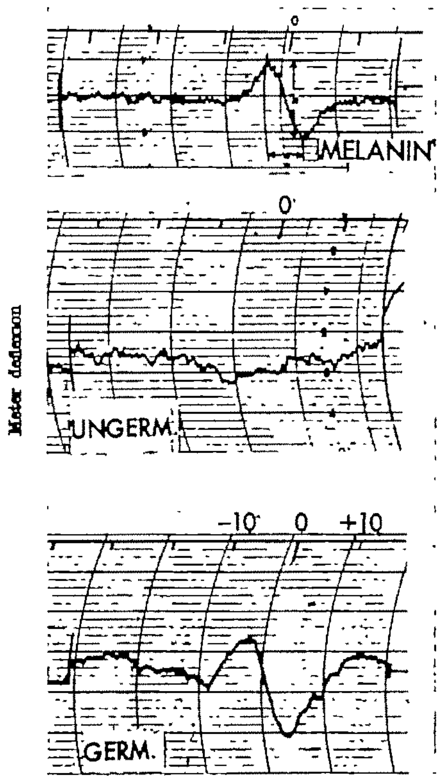

Fig. 1. Paramagnetic resonance absorption given by 1-gm. samples of lyophilized digitalis seeds before germination, and just after emergence of the primary root. Magnetic field increases towards the right along the abscissa, with point marked zero representing position of paramagnetic resonance absorption given by a standard free radical, diphenyl picryl hydrazyl. Ordinate represents the rate of change, with respect to field strength, of microwave energy (9,000 Mc./sec.) absorbed by the sample, as the field-strength is varied

For comparison, the uppermost curve shows the paramagnetic resonance absorption given by a stable free radical (melanin). The presence of unpaired electrons associated with the free radical results in absorption of incident microwave energy when the varying external magnetic field reaches about 3,000 gauss (point marked zero). The apparatus records the derivative of the absorption curve, and free radical content can be estimated from the quotient $h \times w^2$

that denaturation of the protein destroys the free radicals.

In the light of the suggestion of Michealis[1] and others that free radicals occur as intermediates in biological electron-transfer processes, it is of considerable interest to investigate the association between free radical content and metabolic activity. We find that initiation of active metabolic processes in dried yeast preparations increases the free-radical content significantly. There is similar evidence that free radicals are formed as a result of the increased metabolic activity induced by germination of seeds (Fig. 1).

Etiolated barley leaves show only about one-fifth the paramagnetic resonance absorption observed in fully green leaves. Fig. 2 shows that when etiolated leaves are exposed to 100 ft. candles of illumination from fluorescent lights, the original paramagnetic resonance absorption increases remarkably within six hours. After 24 hr. of illumination, during which time the leaves become fully green, it reaches the magnitude observed in normal light-grown leaves. Thus, the large paramagnetic resonance absorption observed in the green leaf is a result of photochemically induced formation of free radicals. This process may be associated with the synthesis of chlorophyll, for Smith[6] finds evidence that a free radical may occur as an intermediate in the photochemical conversion of protochlorophyll into chlorophyll. Preliminary investigations have been carried out to determine whether the paramagnetic resonance absorption of fully green leaves changes during illumination. The results obtained thus far show that such an effect, if it exists, must be small. The above data tend to support Michealis's proposal[1] that metabolic electron transfer induces the formation of a small steady-state concentration of free radicals.

The occurrence of paramagnetic resonance absorption in melanin suggested that similar polymeric products of biological origin be examined for free radicals. A series of natural products of this type have been studied. Paramagnetic resonance absorption has been detected in the following: gum guaiacum, liquorice (powdered root of *Glycyrrhiza*), humin (from protein hydrolysis), various plant resins, caramelized glucose, charcoals of organic origin, various types of coal and tars. The free radicals associated with these products all appear to be indefinitely stable at room temperature, and a number resist heating. The paramagnetic resonance absorption of melanin resists 24 hr. of refluxing in hydrochloric acid.

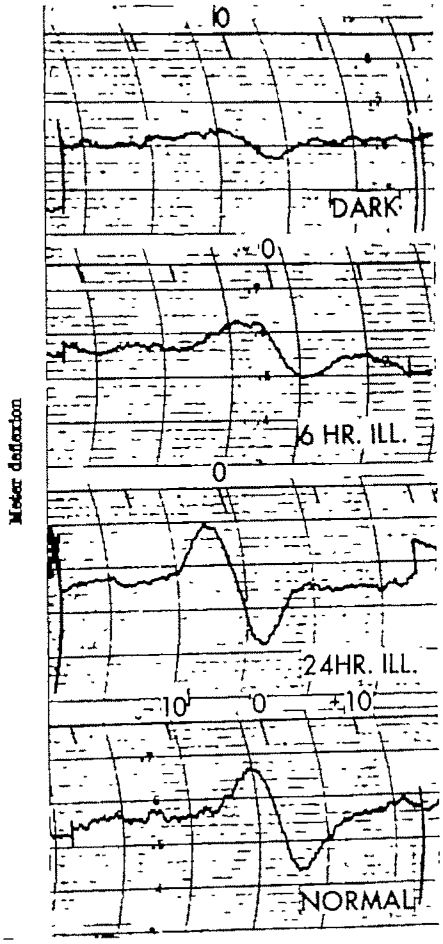

Fig. 2. Paramagnetic resonance absorption of 0 65-gm. samples of leaves from barley seedlings Uppermost curve. etiolated. Lowermost curve. leaves from comparable seedlings grown in light. Centre curves etiolated leaves after 6 and 24 hr. of illumination Ordinate and abscissa as in Fig. 1

Despite their apparent heterogeneity, the natural products containing unpaired electrons have a characteristic in common: all these materials contain polymeric condensed ring structures. The plant products listed above are all highly polymerized condensed ring structures. The same is true of melanin. Recent investigations on the structure of coal[7] show that condensed ring polymers resembling the graphite structure constitute a large portion of the material. These polymeric aggregates apparently account for the roughly spherical particles, about 0·05 μ in diameter, which are seen in electron micrographs of ethylene diamine extracts of coal[8]. We find distinct paramagnetic resonance absorption in such coal extracts. It is likely that similar aggregates also occur in tars, caramels and other organic materials which have been carbonized by heat or by other means.

It is suggested that unpaired electrons generated during reactions which lead to these condensed ring products (that is, melanin, gums, resins, coal) become trapped and stabilized in the polymer lattice. Similarly, unpaired electrons resulting from carbonization by heat, or by strong acid, may become incorporated into the graphite-like aggregates which are formed. That such polymers have a high affinity for unpaired electrons, and thereby form stable free radicals, is to be expected from recent observations that the electron affinity of a series of condensed ring substances increases considerably with the size of the molecule[9].

While these preliminary observations do not offer an explanation for these phenomena, they do show that unpaired electrons may occur in highly stable configurations in substances of considerable biological interest.

These results show that tissues contain two types of free radicals: (*a*) tissues possess free radicals apparently associated with protein moieties, which are heat-labile, occur in the concentration range of 10^{-4}–10^{-6} mole of free radical per gm. of tissue, and which appear to increase in amount during metabolic activity; (*b*) a number of polymeric condensed-ring substances, such as melanin, which are characteristic products of certain organisms, contain unpaired electrons in a highly stable configuration.

Certain broad conclusions can be derived from these observations. The properties of the labile free radicals which we have detected are consistent with Michealis's characterization of the free radicals generated by oxidative metabolism: (*a*) they appear to be associated with proteins; (*b*) they attain concentrations which vary with the level of metabolic activity; and (*c*) the range of free-radical content, 10^{-4}–10^{-6} mole/gm. of tissue, is of the order of magnitude expected from McIlwain's estimation[10] of the total electron carrier content of tissues (10^{-4}–10^{-6} mole/gm.). Furthermore, measurements of paramagnetic resonance absorption confirm the suggestion[1] that electron carriers such as riboflavin and pyocyanin are capable of forming free radicals. While these observations do not constitute proof of Michealis's proposals, they do provide both incentive and experimental opportunities for more intensive investigations of this problem.

The discovery of unpaired electrons in melanin is indirect evidence that free radicals are formed by irradiation of biological systems, for it has been shown that melanin formation in animals may be induced by ultra-violet and ionizing radiation[11]. Paramagnetic resonance absorption induced by illumination of etiolated leaves is direct evidence for such an effect.

The discovery that certain common biological products are extraordinarily stable free radicals raises a number of intriguing questions concerning the physical chemistry of substances such as melanin and resins, and also poses problems of concern to the biologist. If the unpaired electrons in such polymers are not continuously accessible to the reaction mechanisms of the cell, these substances can be thought of as dumping grounds for unpaired electrons. In this case they may influence the course of cellular metabolism by irreversibly removing unpaired electrons generated by oxidation-reduction or photochemical processes. In this connexion the induction of melanin formation by ultra-violet or ionizing radiation may be construed as a protective mechanism which, by sequestration of photon-generated unpaired electrons in an inactive configuration, forestalls more violent effects of irradiation on the cell. An alternative approach would be required if it is found that the unpaired electrons in condensed ring polymers react readily with metabolic components of the cell. This would suggest the possibility that electron transfers between metabolic intermediates may take place by a quasi-metallic conduction of electrons through the intervening condensed ring structures. From this point of view it is significant to note that the wave function of an unpaired electron associated with a condensed ring molecule appears to extend throughout a region which encompasses most of the structure[12]. The electron may therefore be considered to be highly mobile within the structure, and thereby capable of mediating conduction within it. This proposal would become especially important if it were found that enzyme proteins are capable of holding stable unpaired electrons. Such an observation would support Szent-Györgyi's suggestion[13] that cellular oxidation-reduction processes involve electron-transfer through a protein continuum.

We are indebted to Mr. James A. Warnhoff for assistance in conducting these investigations, and to Dr. S. I. Weissman for many helpful discussions of this material.

Synthesis of Sucrose by a Partially Purified Plant Tissue Extract

It was reported previously[1] that a crude extract obtained from peas formed sucrose when incubated with a mixture of glucose-1-phosphate and fructose. Evidence was presented that the sucrose synthesis was not due to a simple reaction between glucose-1-phosphate and fructose as catalysed by bacterial sucrose phosphorylase[2]. In the present communication the results of some experiments with a partially purified pea extract are briefly described. Since this work was carried out, Leloir and Cardini have reported[3] the extraction from wheat germ of an enzyme which catalyses the reaction

$$\text{uridine diphosphate glucose} + \text{fructose} \rightleftharpoons \text{sucrose} + \text{uridine diphosphate.}$$

It is probable that this reaction is the final step in sucrose formation from glucose-1-phosphate and fructose by pea extracts.

The partially purified extract was obtained by the addition of ammonium sulphate (to 80 per cent saturation) to the crude pea extract, suspension of the precipitate in water and subsequent dialysis against 0·025 M phosphate buffer of pH 7·0 at 4° C. No sugars or phosphoric compounds (other than inorganic phosphate) were detected when trichloracetic acid extracts of the preparation were examined on paper chromatograms.

This dialysed extract, unlike the crude extract used previously, did not synthesize sucrose from glucose-1-phosphate and fructose; but this activity could be restored by the addition of the boiled crude pea extract. The dialysed extract was stable for two days at 4° C. and for seventeen days at – 15° C.

The addition of magnesium chloride to enzymic digests containing the dialysed extract, glucose-1-phosphate, fructose and boiled crude pea extract was found to increase sucrose formation. No sucrose was formed with magnesium chloride unless boiled crude pea extract was added. It was therefore concluded that the boiled crude pea extract contained a factor or factors, other than magnesium ions, essential for the synthesis of sucrose.

The boiled crude pea extract could be replaced by nucleotide fractions prepared from peas or yeast. Peas (or yeast) were extracted with hot aqueous alcohol, the nucleotides precipitated with mercuric acetate and the precipitate decomposed with hydrogen sulphide in the cold. The mercuric sulphide was filtered off and the filtrate aerated and neutralized to pH 7·0. No free sugars were detected in these nucleotide fractions when samples were examined on paper chromatograms.

The formation of sucrose from glucose-1-phosphate and fructose in the presence of the dialysed pea extract, yeast nucleotide fraction and magnesium chloride is shown graphically in Fig. 1. After 41·6 hours, fructose had decreased to nearly zero, and the loss of this sugar was approximately 4·5 times that required to account for fructose appearing in the sucrose formed. The progress of the reaction is also shown in the chromatogram in Fig. 2. It has been possible to prepare in crystalline form a sample of sucrose, which must have been synthesized since none was present in the dialysed extract or nucleotide fractions.

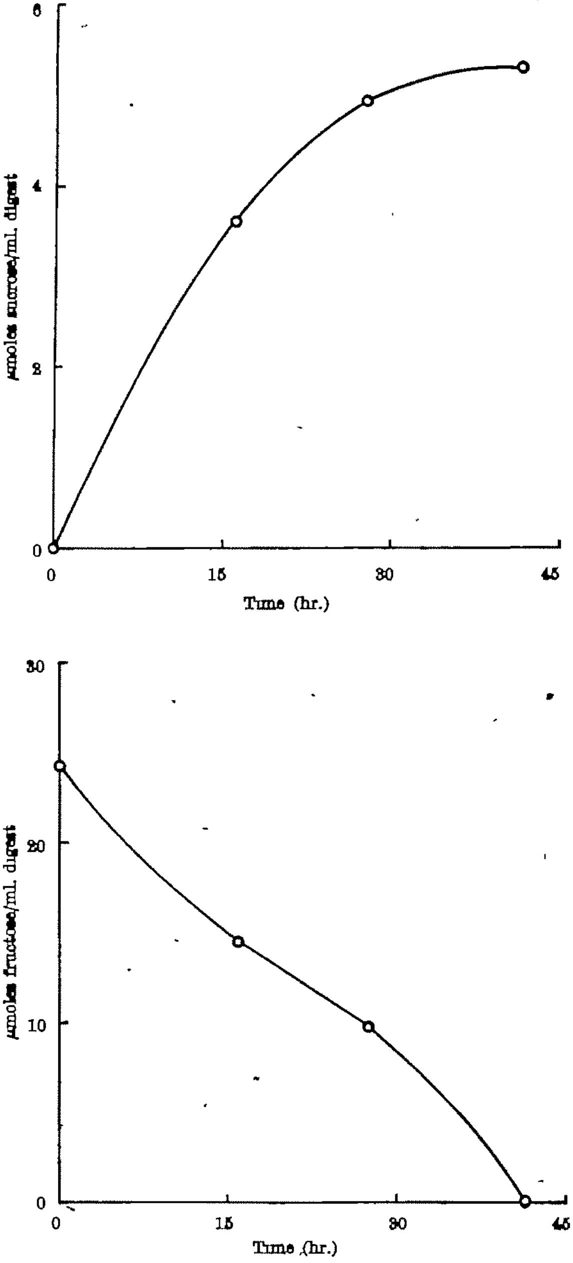

Fig. 1. The formation of sucrose and the loss of fructose in a digest containing the dialysed pea extract. Digest: glucose-1-phosphate, 0·0144 M; fructose, 0·0244 M; MgCl$_2$, 0·01 M; yeast nucleotide fraction, 0·5 ml.; dialysed pea extract, 1 ml.; total volume, 1·8 ml. pH 7·0, 25° C.

It was found that in enzymic digests containing the dialysed pea extract and the nucleotide fractions, *less* inorganic phosphate was liberated when fructose was added than with glucose-1-phosphate alone as substrate. As already reported, the addition of fructose to digests containing the crude pea extract and glucose-1-phosphate produced an increased liberation of inorganic phosphate[1].

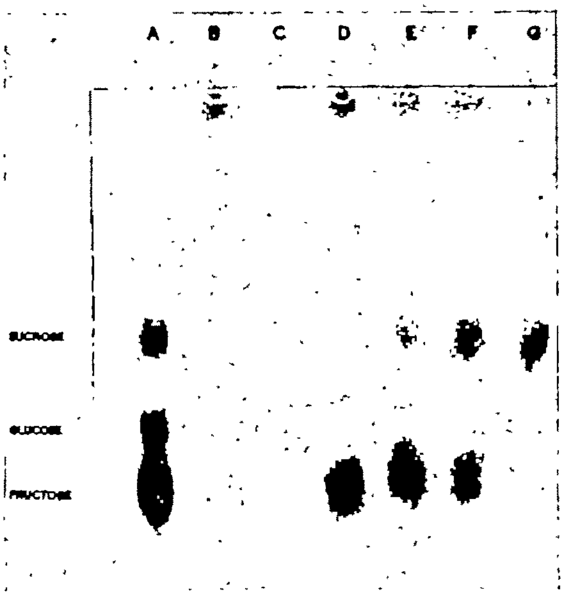

Fig 2. Chromatogram of sugars showing formation of sucrose by the dialysed pea extract. Digest as in Fig. 1. *A*, solution containing sucrose, glucose and fructose; *B*, *C*, digest without fructose after 1 min. and 41·6 hr. respectively; *D*, *E*, *F*, *G*, digest with fructose after 1 min., 16 hr., 27·6 hr. and 41·6 hr. respectively. Whatman No. 1 paper. Solvent, *n*-propyl alcohol (80 vol.)/water (15 vol.)/ammonia (5 vol.). Running time, 18 hr. $AgNO_3$–NaOH spray (ref. 4)

Sucrose synthesis was decreased when the enzymic reaction was carried out in the absence of oxygen. In an atmosphere of nitrogen, synthesis was inhibited by 81 per cent; *in vacuo* the inhibition was 86 per cent.

Glucose-1-phosphate could be replaced by glucose-6-phosphate or fructose-6-phosphate as substrate for sucrose formation. This was to be expected as the pea extract contained phosphoglucomutase and phosphohexoisomerase. As the extract also contained amylose phosphorylase, starch (plus inorganic phosphate) was able to replace glucose-1-phosphate. Fructose could not be replaced by fructose-1-phosphate, fructose-6-phosphate or fructose-1,6-diphosphate.

The coenzyme activity of the pea and yeast nucleotide fractions was acid-labile and the effect of heating with 0·1 *N* hydrochloric acid suggested that diphosphopyridine nucleotide might be involved. Factors which were more acid-stable were also present. In subsequent experiments it was found that the nucleotide fractions could be replaced by a mixture of diphosphopyridine nucleotide, uridine monophosphate and adenosine triphosphate.

Several experimental results, including the requirement of diphosphopyridine nucleotide and adenosine phosphates, the esterification of inorganic phosphate and the formation of fructose-1,6-diphosphate and carbon dioxide by the enzymic digests, are readily explained if it is assumed that a glycolytic system was operating during sucrose formation.

It has been suggested that free hexoses are not intermediates in sucrose formation in plants[5,6]. Buchanan[7] has proposed that uridine diphosphate glucose and fructose-1-phosphate react to give sucrose phosphate, which is then converted to free sucrose. The results of the present experiments with peas are consistent with the hypothesis that uridine diphosphate glucose is involved (this substance may be formed from glucose-1-phosphate and uridine triphosphate[8] and the latter compound may be produced from uridine monophosphate through the operation of a glycolytic system); but it appears that free fructose (and not a phosphoric ester of this sugar) is an intermediate in the sucrose synthesis. This is in agreement with the results obtained with extracts from wheat germ[3].

I wish to express my indebtedness to Dr. L. W. Mapson, and to Prof. C. S. Hanes and Dr. F. A. Isherwood.

Financial assistance was provided initially by the Australian Commonwealth Scientific and Industrial Research Organization, and the work was continued during the tenure of a Broodbank Fellowship of the University of Cambridge. Support from these two sources is gratefully acknowledged.

A Model System for the Olfactory Membrane

IN the course of investigations on the kinetics of lysis of red blood cells by saponin and other hæmolytic agents, we have studied the effect of the addition of small amounts of various odorants. We describe below the unusual powers such adjuvants have in accelerating the process of hæmolysis. Somewhat remarkably, the activities of the odorants in this respect are paralleled by their activities in stimulating the olfactory cell membrane. This finding lends support to a theory of olfactory stimulation[1] which envisages 'puncturing' of the olfactory cell membrane by the odorant molecules.

Although little is known about the structure and composition of the olfactory cell membrane, there is reason to believe that it consists of orientated layers of cholesterol, phospholipids and proteins[2]. The layer may possibly only be bimolecular and yet remain impermeable to ions. In certain nerve cells it has been shown that there is an excess concentration of potassium ion inside, and an excess of sodium outside the cell. The cell membrane maintains its continuity by being partly liquid, some rigidity being provided, however, by cholesterol molecules and protein. The state of affairs is probably similar for the olfactory nerve cells. As a model, the red cell possesses the experimental advantage that, on penetration of the cell wall (and here again the lipids may form a bimolecular envelope[3]), the hæmoglobin is released.

It is found that, in the concentration-range studied, odorous substances act as weak hæmolysants. Thus a 0·005 *M* solution of skatol in isotonic buffered

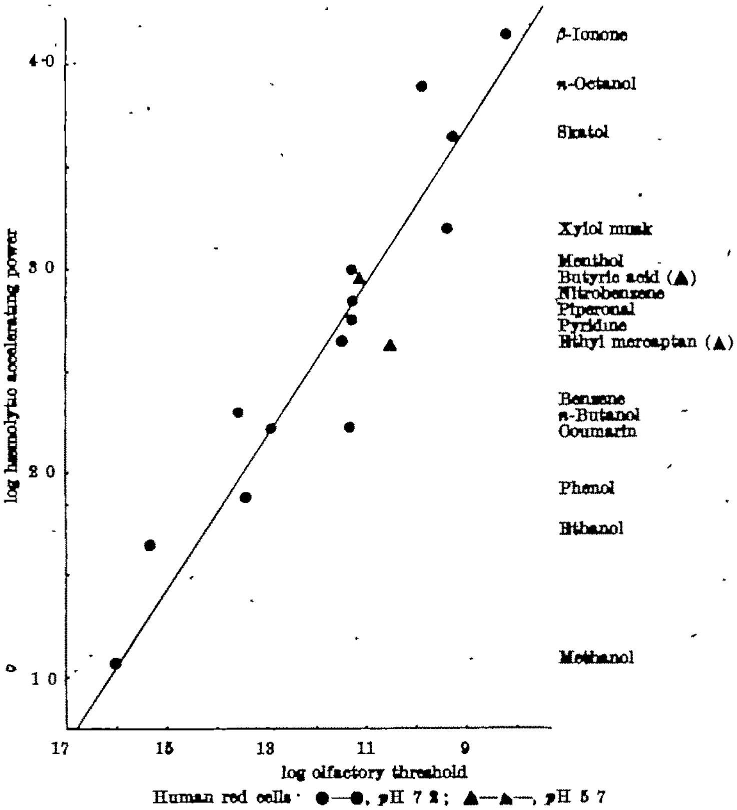

Fig. 1. Logarithm of the accelerating power of various odorants against the logarithm of the olfactory threshold. Values of the latter are recalculated from those given in the experimental literature. Experiments were carried out at 25° C.

saline at pH 7·2 and 35° C. took 60 min. to hæmolyse a dilute suspension of human red blood cells. Ponder[4] has reported that an indole solution containing 1 mM/l. completely hæmolyses a suspension of rabbit red cells in 30 min. at pH 6·3 and 25° C. A similar concentration of a strong hæmolysant such as saponin is effective in a few seconds.

We have found, however, that all the odorants tested acted as accelerators for hæmolysis by saponin. The exact mechanism by which these accelerators act is still under investigation; but the evidence indicates that the accelerant molecules interact with some component of the erythrocyte membrane, weakening it and facilitating the process of penetration by the saponin. This is in accordance with the findings of Ponder[4].

As a measure of the accelerating power of the odorant, the quantity

$$A = \frac{\left(\dfrac{1/T}{1/T_0} - 1\right)}{c}$$

was taken, where A is accelerating power, c is molar concentration of odorant, and T and T_0 are the times for the sample to undergo hæmolysis with and without odorant respectively.

The accelerating power is a measure of the extent to which the cell wall is weakened by the odorant. If the model is a good one, and if it is true that the odorant molecule is adsorbed on to and penetrates the olfactory cell wall, then we may expect a relation between the olfactory threshold and the accelerating power for hæmolysis. That this correlation does indeed exist is shown in Fig. 1, in which log A is plotted against the logarithm of the olfactory threshold (in molecules/c.c.). Substances such as β-ionone or skatol, which are powerful odorants (low olfactory thresholds), are also powerful accelerants; phenol and ethanol, having large olfactory thresholds (weakly odorant), are weak accelerators.

Little difference is found between the accelerating powers of *dl*- and *l*-menthol. Between n-butanol and perfluorobutanol, however, large differences are found; perfluorobutanol has a fairly powerful camphor-like odour; n-butanol is a comparatively weak odorant (O.T. = $8 \cdot 2 \times 10^{11}$ mol./c.c.) and is only half as effective as an accelerant.

At pH 7·2 the points for two compounds, both weak acids, lie well below the line; they appear less powerful accelerators than might be expected. This anomaly has been resolved by repeating these experiments at pH 5·7, when both additives exist entirely in the non-ionized form.

A series of isomeric methyl coumarins (kindly provided by Prof. Passerini) has also been investigated. It is found that 4-methyl coumarin, which is almost odourless, has less accelerating power than the other, and more strongly odorous, methyl coumarins.

Experiments with sodium decyl sulphate in place of saponin show that the odorants have similar accelerating effects on the hæmolysis.

We conclude that the structure and composition of the red cell membrane are such as to make it a good model for the surface of the olfactory cell. In view of the correlation shown in Fig. 1, and since hæmolytic acceleration is believed to entail penetration into the cell membrane with consequent weakening of the cell wall, we consider that our results lend support to the theory of olfaction which interprets the initiation of the olfactory stimulus in terms of such a process[1].

A full account of our findings will be published elsewhere.

Detection of Carbohydrase in Paper Electrophoresis

The task of testing and localizing enzymes in a protein mixture subjected to paper electrophoresis is a tedious one. This is particularly true in a fractionation study where the number of tests may be numerous. During the course of such an investigation of the various carbohydrases in an *Aspergillus niger* fermentation, it became necessary to employ a rapid qualitative test for the detection of these enzymes. Keilin and Hartree[1] have reported that glucose oxidase (notatin) can be successfully used for the quantitative assay of various carbohydrases. Monod and Torriani[2] employed notatin to determine glucose in their studies of amylomaltase. Recently, Whistler *et al.*[3] showed that D-glucose in corn syrups can also be quantitatively estimated by using notatin. The latter enzyme oxidizes glucose to yield two products—gluconic acid and hydrogen peroxide.

We were interested in detecting qualitatively two enzymes, maltase and invertase, and if possible limit dextrinase. The hydrolysis of maltose and sucrose (and possibly limit dextrin) liberates glucose. The latter is oxidized by notatin, and the resulting gluconic acid can be detected by spraying with an alcoholic solution of bromcresol purple or any suitable indicator dye. Control experiments showed that five gammas of gluconic acid or glucose could be easily detected on filter paper. The enzymatic activity of fifty gammas (equivalent to twenty gammas of protein) of crude material could be detected with ease. Appropriate blanks indicated that notatin in the presence of various substrates gave negative results.

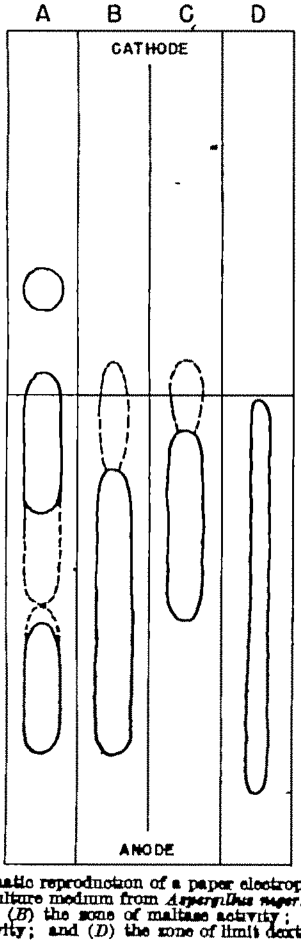

Fig. 1. Schematic reproduction of a paper electrophoresis experiment of the culture medium from *Aspergillus niger*. (*A*) The protein pattern; (*B*) the zone of maltase activity; (*C*) the zone of invertase activity; and (*D*) the zone of limit dextrinase activity

The method finally used was as follows. A freeze-dried preparation of the fermentation medium was subjected to filter-paper electrophoresis, as described by Kunkel and Tiselius[4], using a phosphate buffer, ionic strength 0·1 and *p*H 6·9. Four spots of the enzyme solution were applied to the middle of the paper (Whatman 3 *MM*) at 2·5-cm. intervals. After the completion of the run, the paper was cut longitudinally into four strips. One strip was stained with bromophenol blue[4] in order to ascertain the protein areas. While still damp (the strips were not allowed to dry out), the three remaining strips were sprayed with the following solutions: (1) a mixture of equal volumes of 2 per cent maltose and 0·5 notatin ('Dee O', obtained from Takamine Laboratory, Inc., Clifton, New Jersey, U.S.A.) for maltase activity, (2) a solution of equal portions of 2 per cent sucrose and 0·5 per cent notatin for invertase activity, and (3) for limit dextrinase activity a mixture containing 2 per cent limit dextrin and 0·5 per cent notatin was used. Each strip was covered with an eighth-inch wide mask while applying the above solutions in order to decrease excessive diffusion of the aqueous reagents. The strips were then clamped between two glass plates and incubated at 30° C. for half an hour, after which they were removed and dried at 110° C. Finally, the papers were sprayed with a solution of bromcresol purple (0·06 per cent in 95 per cent ethanol). The areas of enzymatic activity appeared as bright yellow spots on a bluish-grey background (Fig. 1).

This test should prove useful in detecting the presence of any carbohydrase which yields glucose as one of the end-products, and for this reason its application could be widely used.

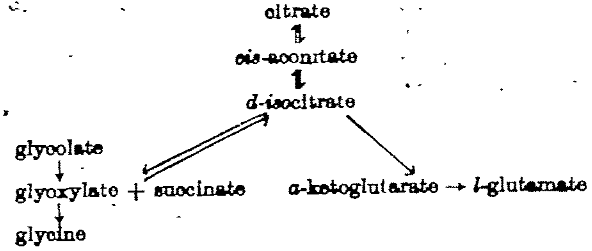
The *d-Iso*Citric Lyase System: the Formation of Glyoxylic and Succinic Acids from *d-Iso*Citric Acid

During studies on the acetate metabolism of *Penicillium chrysogenum* in this Department, it was found that alcoholic extracts of acetate-grown mycelium contained considerable quantities of glutamic acid and glycine, as well as a number of other metabolites[1].

In the course of this work, it was noted that citric acid disappeared rapidly on incubation with cell-free extracts of *P. chrysogenum* in the presence of arsenite, and that glutamate, α-ketoglutarate, glycine, glyoxylate and succinate formed. By varying the experimental conditions, it could be shown that citrate underwent cleavage along at least two pathways: (1) a complete breakdown to glutamate and α-ketoglutarate in fresh extracts fortified with magnesium chloride, arsenite, and a catalytic amount of TPN (not DPN); (2) a quantitative conversion to glyoxylate and succinate in aged (4 hr., 0° C.) or dialysed extracts in the presence of semicarbazide. If arsenite was used in place of semicarbazide, less glyoxylate accumulated and a large amount of glycine formed. Although the extracts were incubated aerobically, no oxygen was consumed.

The conversion of citrate to glyoxylate and succinate was found to be reversible. While the extracts to a limited extent were capable of oxidizing glycolate to glyoxylate, no citrate was formed in their presence from glycolate and malate. Furthermore, no detectable *d-iso*citric dehydrogenase activity was observed under conditions which were optimal for glyoxylate formation. On the basis of extensive inhibition experiments with α,α′-dipyridyl, trans-aconitate, ethylene diamine tetra-acetate, and potassium cyanide, it is considered probable that *d-iso*citrate is the immediate precursor of the cleavage products.

These reactions might be summarized as follows:



In the above scheme the direction of the arrows indicates the reactions identified, and does not necessarily relate to the reversibility of any individual reaction.

The enzyme system involved in the formation of glyoxylate and succinate from *d-iso*citric acid has been termed the *d-iso*citric lyase system. It has been found as well in extracts of baker's yeast, *Aspergillus niger* and *Rhizopus* sp. Further study on the characterization of the reaction system and on the isolation of its enzymic components is being carried out at the present time.

Glyoxylate has been known as a mould metabolite for many years[2], but the mechanism of its biosynthesis has remained obscure. The above-described reactions, demonstrating its facile formation from citrate by a cell-free enzyme extract of *P. chrysogenum*, indicate one possible pathway of its biosynthesis. In view of the fact that glyoxylic acid can be readily converted to glycine enzymatically[3], this reaction sequence may also account for the accumulation of glycine in the intact mould mycelium after incubation with acetate. The formation of glyoxylate from acetate has been suggested by Challenger[4], who found that glyoxylate and oxalate accumulated in the medium when *A. niger* was grown on calcium acetate. Whether or not glyoxylate has any function in the formation of oxalate remains to be seen.

Recently, while this work was in progress, Campbell[5] demonstrated the occurrence of an enzyme system in sonic extracts of *Pseudomonas aeruginosa* similar to that described above. This enzyme system converted citrate and *cis*-aconitate to glyoxylate and succinate, but *iso*citrate did not appear to be an intermediate.

Enzyme extracts were prepared at – 10° C. by means of Hughes' press[6] from frozen washed mycelium of *P. chrysogenum* Q176 grown in stirred aerated stainless steel fermenters[15] on an acetate salt medium and harvested in the late logarithmic phase. The crushed mycelial mass was centrifuged at 15,000 *g* for 20 minutes at + 2° C. The supernatant was frozen and stored at – 20° C., in which condition the enzyme system was stable for at least a month.

Glyoxylic acid was identified by the chromatographic behaviour, alkali instability, and characteristic spectrum of its 2 : 4-dinitrophenylhydrazone[7,8], and was crystallized from the reaction medium as its 2 : 4-dinitrophenylhydrazone, m.p. 189–192°, mixed m.p. 190–192°. Succinic acid was identified by its R_F values in several solvent systems and was estimated with a succinoxidase preparation[9]. Citrate was determined by the method of Taylor[10], *l*-glutamic acid with a carrot decarboxylase preparation[11], and total hydrazones by the general extraction procedure of Friedman and Haugen[12].

I am greatly indebted to Dr. D. Cavallini for a sample of the 2 : 4-dinitrophenylhydrazone of glyoxylic acid, and to Dr. C. B. Anfinsen for generous gifts of *cis*-aconitic anhydride and crystalline dimethyl *d-iso*citric lactone, observed m.p. 102–104°, reported m.p. 104–106° [13]. After mild alkaline hydrolysis of the lactone, the specific rotation of the molybdate complex of free *d-iso*citric acid was – 760° $[\alpha]_D =$ – 745° [14]. All other reagents were analytical grade commercial products.

A detailed account of these experiments is to be published elsewhere. I wish to express my sincere appreciation to Prof. E. B. Chain for his continued interest and helpful advice and for the hospitality of his laboratory, and to Prof. Domenico Marotta, director of the Istituto Superiore di Sanità, for his co-operation and support during the course of this work.

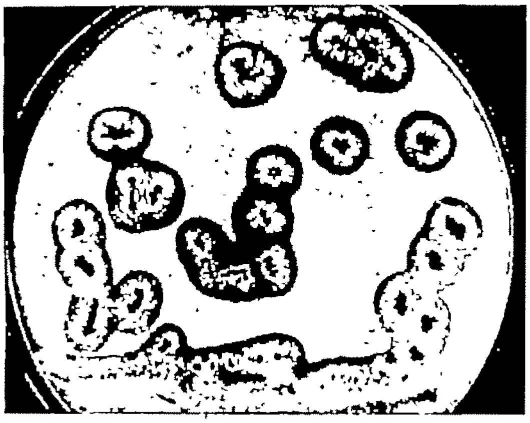
Decomposition of Oxalate by *Streptomyces*

THE microbial degradation of oxalate is relatively a rare phenomenon. During the last decade, however, some valuable information on the isolation and study of some more oxalate-decomposing organisms, mostly bacteria, has been reported. The work of Bhat and Barker[1], Janota[2], Muller[3], Khambata and Bhat[4,5] and Jayasuriya[6,7] has contributed substantially in this direction. Nevertheless, there seems to be no published data available on the decomposition of



Two-day culture of a *Streptomyces* sp. (isolated from cellulose enrichment medium) growing on oxalate agar. Decomposition of oxalate is indicated by the clearing of calcium oxalate (haloes) around the colonies. ½ nat. size

oxalate by *Streptomyces* and, so far as we are aware, this is the first report on this subject.

During the course of investigations on the micro-organisms associated with the intestine of the Indian earthworm[8], we encountered many *Streptomyces*. They were isolated from various enrichment media which were inoculated with suspensions of the intestinal contents of the worms. Details of the method of extracting the contents of the earthworm gut are obtainable elsewhere[4,5]. Three of these *Streptomyces* were isolated from oxalate enrichment media and exhibited oxalate-decomposing ability as evidenced by halo formation around the colonies when grown on a slightly modified Bhat and Barker's oxalate agar medium containing either yeast autolysate or yeast extract[4,6].

Stimulated by this interesting observation, we experimented further by streaking on oxalate agar twenty more *Streptomyces* isolated from the other enrichments also, namely, cellulose, asparagine and nitrogen-free enrichments. All, except one, displayed the characteristic clear-cut halo formation, strongly suggesting oxalate decomposition. The accompanying photograph strikingly illustrates the oxalate-decomposing ability of a *Streptomyces* species. Subsequent permanganate titrations carried out on eight-day old cultures of all the twenty-three *Streptomyces* grown in Bhat and Barker's liquid oxalate medium containing 0·1 per cent yeast extract confirmed our belief that oxalate was decomposed by these *Streptomyces*. Even the single isolate which did not exhibit halo formation on oxalate agar, on titration did show a negligible (0·2 per cent) decomposition of oxalate. The amount of oxalate decomposed by the other isolates varied from 6·3 per cent to as high as 83·4 per cent, but many decomposed more than 70 per cent of oxalate. It is, however, very necessary to emphasize the fact that our streptomycetes decomposed oxalate only in the presence of yeast extract. In oxalate media without yeast extract the *Streptomyces* gave scant or no growth. It may also be mentioned that three of these were identified as species closely related to *Streptomyces cellulosae*. The others could not be identified specifically but have been described in a doctoral dissertation submitted by one of us (S. R. K.)[8].

From these observations, it is felt that the oxalate-decomposing ability of *Streptomyces* is worth further exploration.

We are indebted to Mr. P. R. Gupta for taking the photograph.

Invasiveness of Sarcoma Cells

IT has recently been shown[1] that chick-heart fibroblasts in tissue culture influence each other's movement through their mutual contacts. In particular, it appears that when two fibroblasts touch, their further movement in the direction of their point of contact tends to be stopped. This phenomenon, which we called 'contact inhibition', is in principle capable of explaining many features of the behaviour of fibroblasts both in tissue culture and in the organism. Among other things, it implies a relative immobility within a group of fibroblasts, provided the group is enclosed by an external barrier of some sort, since the cells inhibit each other. Contact inhibition would therefore be expected to play a part in keeping the fibroblasts within an organism largely immobilized under normal conditions.

We have recently obtained evidence that contact inhibition occurs not only between fibroblasts from the same source, but between those coming from different organs and even from different species. A variety of cells are probably capable of immobilizing each other. The immobilization of cells within an organism breaks down, however, in the case of a malignant tumour. This suggests that sarcoma cells should be tested for contact inhibition against normal fibroblasts in tissue culture. The invasion of normal tissues by cancerous ones has previously been demonstrated to occur *in vitro*[2-4]. The observation that such invasion has occurred does not, however, necessarily mean that contact-inhibition has been absent. More direct tests are necessary.

We have made such tests, explanting two fragments of tissue close together in a liquid medium, and observing the two outgrowths of cells as they move towards each other on the solid surface and meet in the space between the explants. If contact inhibition operates between the cells of two such explants, there occurs a fundamental change of behaviour when junction between the two outgrowths is established: if they cannot turn aside, the cells almost stop moving. The result is that the space between the explants is filled by a continuous sheet of cells substantially one cell thick. This is what happens when the two explants are of neonatal mouse skeletal muscle, heart, bone or liver. When, however, one of the explants is from a mouse sarcoma (*S37* or Crocker, kindly supplied by the Chester Beatty Research Institute) and the other from one of these neonatal organs, the result is strikingly different. We have not been able to detect any change of behaviour in the sarcoma cells when they meet the fibroblasts. Both advancing outgrowths of cells continue moving after they have met, and become superimposed. We conclude that contact inhibition must be very slight or absent between these sarcoma cells and normal fibroblasts.

It would obviously be premature to assert that all malignant cells are characterized by reduction or absence of contact inhibition. A very large range of sarcomata and carcinomata, as well as of benign tumours and normal tissues, needs to be tested. Nevertheless, the hypothesis seems to be sufficiently plausible, in relating the invasiveness of malignant cells to a property of normal cells, to be perhaps worth following up by those who have access to a large range of tumours.

This work was made possible by a grant from the Nuffield Foundation, to which we wish to express our gratitude.

Intracellular Distribution of Histamine

ALTHOUGH histamine is widely distributed in the tissues, very little has been reported on its intracellular distribution. Recently, Copenhaver *et al.*[1] and Hagen[2], studying the histamine content of different cell fractions of dog liver, verified that the major amount of this substance was present in the mitochondrial fraction.

However, dog liver is exceptionally rich in mast cells[3], and the contamination of the mitochondrial fraction with mast cell granules during the differential centrifugation must be considered in the interpretation of these papers. We report here experiments performed in order to observe the distribution of mast cell granules in the different fractions of dog liver homogenate.

Samples of dog liver were obtained under pentobarbital anaesthesia and fractionated in 0·25 *M* sucrose as described by Schneider[4]. The nuclear, mitochondrial and microsome plus supernatant fractions were studied. Smears were made from these three fractions, fixed in 1 per cent lead sub-acetate in 50 per cent alcohol, stained with acidified Ehrlich's thionin and observed by normal and phase-contrast microscopy. Microscopic observation showed that the mitochondrial fraction was highly contaminated with mast cell granules which appeared as very small round metachromatic particles.

Many recent observations support the striking positive correlation between mast cell content of a tissue and its concentration of histamine[5]. Furthermore, the alterations of mast cells in conditions in which liberation of histamine occurs, both *in vivo* and *in vitro*[6], suggest that tissue histamine is present mainly in mast cells. By differential centrifugation of rat subcutaneous tissue a relatively pure fraction of mast cell granules could be obtained, and it was verified that the major amount of histamine was present in these granules, from which it could be released by heating in an acid medium or by the action of compound 48/80, a very potent histamine releaser. It is therefore probable that the higher histamine concentration of the mitochondrial fraction of dog liver might be due, at least in part, to its contamination with mast cell granules. A reconsideration of this problem seems to be necessary.

Destruction of Tumour Cells by Rift Valley Fever Virus

IN the course of work on the effects of infection with several viruses upon different kinds of tissue cells from several animal species *in vitro*, it was found unexpectedly that Rift Valley fever virus has a marked destructive action upon rat sarcoma cells grown in tissue culture. A number of papers have appeared on the effects of infection with viruses upon various tumours in several animal species[1]. A destructive effect of the viruses of eastern equine encephalomyelitis and poliomyelitis on the tumour cells grown in tissue culture has been demonstrated by Bang and Gey[2] and by Scherer, Syverton and Gey[3] respectively; but no report of an effect of infection with Rift Valley fever virus upon tumour cells either *in vivo* or *in vitro* came to our attention. It is felt, therefore, that the results so far obtained by us are sufficiently interesting to merit publication at this stage.

Rhodamine *B* rat sarcoma[4] and fructose mouse sarcoma[5] were used for tissue culture experiments. The roller tube technique was used and the cover-slip technique in Porter flasks was employed for staining cells grown in tissue culture. Suitable pieces of tumour tissues were grown directly on the glass wall of the roller tube without clot or upon the cover-slip in a Porter flask with or without plasma clot. Nutrient medium (1·0 ml. per tube) consisted of 45 per cent Hanks's solution, 45 per cent horse serum (or human ascitic fluid) and 10 per cent swine (or chick) embryo extract (1 : 1 in Hanks's solution). 100 μgm. of

† Mice inoculated subcutaneously with 0·1 ml. of the inoculum. Numerator = mice that died; denominator = mice inoculated.

streptomycin and 100 units of penicillin per ml. were added to the medium. Cultures were re-fed at intervals of three to five days. After the cells had grown for a few days, 0·1 ml. of a dilution of virus suspension was added, and the condition of the cultures was followed for more than ten days.

The virus of Rift Valley fever was obtained through the courtesy of Prof. T. Nagano, of the Institute for Infectious Diseases, Tokyo. The pantropic strain of the virus was originally isolated in East Africa by Daubney, Hudson and Garnham[6], and Endo[7] succeeded in producing the neurotropic strain by serial passages of the pantropic strain in Maitland tissue culture with embryonic mouse brain. The strain is essentially similar in its properties to that produced by previous investigators[8]. The strains of the virus were used in the form of suspensions of infected mouse liver and mouse brain respectively.

The results of one experiment with the pantropic strain of the virus are presented in Table 1. It was observed that the more concentrated viral inocula destroyed the rat sarcoma cells grown in tissue culture within two to three days, whereas cultures inoculated with higher dilutions of virus showed destruction only after four to six days (see Fig. 1). Considerable multiplication of the virus was confirmed by subcutaneous mouse titrations of the supernatant fluids of cultures inoculated with smaller viral inocula. The titre of virus in the culture fluids rose rapidly to a maximum of 10^{-6} to 10^{-7} in a few days before the appearance of marked cell degeneration.

Similar results were obtained with the neurotropic strain of the virus, and comparable results were also obtained in the tissue cultures of fructose mouse sarcoma with both strains of the virus. Destruction of these tumour cell cultures with both strains of the virus could be completely prevented by pretreatment of the virus with immune rabbit serum prepared against the pantropic strain of the virus. The destructive effect of the virus upon tumour cell cultures is comparable to that of the virus of eastern equine encephalomyelitis upon one culture of a malignant-cell line of rat cells (*T*-333) reported by Bang and Gey[9].

It may be noted here that both strains have also marked destructive effect upon normal tissue cells, namely, embryonic human, rat, mouse and swine fibroblasts. Since none of several neurotropic viruses so far tested for destructive effect upon the rat and mouse sarcoma cells grown in tissue culture showed an effect comparable to that of both strains of the Rift Valley fever virus, it seems probable that the marked cytopathogenic effect is an inherent property of this virus which is not dependent on its neurotropism.

The finding that Rift Valley fever virus multiplied readily in tumour cell cultures with destruction of tumour cells led to a preliminary study demonstrating a marked oncolytic action of the neurotropic strain of the virus, which is non-lethal for mice when inoculated either subcutaneously or intraperitoneally, on the Ehrlich ascites tumour. When the mixture of a dilution of the virus and the undiluted ascitic fluid, previously incubated at 37° C. for 1 hr., was injected subcutaneously into mice, the growth of subcutaneous tumour was completely inhibited, even when the higher dilutions of the virus were used.

In another experiment, 0·2 ml. of 1 : 10 dilution of the neurotropic virus ($LD_{50}\,10^{-7 \cdot 5}$) was inoculated intraperitoneally into mice, injected four days previously with 0·2 ml. of undiluted ascitic fluid.

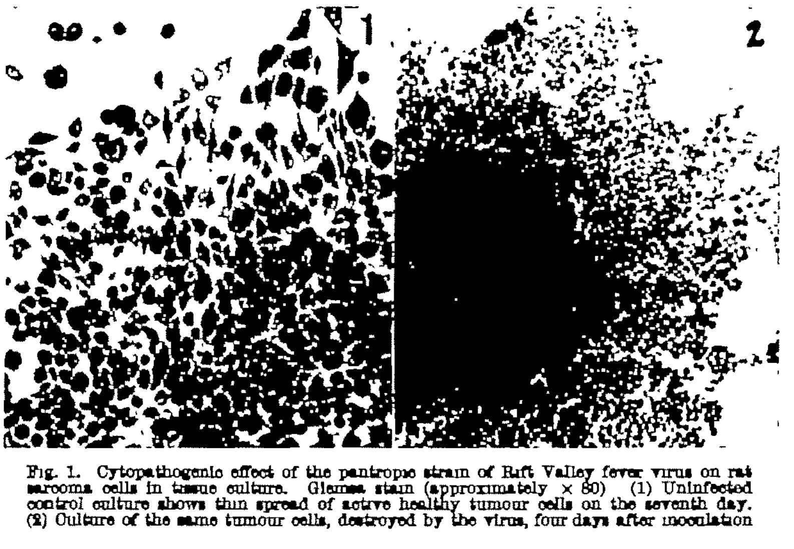

Fig. 1. Cytopathogenic effect of the pantropic strain of Rift Valley fever virus on rat sarcoma cells in tissue culture. Giemsa stain (approximately × 80). (1) Uninfected control culture shows thin spread of active healthy tumour cells on the seventh day. (2) Culture of the same tumour cells, destroyed by the virus, four days after inoculation

Marked destruction of tumour cells was observed, and in a few days no ascitic fluid could be obtained from mice infected with the virus. All the mice thus treated survived thirty days of observation, while the control ones died from ascites tumour. Mice receiving higher dilutions (10^{-2}, 10^{-3}, 10^{-4}) of the virus did not survive, although the amount of ascitic fluid was less than that of the control mice. The intracerebral mouse titrations of the supernatants of ascitic fluids showed that considerable multiplication of virus occurred. The oncolytic action was completely neutralized by pretreatment of the 1 : 10 dilution of the virus with immune serum. Koprowska and Koprowski[9] have already reported on a similar powerful inhibitory effect of Bunyamwera virus upon the Ehrlich ascites tumour.

Details of these and further experiments will appear elsewhere.

Glycogen Secretion in the Epididymis

Very little information is available on the function of the epididymis and especially of the nature of its secretion products. During a study of the histochemistry of this organ in domestic and laboratory animals pictures were obtained which indicated the presence of glycogen in the epididymal secretion products.

Small pieces from various parts of the epididymis were fixed in Carnoy's fluid or in Serra's[1] acetic acid–formol alcohol and embedded in paraffin according to routine methods. Sections were cut at 5 microns, attached dry to slides, deparaffinized in benzene, coated with a very thin film of 'Celloidine' and treated with periodic acid and Schiff's reagent. Control sections without 'Celloidine' coating were immersed in a buffered solution of malt diastase at 37° C. for one hour and then treated as above. Other controls were placed in the buffer solution only before the staining procedure. As chemical fixation often produces diffusion of glycogen with subsequent unreliable localization of the reaction product the freeze-drying technique was used in order to avoid this possible source of artefacts. The apparatus of Glick and Malmström[2] as modified by Moberger *et al.*[3] was used. Paraffin sections were cut at 5 microns, fixed dry to the slides, deparaffinized, dried in the air, and then immersed in a 0·2 per cent solution of 'Celloidine' in

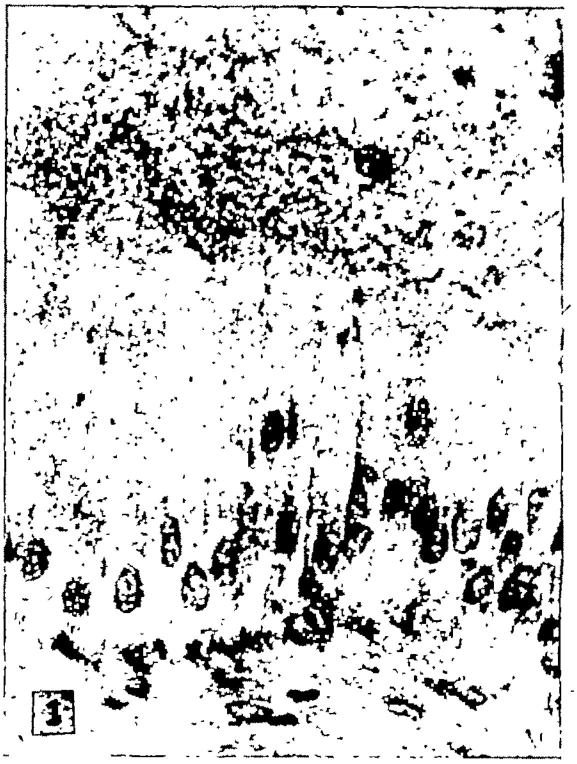

Fig. 1. Epithelium from the *corpus epididymidis* of rabbit. Large amounts of glycogen granules in the secretion. Fixation in Serra's fluid

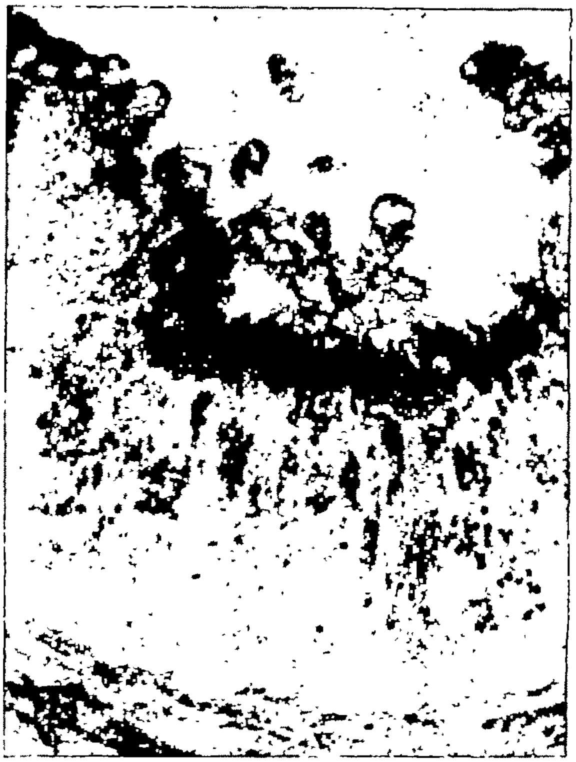

Fig. 2. Epithelium from the *cauda epididymidis* of dog. Moderate amounts of diffusely distributed glycogen in all secretion globules. The positive reaction in the stereocilia and intracellular granules is not due to glycogen. Frozen-dried specimen

ether and absolute alcohol. After drying in the air, the sections were treated with periodic acid and Schiff's reagent. Controls were prepared as described above.

Glycogen was demonstrated by both methods in the epididymal epithelium of several species, though in different amounts and different regions of the organ. In some regions moderate amounts were present in the secretion products. In globules lying free in the lumen, the glycogen was often less prominent or absent, especially in those intermingled with the spermatozoa. In frozen-dried material the reaction was diffusely distributed within the secretion globules, and stronger in their periphery. After chemical fixation small, heavily coloured granules were seen.

In the control sections a faint red colour persisted, and the stereocilia were generally still dark red.

McLeod[4] has shown that glycolysis and motility of human spermatozoa are produced by glycogen as well as by glucose and fructose under anaerobic conditions. The glycogen secretion reported here may therefore represent a mode of 'nutrition' of epididymal spermatozoa during the long time required for their passage through the organ.

A detailed description of the pictures observed in the different species will be published elsewhere.

Use of *p*-Chloromercuribenzoic Acid in the Determination of Ascorbic Acid in the Presence of Sulphydryl Compounds

In certain circumstances hydrogen sulphide, cysteine and related sulphydryl compounds react with 2 : 6-dichlorophenol-indophenol (indophenol) and thus may interfere with the determination of ascorbic acid using this reagent. In view of the known ability of *p*-chloromercuribenzoic acid to combine with sulphydryl compounds[1], the possibility of using this reagent to suppress such interference has been examined.

Results indicate that this reagent does not itself react with indophenol nor does it affect the determination of ascorbic acid in pure solution, using a colorimetric procedure based on the decolorization of excess indophenol. Under similar conditions the addition of *p*-chloromercuribenzoic acid has been found to suppress completely the decolorization of indophenol by hydrogen sulphide, cysteine and glutathione respectively.

The reagent has been used in the following manner: 1 ml. of *p*-chloromercuribenzoic acid solution (200 mgm./100 ml. in 0·05 *N* sodium hydroxide) was added to 3 ml. of standard ascorbic acid solution (0·0–2·0 mgm./100 ml.), or test solution, in 1·8 per cent (w/v) metaphosphoric acid solution. Because of the low solubility of *p*-chloromercuribenzoic acid at this *p*H (about 1·5) most of the excess reagent was precipitated. The solution containing the precipitate was allowed to stand for 5 min. and then centrifuged. To 2 ml. of the supernatant fluid was added 0·5 ml. sodium citrate solution followed by 1 ml. indophenol solution (4 mgm./100 ml.) and the optical density of the resulting colour determined 30 sec. after the addition of the dye using a Unicam spectrophotometer *S.P.* 600 at a wave-length of 520 mμ. The concentration of the sodium citrate used was such as to bring the final *p*H to 3·5. With solutions of ascorbic acid in 1·8 per cent (w/v) metaphosphoric acid a concentration of 7 per cent (w/v) was required.

It is suggested that *p*-chloromercuribenzoic acid may be of value in increasing the specificity of the indophenol reaction applied to the determination of ascorbic acid in biological material containing sulphydryl compounds. It offers advantages over mercuric acetate[2] for the removal of cysteine and certain other sulphydryl compounds in that subsequent treatment with hydrogen sulphide, to remove the excess mercuric ions and to convert the dehydroascorbic acid formed to ascorbic acid, is not required. It thus avoids a procedure which itself introduces several sources of error[3,4] and does not permit the determination of ascorbic acid in the presence of dehydroascorbic acid.

The effect of *p*-chloromercuribenzoic acid on the determination of the 'ascorbic acid' content of human plasma is being studied and it is hoped to publish results shortly.

We are indebted to Dr. A. B. Roy for the gift of the *p*-chloromercuribenzoic acid and for suggestions which led to its use described here.

A New Mixed Disulphide: Penicillamine–Cysteine

As part of a study of skin sensitization to penicillin and its derivatives, we have been investigating the behaviour of penicillamine (β,β′-dimethylcysteine). Since D-penicillamine proved capable of eliciting allergic skin responses[1], it was expected that it would react with epidermal proteins[2], possibly through cystine or cysteine residues. Accordingly, it was of interest to determine whether this sulphydryl compound reacts with cystine or cysteine. It was found that a reaction occurs readily with cystine with the formation of a mixed disulphide which is here designated penicillamine–cysteine.

A typical experiment consisted of mixing 1 mgm. of D-penicillamine and 2 mgm. of L-cystine in 0·4 ml. of 0·5 *M* ammonium chloride at *p*H 7·4. Aliquots were analysed by ascending chromatography on paper with phenol–water as solvent. A new ninhydrin-positive compound was found, $R_F = 0{\cdot}41$, about midway between cystine, $R_F = 0{\cdot}2$, and penicillamine, $R_F \simeq 0{\cdot}7$. The new compound gave a positive nitroprusside reaction only after reduction with alkaline cyanide solution. It yielded cysteic acid and penicillamine sulphonic acid after oxidation with aqueous bromine. Reduction of the compound with sodium sulphite solution at pH 7 yielded two distinct spots on paper: the more rapidly moving spot was indistinguishable from penicillamine and the slower ($R_F = 0 \cdot 1$) had the same R_F as material prepared by sulphite reduction of cystine[3]. Oxidation of these reduction products with bromine water yielded penicillamine sulphonic acid and cysteic acid respectively.

The mixed disulphide was prepared on a larger scale in the following way: 200 mgm. of D-penicillamine and 400 mgm. of L-cystine were mixed in 8 ml. of water which was adjusted to pH 9 with 5 *N* ammonium hydroxide. (Some of the D-penicillamine used was kindly furnished by Bristol Laboratories, Syracuse, N.Y., and by Charles Pfizer and Co., Brooklyn, N.Y.) The mixture was shaken intermittently at room temperature for eight days. The soluble fraction was evaporated to dryness, then dissolved in 2 ml. of 2 *N* hydrochloric acid and run on a 70 × 1·2 cm. 'Dowex 50' column in the hydrogen ion form (200–400 mesh, 8 per cent cross-linking). The chromatogram was developed with 2·5 *N* hydrochloric acid at a rate of flow of 5 ml. per hour. The fractions containing the mixed disulphide (430–545 ml.) were combined and evaporated to dryness *in vacuo* at 40°. The residue was dissolved in 1·5 ml. of 30 per cent ethanol–water (v/v). This solution was neutralized with 2 *N* ammonium hydroxide, and long, colourless, needle-like crystals formed immediately. After standing overnight at 4° the crystalline product was washed in the cold with water, 30 per cent ethanol–water and absolute ethanol. Yield: 50 mgm., m.p. 195° (dec.). Elemental analysis (Schwarzkopf Microanalytical Laboratory, Woodside 77, N.Y.). Calc. for $C_8H_{16}N_2S_2O_4$: C, 35·8; H, 6·00; N, 10·4; S, 23·9. Found: C, 35·8; H, 5·48; N, 10·1; S, 23·3. The compound is hygroscopic and the elemental analysis has been corrected for a water content of 8 per cent.

A rapid formation of the mixed disulphide of D-penicillamine and glutathione was also observed when penicillamine and oxidized glutathione reacted in *M* ammonium chloride solution at pH 7·4.

Studies on the reaction of penicillamine with various proteins are now in progress.

The support of this work by grants from the Standard Oil Company (New Jersey), New York City, and the National Microbiological Institute of the National Institutes of Health, United States Public Health Service, is gratefully acknowledged. A New Glass Cell for Preparative Counter-Current Distribution

We make a distinction between preparative and the usual counter-current distribution. By the latter we mean, of course, the very efficient method of separation based on extraction, devised chiefly by L. C. Craig[1]. With this method only a single addition of mixture to the apparatus is possible. This fact, although the amount added can sometimes be fairly large, limits the preparative value of the method. Several columns, working on a continuous basis (repeated or continuous addition of the mixture being possible) have been designed. These columns, however, lack the advantages of counter-current distribution where each cell is completely separated from the others. The principal advantages in this connexion are the easy mathematical interpretation and the possibility of stopping the operation at any time.

By preparative counter-current distribution we mean a technique based on separate cells and allowing repeated additions of the mixture to be separated. Such a technique has been described by Verzele[2]. The method differs essentially from the usual counter-current distribution in two ways: (*a*) the repeated additions must be made somewhere in the middle of the extraction train; this presents no difficulty; (*b*) the lower phase must be transferred also, and in a direction opposite to the displacement of the upper phase.

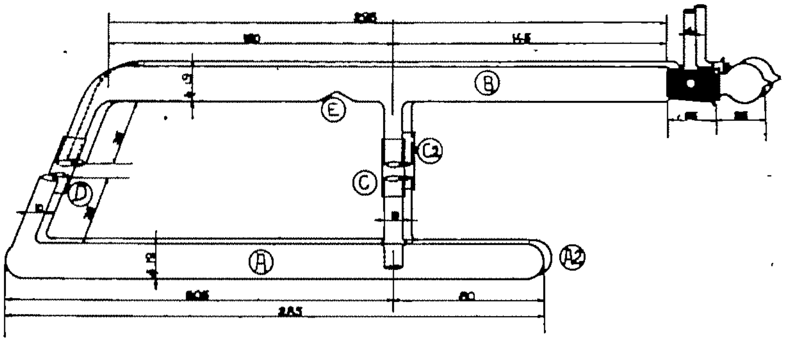

Fig 1

A new glass cell permitting the transfer of the lower phase is illustrated in Fig. 1. This new cell is a real improvement on the first model[2]. The lower half of the cell (*A*) is the agitation chamber. The stopcock permits easy removal of the solvents. *B* is the decantation chamber. *E* prevents the solvents flowing in the wrong direction. The cells can be joined together with plastic tubing or fused on to one another, depending on the ultimate use of the apparatus. Plastic tubing can sometimes be a nuisance when concentrations are determined spectrophotometrically.

Transfer of the upper phase. (1) Turn the cell 90° in a clockwise direction. The upper phase flows from *A* through *C* into the decantation chamber *B*. (2) Turn the cell farther in the clockwise direction to 200° from the original state. The lower phase of *A2*, withheld in *A2* by the extension of *C2*, flows through *D* into the decantation chamber *B*. The lower phase of *A* flows into the preceding decantation chamber, not shown on Fig. 1. (3) Turn farther clockwise to make a full turn (360° from the original position). The two phases flow together through *D* into the agitation chamber *A2*. Whereas the lower phase returns to the agitation chamber from which it came, the upper phase has been transferred from *A* to *A2*. Although the operation has been described stepwise, it is clear that a transfer of the upper phase is obtained by one uninterrupted full turn in the clockwise direction.

Transfer of the lower phase. Steps (1) and (2) of the upper-phase transfer remain unchanged. (3) The horizontal agitation state is attained by turning anti-clockwise for 200°. The two phases flow together through *C* into the agitation chamber *A*. The upper phase returns whence it came; the lower phase has been transferred into a direction opposite to the direction of transfer of the upper phase (from *A2* to *A*).

Transfer of the lower phase is obtained by turning 200° in a clockwise direction and back again.

It is obvious that the usual counter-current distribution can also be carried out with this cell.

A train of 216 such cells has been constructed in this laboratory.

Hydrogen Reduction of Tungsten Oxides

PREVIOUS work[1] has shown that hydrogen reduction of tungsten trioxide gave the β-oxide ($W_{20}O_{58}$)[2], which was then apparently reduced both to β-tungsten (*a* = 5·04 A.) and to tungsten dioxide or the γ-oxide.

Further work has been done on the reduction of the trioxide, dioxide and γ-oxide. The latter had the composition $W_{18}O_{48 \cdot 2}$, compared with the stoichiometric composition $W_{18}O_{49}$[3]. 25 mgm. and 50 mgm. samples and a hydrogen flow-rate of 600 c.c./min. were used instead of the 500 mgm. samples and 100 c.c./min. used previously. Reaction products were identified by X-ray diffraction analysis.

The first stage in the reduction of tungsten trioxide was always the formation of β-oxide. The final product was pure β-tungsten at 465°–584° C., but at 645° C. it consisted of α-tungsten and a small amount of the β-form. Samples partially reduced at 465°–645° C. contained only β-oxide and tungsten metal, but the dioxide also was formed at 677° C. and by reduction in moist hydrogen at 645° C.

The final products of reduction of γ-oxide at 470°–584° C. were α- and β-tungsten mixtures, the α-tungsten content increasing with increasing temperature. At 658° C. no β-tungsten was in the final product; but it was present in partially reduced samples. In two samples partially reduced at 470° C. and 540° C. β-tungsten was found unaccompanied by α-tungsten.

The sole product of reduction of the dioxide at 547°–587° C. was α-tungsten.

The following conclusions are reached from this and previous work. The primary product of reduction of tungsten trioxide is β-oxide. β-Oxide is reduced directly to β-tungsten, γ-oxide to both α- and β-tungsten, and the dioxide to α-tungsten. β-Tungsten is formed from the β- and γ-oxides even at temperatures where it is rapidly converted to α-tungsten. Formation of the γ-oxide and dioxide during reduction of tungsten trioxide is not, as was hitherto thought, a necessary stage in the reaction, but is due to insufficiently rapid removal of water vapour from the reaction zone. The γ-oxide and dioxide may be formed by oxidation of the β-tungsten, or by growth of γ-oxide and dioxide nuclei, formed by oxidation of the primary β-tungsten nuclei.

Only the dioxide was completely reduced to metal. The sigmoid time-course curves for the trioxide flattened out at compositions in the range $WO_{0 \cdot 2-0 \cdot 4}$ and at about $WO_{0 \cdot 08}$ for the γ-oxide. Thus, removal of the oxygen was not quite complete in those cases where β-tungsten was formed. This supports the suggestion of Hägg and Schönberg[4] that β-tungsten is a metallic oxide, with a maximum oxygen content corresponding to the composition W_3O.

I wish to thank Mr. M. G. Harwood, who was responsible for the X-ray crystallography, and Dr. J. A. M. van Moll and the Directors of Philips Electrical, Ltd., for permission to publish these results.

Quantitative Infra-Red Analysis of Mixtures

DIFFERENTIAL analysis of mixtures is an accepted technique in ultra-violet spectrophotometry[1], and it is the purpose of this communication to describe the successful application of this technique to infra-red solution analysis, where a double-beam instrument is used. Double-beam infra-red spectrophotometers enable complex mixtures of isomeric or closely related substances to be analysed; but it is usually necessary to detect a major peak peculiar to a particular component of the mixture. This is not always possible, and minor peaks, or peaks where interference is present, have been used. In the latter case corrections are applied for the interfering substance, which is separately estimated. Interference can also affect the shoulders adjacent to an analytical peak, so, while the actual peak is unaffected, the resultant extinction coefficient is questionable, because the true base line (I_0 value) is in doubt.

This interference was eliminated by adding to the compensating cell (usually containing solvent only) the interfering substance in a concentration equivalent to that present in the mixture, and dissolved in the solvent used in the sample cell. Alternatively, a different substance having an absorption peak at the same frequency may be used. The resulting trace shows the absorption of the mixture, less that of the interfering substance. Solvent absorption is eliminated by having low concentrations (which may involve thick cells) and using either matched cells or a variable-space cell of thickness similar to that of a fixed-thickness cell. This technique has been used for measuring the percentage of *trans* unsaturated fatty acids (expressed as elaidic acid) in the presence of *cis* unsaturated fatty acids and saturated fatty acids. Such an analysis is complicated by the fact that the *trans* double-bond peak at 965 *K** lies on the side of a major carboxyl peak at 933 *K*. It is therefore masked by this peak; but when a solution of mixed C_{18} fatty acids in carbon disulphide in the sample cell is measured against a similar concentration of stearic acid in carbon disulphide in a compensating cell of the same thickness, the carboxyl peak can be completely compensated and the resultant graph is that due to the *trans* double-bond alone. By this method 0·5 per cent *trans* unsaturated acids in the presence of *cis* unsaturated acids and saturated acids was accurately determined. Similarly, a mixture of DDT *pp′* and *op′* isomers and BHC γ-isomer was analysed by first compensating for total DDT at 1,015 *K* and measuring γ-isomer BHC at 686 *K* and 910 *K*, and secondly compensating for γ-isomer BHC at 910 *K* and measuring total DDT at 1,015 *K* and *pp′* to *op′* ratio at 806 *K*.

The method is also recommended as a criterion of purity. Similar weights of pure compound and sample are separately dissolved in equal volumes of an appropriate solvent and placed in matched sample cells. If the pure compound and sample are identical, the resultant trace is a line at 100 per cent transmittance and any impurity is readily detected.

Compensation by the above techniques may lead to low-energy transmission by each beam, and precautions may be needed to maintain instrument performance under the conditions of low energy and low signal-to-noise ratio. Such precautions include increasing energy from source, increasing slit widths, increasing electronic gain, and reducing consequent noise by the use of appropriate filters and slow scanning speeds.

A New Circuit for balancing the Characteristics of Pairs of Valves

In circuits containing balanced valves, as used in such applications as push-pull output stages or in d.c. amplifiers, it is customary to balance the valves by means of external circuit adjustments so that errors caused by differences in their characteristics are reduced. There are various methods of doing this[1]; but none of these gives compensation for all characteristics simultaneously, as it is possible to make adjustments to only one of the three properties, namely, zero balance (equality of static plate currents), stage gain and effect of changes of cathode-supply voltage.

Two valves of the same type rarely have identical characteristics, the variations being greater than can be accounted for by variations in electrode geometry. This is due to the well-known variations in the emission characteristics of the oxide cathode.

At a given operating point, differences in the characteristics of two valves caused by variation of the work function can be compensated by an appropriate adjustment of the cathode temperature and hence of the heater supply voltage.

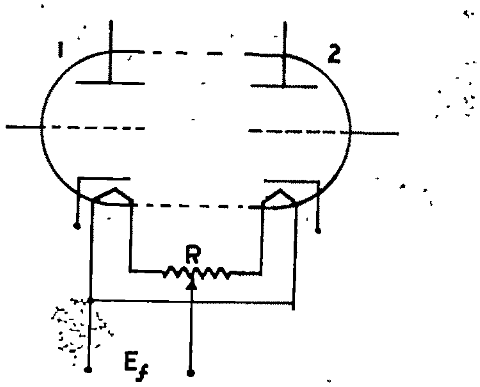

Fig. 1. A new circuit for balancing both static and dynamic properties of a pair of triodes by adjustment of the heater voltages

This approach leads to the very simple circuit of Fig. 1 for the balancing of a pair of triodes (or pentodes at fixed screen voltage). A small difference in the heater supply voltages is introduced by the potentiometer *R*, of a few ohms resistance, in series with the heater supply circuit. A suitable method of balancing is to adjust *R* until the static plate currents are equal. Experimental measurements on a number of valves of different types have shown that, when this is done, the other parameters of the valves are also brought into balance. That is, the mutual conductances of the two valves are almost equal (to within 2 per cent), and the compensation for heater supply voltage changes is also balanced. This result would presumably apply only to valves in which the differences in geometry are negligible.

It is found experimentally that it is necessary to provide for a difference of 10 per cent in the heater supply voltages, and that approximately 50 per cent of valves of the same type can be balanced with differences of only 5 per cent. In many cases (that is, d.c. amplifiers) it is desirable to operate the heaters at a reduced voltage, and the voltage drop in *R* is then unimportant.

Full experimental details will be published elsewhere.

Cytological Polymorphism in the Nematode *Haemonchus contortus* (Rudolphi 1803) Cobb 1898

Recent observations by Roberts, Turner and McKevett[1] have indicated that the so-called ovine and bovine 'strains' of *Haemonchus contortus* (Rud. 1803) are distinct species. This conclusion is based mainly on differences in the morphology of the infective larvæ and in the type of cuticular vulval process dominant in adult females in natural populations in each host. Supporting evidence was also found in heritability tests involving these differences. The measurements of the infective larvæ presented

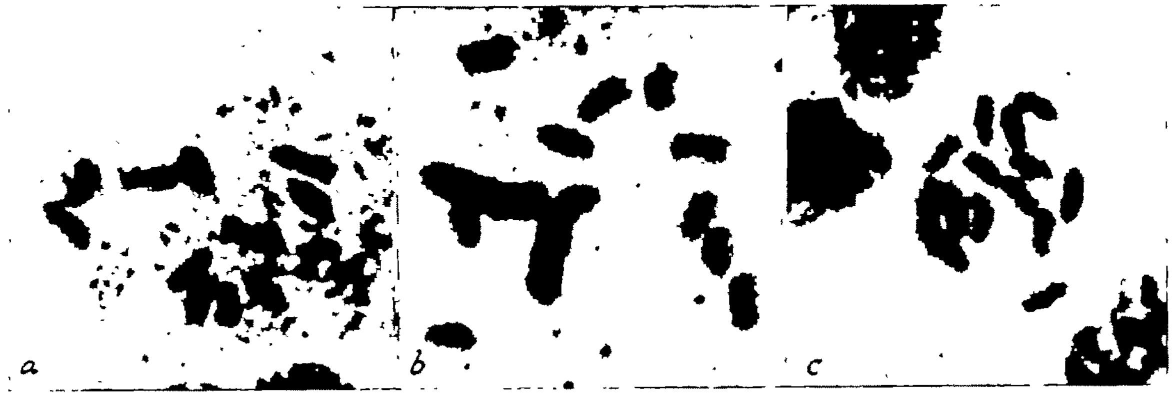

Fig. 1. Oogonial metaphase chromosomes of (a) *H. contortus* from a sheep; (b) *H. contortus* from a calf; (c) a hybrid *H. contortus*

by these authors, however, show some overlapping, and their heritability observations were carried only to the F_1 generation. For these reasons a cytological examination was undertaken and studies of the chromosomes were made on aceto-orcein squashes of the gonads.

In natural infestations the chromosome number for both forms is $2n = 11$ (♂), 12 (♀). Whereas gonial metaphase chromosomes of the worms from sheep are all of similar size (Fig. 1,*a*), those of the worms from cattle include one very large chromosome in the male and two in the female which are almost three times as long and twice as thick as any of the ten equal-sized autosomes (Fig. 1,*b*). These very large chromosomes are undoubtedly sex chromosomes, their increased size being due to the presence of heterochromatin, since they exhibit positive heteropycnosis along their complete length during prophase of gonial mitosis.

Examination of a pure infestation of cattle origin established in a worm-free calf showed the possession of large sex chromosomes to be a constant attribute of the form infesting cattle. It was also demonstrated that the presence of the large chromosomes does not influence in any way the type of vulval process in the female. A similar finding in respect of the chromosome picture was also obtained in naturally occurring infestations in sheep.

In an experiment designed to ascertain whether interbreeding occurs between the two forms, the large sex chromosomes were used as 'markers' and a worm-free sheep was given equal numbers of infective larvæ from cattle and from sheep. Infective larvæ from this lamb constituted the F_1 generation and were fed to a second worm-free lamb, which was slaughtered when the worms had reached maturity. Seventy-seven female worms from the second lamb were examined cytologically; of these, fifty possessed sheep-type chromosome complements, twenty-four the cattle type and three displayed a hybrid make-up, in which only one outsize chromosome was present (Fig. 1,*c*). The eggs from each of the seventy-seven females were cultured and those from all females, including the three hybrids, developed and hatched normally.

Another factor of interest was the finding of a triploid female among the parent generation in which the eighteen metaphase chromosomes were of equal length.

Although this experiment demonstrated the existence of a low percentage of a fertile hybrid form in an artificial population, it is highly significant that, to date, no hybrids have been found in examinations of natural populations.

Further work will be carried out on natural populations in which it is known that interbreeding has had every opportunity to occur over a number of years. The results of these observations will assist in deciding the question of specific distinctness.

Details of this work will be published elsewhere.

Photoperiodic Control of Germination in Seed of Birch (*Betula pubescens* Ehrh.)

It is well known that the flowering response of both short-day and long-day herbaceous species is governed by the day-length conditions to which the mature leaves are exposed, and that the meristematic tissue of the shoot apex is insensitive. It has been shown for certain woody species, however, that direct photoperiodic perception may occur in the meristematic tissue of both dormant resting-buds and actively growing apices, in relation to dormancy phenomena. Thus, the unchilled resting-buds of dormant leafless seedlings of *Fagus sylvatica* and *Betula pubescens*[1,2] may be induced to expand by exposure to long-day conditions. Similarly, actively growing, leafy seedlings of *Betula pubescens* may be induced to form resting-buds by direct exposure of the apical region of the shoot to short-day conditions, regardless of the conditions of day-length under which the mature leaves are maintained. It is of interest, therefore, to investigate whether the embryos of such woody species also show photoperiodic effects in relation to dormancy, and experiments have been carried out with seeds of birch for this purpose.

Preliminary tests showed that the *unstratified* (that is, unchilled) seeds will not germinate on moist filter paper in complete darkness at room temperature but will do so if exposed to light, and hence are light-requiring seeds. Experiments were carried out to determine the effect on germination of exposing the

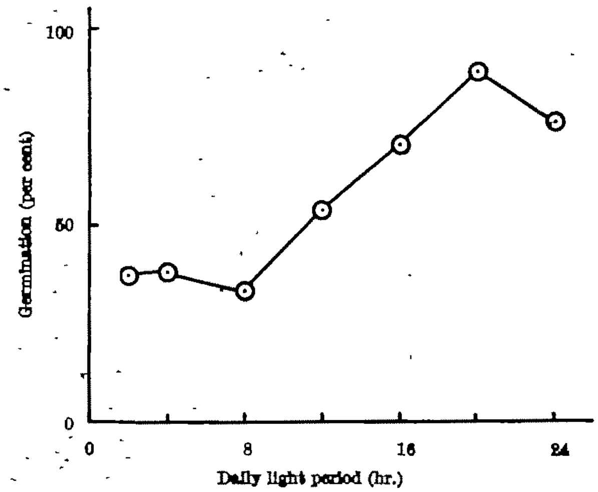

Fig. 1. Effect of day-length upon germination of unchilled birch seed. (Illumination with red light at 1,000 ergs/cm.²/sec. Temperature during both light and dark periods, 15° C.)

seeds to various lengths of photoperiod. For this purpose red light (falling within the range 5800–7000 A.) derived from red fluorescent tubes in conjunction with red 'Perspex' (*R*.400) was used, the intensity at the level of the seeds being approximately 1,000 ergs/cm.²/sec. It was found that the germination is markedly affected by the conditions of day-length, but that this photoperiodic response is profoundly modified by the prevailing temperature conditions.

Fig. 1 illustrates the effect of varying lengths of photoperiod, within 24-hr. cycles, at 15° C. The number of germinated seeds in each treatment was counted daily and the treatments continued until there was no further increase in germination, that is, for 12–14 days. (A considerable proportion of the seeds were found to lack embryos and these were excluded from the germination percentage.) It is seen that a high percentage germination is obtained with photoperiods of 16 hr. or longer, but under short-day conditions the maximum germination is only of the order of 30 per cent. A number of further experiments have been carried out which confirm that this is a true photoperiodic effect and that the final germination percentage is not governed by the total quantity of light received. For example, the percentage germination following exposure to seven cycles consisting of 8 hr. light/8 hr. dark was 60 per cent compared with 30 per cent following the same number of cycles consisting of 8 hr. light/16 hr. dark, although the total period of illumination (56 hr.) was the same for both treatments.

With higher temperature conditions (20°, 25° C.) the final germination was 93 per cent under both 8-hr. and 20-hr. photoperiods (with 24-hr. cycle) and the photoperiodic nature of the response is thus not apparent. At these higher temperatures even a single light-exposure followed by storage in the dark resulted in considerable germination (Table 1), whereas at 15° C., with corresponding periods c illumination, only a very low percentage germinatio was obtained.

Table 1. EFFECT OF SINGLE LIGHT-EXPOSURE ON PERCENTAGE GERMINATION AT 20° C.

Duration of light period (hr.)	0	0·25	1·0	4 0	8·0	20·0	24 0
Percentage germination	0	37·5	42·3	47·2	54·0	66·6	68 9

The effect of a single 4-hr. period of illuminatio with red light at 20° C. may be nullified if followe by illumination for 30 min. with infra-red radiatio (intensity 3,000 ergs/cm.²/sec.) within the rang 7200–10,000 A., and in this respect the responses c birch seeds resemble those of lettuce seeds[3].

Seed which had been soaked and stored in the dar at 5° C. for six weeks was found to germinate rapidl in darkness on transfer to a temperature of 15° C Chilled birch seed has apparently, therefore, no ligh requirement. There is thus a close parallel betwee the responses of both resting-buds and embryos o birch, for both structures show a requirement fo long photoperiods to overcome dormancy whe unchilled, but show no light-requirement afte chilling[2].

These effects in birch provide direct evidence i support of the hypothesis, put forward by Borthwick[4] and his co-workers, that the same photo-reactio is involved in both light-sensitive seeds and in photoperiodic effects observed in the later stages o development.

Magnetic Observations at Quetta during the Total Solar Eclipse of June 30

WITH the view of studying the effects of the total solar eclipse of June 30, 1954, on the magnetogram at Quetta, the Ruska magnetograph was set to run at 80 mm./hr., instead of the normal speed of 20 mm./hr. The Quetta Magnetic Observatory wa approximately three miles south of the northern ri of the shadow belt. The beginning of totality was 13h. 58·8m. G.M.T. and hence the corpuscular eclipse wa to be expected at approximately 11h. 59m. G.M.T.

The day was magnetically almost quiet. The horizontal force curve (*H*-trace) is entirely smooth a few hours before and after the eclipse period. At 12h. 1·6m. G.M.T. (2·6 min. after the expected corpuscula eclipse time), a full oscillation of a period of 1·3 min. and an amplitude of 0·8 γ appears in the *H*-trace. The onset is towards the positive side. The trac remained slightly disturbed until 12h. 47m. G.M.T. At the same time a slight increase of declination (*D*) by 0·1′ (1·0 γ) also occurred.

At 13h. 57·2 m. a very minute onset towards the positive side of *H* occurred. The amplitude of the onset is approximately 0·4 γ and consists of a sequence of irregular oscillations which last for 0·8 min. only.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. W. R. Bailey, F.R.S.: Presidential Address.

North East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre of the Literary and Philosophical Society, Newcastle upon Tyne), at 6.15 p.m.—Opening General Meeting.

Quaker Scientists' Fellowship (in the Small Meeting House, Friends House, Euston Road, London, N.W.1), at 6.30 p.m.—Sir Russell Brain: "Science and Religion".*

Friday, October 15—Saturday, October 16

Biochemical Society (at the National Institute of Medical Research, The Ridgeway, Mill Hill, London, N.W.7), at 2.30 p.m. on Friday and 11.30 a.m. on Saturday—Scientific Papers.

Saturday, October 16

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—The Reverend A. M. Jones: "African Music" (Illustrated by gramophone records).*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer, Grade B (with a degree and some teaching experience) in Biology—The Principal, North Staffordshire Technical College, Stoke-on-Trent (October 12).

Head (with experience of university scholarship work with sixth form) of the Geography Department—The Headmaster, Solihull School, Warwickshire (October 13)

Assistant Lecturer (professionally qualified and with adequate industrial experience) in Electrical Engineering—The Principal, Dudley and Staffordshire Technical College, Dudley (October 14).

Assistant Lecturer (with a degree in engineering and/or in agriculture, and practical experience of farm implements and machinery) in Agricultural Engineering—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (October 14).

Senior Scientific Officer (with a university degree of high standard in electrical engineering or physics, with mathematics or mathematical physics to final honours standard or equivalent qualifications) in the Aeronautical Research Laboratories, Department of Supply, Fishermen's Bend, Victoria, Australia, to be responsible for the investigation of instrumentation schemes in the field of aeronautical research, and detailed investigation of resultant problems and the subsequent development of necessary apparatus—The Senior Representative (A.P.22), Department of Supply, Australia House, Strand, London, W.C.2 (October 14).

Assistant Lecturer (Grade A) in Biology—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (October 16).

Laboratory Technician (with experience in general laboratory practice, the construction of experimental physical apparatus and instrument repair, and preferably with a knowledge of glass blowing)—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (October 16).

Principal (graduate in agriculture or appropriate sciences and with experience in teaching, practical farming and administration) of the Cumberland and Westmorland Farm School, Newton Rigg, near Penrith—The Director of Education, 5 Portland Square, Carlisle (October 16).

Research Assistants (2) at the Cavendish Laboratory to help with the work in radio astronomy—The Secretary of the Department of Physics, Cavendish Laboratory, Free School Lane, Cambridge (October 16).

Guide Lecturer (with a university honours degree, and experience in lecturing or teaching, and preferably with a knowledge of a foreign language) at the Victoria and Albert Museum, London—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting 4880/54 (October 19).

Assistant in the Department of Geography—The Secretary, The University, Edinburgh (October 20).

Soil Conservation Officers (graduates in agriculture or agricultural engineering) in the Federal Department of Conservation and Extension, Federation of Rhodesia and Nyasaland—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (October 20).

Assistant (with a degree in physics, together with some research experience and an actual or prospective interest in archæology) in the Archæological Research Laboratory—The Registrar, University Registry, Oxford (October 23)

Assistant Lecturer in Applied Mathematics—The Registrar, The University, Hull (October 24).

Lecturer in Agricultural Economics and Farm Management at the University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 25).

Senior Experimental Officer (with a pass degree in mechanical engineering or chemical engineering or H.N.C. in either of these subjects, and experience in the design, manufacture, development, installation and operation of process and chemical plant incorporating modern heat and mass transfer principles, or of heat exchange equipment used in power stations) in the Mechanical Engineering Research Laboratory, Department of Scientific and Industrial Research, East Kilbride, near Glasgow, for duties which involve the design (or selection) and development of heat transfer equipment—The Secretary, Civil Service Commission, 30 Old Burlington Street, London, W.1, quoting 84382/54 (October 26).

LIBRARIAN, Grade 3 (Fellow or Associate of the Library Association or with the Diploma of the London University School of Librarianship, and considerable experience (preferably technical) of library work, and preferably with a degree in a science subject, and a knowledge of languages) in the Ministry of Agriculture and Fisheries Veterinary Laboratory, Weybridge, Surrey—The Civil Service Commission, Burlington Gardens, London, W.1, quoting 4379/54 (October 28).

LIBRARIAN (with experience in a scientific library)—The General Secretary, The Chemical Society, Burlington House, Piccadilly, London, W.1 (October 29).

RESEARCH ASSISTANT (with some research experience in a branch of applied mathematics or numerical analysis, and preferably with previous experience of automatic computing) IN THE COMPUTING MACHINE LABORATORY—The Registrar, The University, Manchester 13 (October 30)

SENIOR LECTURER IN ANTHROPOLOGY at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, October 30).

CHAIR OF APPLIED MATHEMATICS at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Cape Town, October 31).

CHEMIST (graduate of a recognized university, and preferably with some postgraduate experience and training), with the Tobacco Research Board of Southern Rhodesia, for duties which cover the analyses of soils and tobacco leaf from experimental plots—The Director, Tobacco Research Board of Southern Rhodesia, P.O. Box 1909, Salisbury, Southern Rhodesia (October 31).

LECTURER IN VETERINARY SURGERY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 31).

SENIOR LECTURER and a LECTURER IN THE DEPARTMENT OF ZOOLOGY at the University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, October 31).

SENIOR EXPERIMENTAL OFFICER (with a pass degree in an appropriate subject, or technical qualification, and preferably with experience in research work and electronics, and prepared to undertake and supervise development of electronic apparatus) IN THE CENTRIFUGE UNIT of the Royal Air Force Institute of Aviation Medicine, Farnborough, Hants, to work in a small scientific unit concerned with effects of acceleration on man and animals—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S4383/54 (November 9).

LECTURER (Grade I) IN CHEMICAL ENGINEERING at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 15).

SENIOR LECTURER or LECTURER IN PHILOSOPHY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, November 15).

DEPARTMENTAL ASSISTANT (preferably with a degree in dairying) IN DAIRYING, at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

ENGINEERS and PHYSICISTS (Experimental Officer and Assistant Experimental Officer grades, with at least H.S.C. (pass degree, H.N.C. or near equivalent an advantage)), in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire areas, and in Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.247/52A.

RESEARCH ASSISTANT IN THE PHYSICS DEPARTMENT, for problems concerned with the design of a high pressure Wilson Cloud Chamber—The Registrar, Imperial College, London, S.W.7.

RESEARCH ASSISTANT (man or woman) in the field of physical chemistry (reaction kinetics)—The Secretary, University College, Exeter.

SCIENTIFIC OFFICER (with a first- or second-class honours degree in chemistry, and preferably with experience in thermochemistry, reaction kinetics and/or optical techniques), with the United Kingdom Atomic Energy Authority, Fort Halstead, Kent, for research on some of the physical and physico-chemical aspects of detonation and associated phenomena—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 225/WG/54.

REPORTS and other PUBLICATIONS

(*not included in the monthly Books Supplement*)

Great Britain and Ireland

The Oxford System of Decimal Classification for Forestry. (Being the definitive English version as authorized by the Rome Congress of the International Union of Forest Research Organizations, Sept. 1953, and published on their behalf by the Commonwealth Agricultural Bureaux.) Pp. 115. (Farnham Royal: Commonwealth Agricultural Bureaux, 1954.) 10s. [207

Department of Agriculture for Scotland. Memoirs of the Soil Survey of Great Britain–Scotland. The Soils of the Country Round Banff, Huntly and Turriff (Lower Banffshire and North-West Aberdeenshire). By Dr. R. Glentworth. (Sheets 86 and 96.) Pp. x+169+24 plates. (Edinburgh: H.M. Stationery Office, 1954.) 17s. 6d. net. [207

Department of Scientific and Industrial Research. Report of the Building Research Board, with the Report of the Director of Building Research for the year 1953. Pp. vi+66+16 plates. (London: H.M. Stationery Office, 1954.) 3s. 6d. net. [207

Brown's Coppice: a Survey. By the Natural History Society of King Edward VI Grammar School, Camp Hill, Birmingham. Pp. vi+79+11 plates. (Camp Hill, Birmingham: Natural History Society of King Edward VI Grammar School, 1954.) 5s. [207

MASS COMMUNICATION, POWER AND INFLUENCE

NOW that the Television Act is on the statute book and the chairman and director-general of the Independent Television Authority have been appointed, it should be possible to continue the public discussion of the real issues free from the heat engendered by the decision to make commercial television a party political matter. The composition of the governing body of the Independent Television Authority encourages confidence that every effort will be made to see that the development of television is fostered with due regard to the public interest, though it has yet to be seen whether in practice the high standards of public service established by the British Broadcasting Corporation can be maintained. Meanwhile, it should be apparent that the misgivings which are entertained on that score are due not to poor opinions of business interests or of advertisers, but rather to doubts whether the Authority possesses sufficient powers and independence to make the public interest prevail if a clash with commercial interests should arise. To insist that the public interest must prevail, or that the question of what is the public interest is not to be determined by those whose interests are immediately concerned, is no more to impute bad faith to such persons than to maintain that government departments should not be left to judge the public interest in matters in which they are immediately concerned is to impeach the integrity of the Civil Service.

It is only too easy to attack the motives of those whose belief that broadcasting and television represent instruments of immense power over the minds of men, the social and economic implications of which are not yet apparent, leads them to urge that both broadcasting and television should be treated in the same way and on the same plane as questions of education and other matters which profoundly affect the life and thought of whole communities. When the dust of party political conflict has subsided, attacks on the integrity of men like Lord Halifax and Lord Waverley, for example, can be seen for what they are worth; and the genuineness of the concern of such men that television and broadcasting may profoundly affect the character of our people for good or ill is unquestionable. It is indeed the belief that we need all the help we can get from this new instrument, of which science has made us masters, that has led to such stress being laid on the principle of public service—the principle that such power should be exercised responsibly for the public good. Broadcasting and television are necessarily and above all, as the Archbishop of Canterbury said in the debate on July 1, instruments of education. They provide ideas and information in such a way as to evoke, create, and contribute to mental, moral and spiritual reactions in the hearer or viewer. As with the cinema, their function as entertainment cannot be separated from this process of stimulus and reaction, even when it amounts to no more than passive acceptance. Indeed, the gravest danger of television appears to be that, instead of encouraging the process of education, it will foster a sluggish torpidity of mind which will render many incapable of being educated at all.

Even so, it would be going too far to consider the system created under the Television Act solely or even primarily as an educational instrument, though that aspect cannot be disregarded in considering any aspect of the system. What needs to be remembered is that this is a matter of influence, not of power, and its effect should be considered along with that of such other public influences as the Press and the cinema, and not in isolation. Failure to do so has encouraged the mistaken belief that the British Broadcasting Corporation possesses great power, whereas in fact it possesses little or no power but great influence.

Even the summary of the report of the Drogheda Committee* of inquiry into British Overseas Information Services, which the Government published last April, should help to remove that belief and to put broadcasting in its proper perspective as a vehicle for the communication of ideas and information. The Drogheda Committee could not avoid the conclusion that a modern government has to concern itself with public opinion abroad and be properly equipped to deal with it, and it followed accordingly that overseas information services play an important and indeed an essential part in support of foreign, Commonwealth and Colonial policies. The report faces fairly and squarely the implications of propaganda and counter-propaganda as a means of influencing public opinion in other countries, which the development of methods of mass communication has made possible.

It is obvious from the Government's treatment of the report, and the negative attitude which the Government spokesman, Mr. H. A. Nutting, had to reveal, particularly his denunciation of co-ordination, in the debate on July 6, that some, at any rate, of the findings of the Committee, and particularly its recommendations for a concerted and long-term policy, are unpalatable. But to the impartial observer, those findings, on the evidence published, are the more impressive because of the moderation with which they are presented. The case is not over-stated. Although the need for official information services is argued convincingly, it is never suggested that propaganda is a substitute for policy or for military strength, economic efficiency or financial stability. Its effect on the course of events is unlikely to be more than marginal; but in certain circumstances it could be a decisive factor in determining diplomatic success or failure. Even in this supplementary role, it can, however, make a contribution of outstanding importance to the efficiency with which Great Britain's resources are used to further policy.

The Drogheda Committee presents a case for the support of overseas information services, including broadcasting, with adequate resources for objectives which are broadly but clearly defined. No attempt has been made to refute that case, or to deny the Committee's assertion that the resources at present provided are entirely inadequate to meet those purposes. The increased expenditure of some two million pounds recommended by the Drogheda Committee, bringing the total to some twelve and a half million a year, is insignificant in comparison with its importance to the military and economic strength of Britain, and any political party which shirks finding the necessary funds because unpopular economies are involved elsewhere is clearly guilty of dereliction of public duty.

The published summary of this report shows how carefully the Drogheda Committee examined broadcasting as a means of influencing public opinion in relation to other means of promoting an understanding of the British way of life and point of view such as books, periodicals and newspapers. It is admitted that it is difficult to assess the effectiveness of any information service, whether spoken or printed, and that broadcasting as a means of influencing opinion is always in danger of falling between the two stools of the mass audience and the influential minority. Nevertheless, the Committee holds that the high reputation of the British Broadcasting Corporation External Service for objective and honest news-reporting is a priceless asset which sets that service apart from all other broadcasting systems. This high reputation for objectivity must be maintained at all costs, and the concern with which the Government's attitude to commercial broadcasting and television is regarded arises, at least to some extent, from the belief that the Government is unwilling to put at the disposal of the new Authority sufficient resources to make it independent of influences which could destroy that objectivity.

It is perhaps unlikely that any attempt will be made by the Government to use the British Broadcasting Corporation for anything in the way of direct propaganda; but, apart from indirect effects which commercial broadcasting might have, and also commercial television, measures which entail financial stringency threaten more than the scale of the Corporation's factual presentation to other countries of the news and of British views concerning the news. The Government must make up its mind either to provide sufficient support for overseas information services to enable them to be planned as a whole on a long-term basis, safeguarded against the changes which destroy efficiency, or see that the British Broadcasting Corporation itself is provided with sufficient resources to provide the services required without risk of their magnitude or content being subjected to sectional interests or pressure. Once the reputation for objectivity is lost or the opportunities for presenting the British point of view are missed they are not easily recovered.

These related problems are internal as well as external, and they were considered by Sir William Haley in the Clayton Memorial Lecture delivered before the Manchester Literary and Philosophical

---

* Overseas Information Services. Miscellaneous No. 12 (1954): Summary of the Report of the Independent Committee of Enquiry into the Overseas Information Services. Pp. 56. (Cmd. 9138.) (London: H.M. Stationery Office, 1954.) 1s. 9d. net.

Society last March*. That penetrating lecture, on the theme of the part which the Press and broadcasting play in building up public opinion and thus, in a democracy, in shaping public policy, deserves to be read widely. It is a valuable contribution to the clear thinking which is required on the problems arising out of the interplay of the means of information, education and entertainment in the world to-day and their bearing on wise government. The reception of the Drogheda Report itself is sufficient evidence of the dangers which arise if a government feels itself insufficiently secure to take steps imperative in the public interest because to do so may involve other unpopular measures the necessity for which could not perhaps be clearly explained to the public in the conditions of party political debate.

What Sir William Haley said bears closely on this vital matter of securing an alert, informed and intelligent public opinion. First, he explained the difference in the nature of broadcasting and the Press. Apart from its comparative novelty, though geographically the most pervading form of communication yet devised, broadcasting has limitations. Compared with the Press, it is comparatively inaccessible, being limited by time both in range and in space. Against the advantage of immediacy, especially on great occasions, has to be set its complexity and comparative inflexibility of operation compared with the Press. The Press, said Sir William, is far freer and less inhibited in political matters: because each individual reader can comprehend its output, a newspaper can have an impact which no broadcasting station can possess. It is not merely free to have a policy, an attitude, a way of thought: it can also make these things felt. Moreover, the printed word is more enduring than the spoken word, and while much of the best broadcasting is aimed at the emotions, most of the best journalism is aimed at the head.

Sir William Haley here makes a point which has received little attention in the debates over television and broadcasting of the past few years. The limitations to which he refers arise not out of the nature of the British Broadcasting Corporation and its monopoly; they apply to any system of broadcasting and are inherent in the nature of the medium. The use we make either of broadcasting or of television and the influence they exert in our own or any other community depend not only on technique and on the way in which we use them, but also on the nature of the medium. Ultimately, practical and physical considerations must determine what is done, and Sir William's comments on television in this connexion are shrewd and disturbing.

He emphasizes what is often overlooked—that over the programme field as a whole television, from its nature, cannot have the same range as sound broadcasting. Moreover, although television robs broadcasting of the great stimulus of the listener's imagination, for whole sections of the population television threatens to become the whole of broadcasting. Because thereby passivity instead of co-operation is encouraged, the whole educational purpose of broadcasting is at stake.

This is true whatever the outcome of the struggle between the idea of public purpose and commercial interest in television and broadcasting, and the picture Sir William gives of how much is at stake, particularly in politics and news, is disturbing. He pays a tribute to the way in which in the past the combined wisdom of Parliament, of the early committees on broadcasting, of the political party leaders and elder statesmen in both Houses of Parliament and of responsible directors and governors of the British Broadcasting Corporation, have given us a panoply of political broadcasting which has led the nation to be informed, persuaded, fairly exhorted, and given the requisite facts or opinions upon which to make up its mind, while simultaneously defending it against irresponsibility, demagogy and abuse. These same experienced forces, he believes, will bring wisdom and judgment to bear on the use of television, but they cannot ignore the nature of the medium with which they are working; and Sir William regards the coming of the television screen into every home, and the visual presentation of political affairs and politicians in this way, as a major sociological influence of our time.

Sir William Haley is disturbed because much news, particularly the most significant and important news, has no visual quality. The nature of the medium, accordingly, is likely to be continually at war with the real values of the news, and though he is confident that the B.B.C. will make an imaginative, courageous and thoroughly honest attempt to reconcile this conflict, he is less confident as to the outcome. On its outcome the future influence of both broadcasting and the Press may well depend; but it is difficult to feel as sure as Sir William that if the televized news bulletin proves a failure, the ordinary man or woman will revert to the printed word. There is the effect of television on the viewer, on education, and on literacy to be considered. Lord Reith was right at least in asserting that in the Television Act social, political, intellectual and ethical issues of incalculable gravity are at stake. He did not believe that its supporters would wittingly or willingly suborn moral responsibility or do moral hurt to their country at any one's dictation; but he may not have been so very wide of the mark in suggesting the possibility that the Government has surrendered a fundamental principle, moral values and intellectual and ethical objectives that should be cherished.

The reality of such dangers appears more clearly as we reflect upon Sir William Haley's observations on the inter-relations of the Press and broadcasting and the way their influence is exerted in the society of to-day. He believes that the Press still has great influence, but the character of its influence has changed; it is now not so much political as informative and interpretative, and while the great masses of the people may, as Sir William suggests, eschew opinions on the bewildering range of our manifold problems to-day and leave it to their representatives, we cannot entirely ignore the outlook and opinions of the general population. The serious Press is undoubtedly able to inform those representatives on hosts of important matters, and has sources of information and of informed judgment which in total are not available to the ordinary member of Parliament and can often supplement the knowledge of Ministers. Its influence on serious public opinion can be powerful, constructive, widespread and continuous.

---

* "The Public Influence of Broadcasting and the Press". By Sir William Haley. (Clayton Memorial Lecture.) (Manchester: Literary and Philosophical Society, 1954.)

Nevertheless, leaders of thought and action inside and outside Parliament, those of all classes in industry, the universities and schools, the professions, the churches and every walk of life who take an intelligent interest in events, still form only a fraction, though probably a greater part than formerly, of the nation. As voters in the electorate their influence could be ineffective, and Sir William Haley is clearly disturbed that the national temper may be such that the judgment and wisdom of the informed minority may fail to avert disaster. The symptoms and tendencies which he notes, moreover, may well be fostered as television encourages further both passivity and the expectancy that the individual can and should receive everything of the nation without contributing in return.

Sir William's own conclusion is not too pessimistic. He says quite frankly that certain daily and weekly newspapers with huge circulations among the less discerning and discriminating section of the community are indirectly and cumulatively building up an attitude of mind in the new generation which can be disastrous unless it is counteracted, and he points out that the Press has missed some opportunities which broadcasting has given it; but he recognizes that much of the Press has done and is doing fine work. He regards the Press and broadcasting as complementary, not inimical to each other. The Press, he suggests, could have concentrated on what broadcasting could not at one time do, namely, providing the background, explanation, opinion, exegesis and illustration, and maintaining a sense of values.

It does not appear, however, that Sir William is over-confident that should television take over the major part of the broadcasting audience and the televized news bulletins prove a failure, the popular Press will return to its proper role and again become an educative force. That might happen, he thinks, under the influence of public opinion, and he reminds us of the short time since we created a nation that can read. We have yet to make it a literate nation; whether television will assist or hinder that step remains to be seen.

Sir William suggested in this lecture that the most significant influence of the popular Press is now on what he calls morals, whereas the influence of British broadcasting has been mostly on manners. That influence could equally continue in television, but the arguments against commercial television indicate that widespread doubts are entertained as to whether in such a context television or broadcasting can raise standards of conduct or taste, or even maintain them. However that may be, Sir William's contention that the Press as well as broadcasting should resume their role as leaders rather than followers of public opinion is indeed timely Unless they remain true to their earliest ideals and seek to guide and uplift and not debase public opinion, we are on the way to an essentially uneducated nation, with all that is thereby implied in the abandonment of democracy and the growth of regimentation and intolerance.

What needs to be emphasized is that for the Press no less than for broadcasting and television, the educational purpose cannot, without danger to the whole basis of the British way of life, be subordinated to the entertainment function. The two purposes must be harmonized and reconciled, but it must not be by the abdication of leadership and the disregard of the responsibility for the accurate and fair presentation of facts, opinions and events. Sir William Haley denounces rightly as humbug and nonsense the doctrine that the public should be given nothing but what it wants, and that any design to give it or to lead it to want something better is highly dangerous and anti-democratic.

If, however, the Press and broadcasting are to exercise their role of leadership, they must recognize that their roles are complementary, and must respect each other's functions. Largely, broadcasting, perhaps even television, can be a stimulator, and the Press can satisfy the stimulated appetite. But how-effectively that educative function is discharged depends also on whether informed public opinion cares enough to maintain and advance standards, and to see that vigour and openmindedness are brought to the discussion of values and that no shibboleth goes unchallenged; and to speak out to that end, with vision, with care and with courage.

PRINCIPLES OF EXPERIMENTAL PHYSICS

The Physics of Experimental Method

By Dr. H. J. J. Braddick. Pp. xx+404. (London Chapman and Hall, Ltd., 1954.) 35s. net.

THE development of experimental ability rest not only upon example, precept and experience but also upon the prudent use of books which deal with the methods of experiment. Books of this kind with a wide range and suitable for advanced student are rather few. They tend to concentrate either upon laboratory arts and practice, or upon a course of typical experiments, or upon a range of particula instruments or measurements. Dr. H. J. J. Braddick' book has a different aim. Although he describe various techniques, experiments and instruments, h is concerned to bring out the physical principles by which apparatus may be designed and used to th best advantage in scientific experiments within th general field of physics. As Prof. P. M. S. Blacket remarks in the foreword, physical measurements ar now used in most sciences, so that the title "Th Physics of Experimental Method" has a topical appropriateness. No single book could fulfil so broad a title, and therefore the author has essentially t make an individual choice of the subjects included He treats, in fact, the general questions of th tatistical interpretation and mathematical manipu-ation of experimental results and also the natural imits of measurement set by thermal agitation and ther fluctuation phenomena. He describes four elds of measurement and methods, namely, elec-rical measurements and electronic devices, vacuum echniques, optical and photographic methods and a umber of the methods of nuclear physics. In these ields he gives in each section examples of the ppropriate instrument technology. He also makes ome observations on the construction of apparatus, oth design and materials.

The author writes little on the design of experiments, probably because it would have little relevance o the rest of the book. Similarly, he wisely limits he discussion of mechanical features to principles uch as kinematic design: mechanical engineering annot be compressed into a chapter. It was prob-bly also wise to omit subjects adequately treated in tandard text-books, such as bridges, potentiometers nd many electrical measurements. X-ray analysis nd electron diffraction and microscopy need special raining outside a general course. On the other hand, nterferometry, phase-contrast and polarization would eem to deserve places. Since d.c. amplification and ervo-systems are mentioned, the magnetic amplifier hould have been appropriately treated. The cathode-ay oscillograph has joined the more traditional tools f general application. Electrostatic instruments and igh voltages have now to be used by substantial groups of physicists. The most serious weaknesses are in the chapter on materials, where some data are quoted which are useful to industrialists for limited omparisons of similar materials by artificial tests, ut are quite misleading for any other purpose. The author would have done well to restrict himself here o physical principles as he has done elsewhere with uch success.

Criticisms of omission are but too easy; they do not mean that anyone else would have made a better hoice than Dr. Braddick. In general, he has made he wise selection which is to be expected from his nowledge, ability and experience. He has had to reserve a nice balance between subjects where a hysicist will need a special training, subjects where he physicist will usually give instructions to an nstrument technologist or laboratory technician, subjects where apparatus can be assembled as elivered from the makers, and subjects where the oung physicist, at least, will have to make some-hing himself. If Dr. Braddick has let the balance ome down somewhat on the side of his personal nterest, this is consistent with the spirit of original work. A book of this kind must be impressed with he character of its author. This character is that of a fine experimentalist and an excellent teacher. Some will think Dr. Braddick has attempted an impossible task; but a student's time is very limited, and he cannot learn everything that everyone would like him to know, so that usually a single book of this type must suffice for detailed study. Nevertheless, in the diversity of university education there is room for various outlooks. We might hope for other books to present outlooks different from that under consideration. Perhaps Dr. Braddick will write one or more of them. There is no doubt that he has made an important contribution to the literature of the subject, that his book should be made available to all advanced students of physics and that other scientists can be confidently recommended to consult it.

S. WHITEHEAD

A LANDMARK IN THE THEORY OF ELASTICITY

Singular Integral Equations

Boundary Problems of Function Theory and their Application to Mathematical Physics. By N. I. Muskhelishvili. (Second edition, Moscow, 1946.) Pp. viii+448. (Groningen: P. Noordhoff, N.V., 1953.) 28.50 florins.

Some Basic Problems of the Mathematical Theory of Elasticity

Fundamental Equations, Plane Theory of Elasticity, Torsion and Bending. By N. I. Muskhelishvili. Translated from the Russian by J. R. M. Radok. (Third, revised and augmented edition, Moscow, 1949.) Pp. xxxi+704. (Groningen: P. Noordhoff, N.V., 1953.) 38 florins.

THE first edition of Muskhelishvili's prize-winning monograph on the mathematical theory of elasticity was published in the U.S.S.R. in 1933. The second edition appeared in 1935, but was soon out of print; a third edition, considerably revised and augmented, was published in 1949. However, the extent of Muskhelishvili's signal contributions to the subject still remained comparatively unknown to Western scientists. The appearance of this translation, excellent in every way, is an event of first-rate importance.

It was in 1909 that G. V. Kolosov first demonstrated that a general plane state of stress in an elastic solid can be expressed, with profit, in terms of two arbitrary analytic functions of a complex variable. Muskhelishvili, first in a joint paper with Kolosov in 1915, and then on his own in a series of some twenty papers at intervals up to 1942, developed this idea in great detail and by its means solved a number of capital new problems and corrected or shortened the treatment of old ones. Kolosov and several other Russians, especially D. I. Sherman since 1934, have also contributed extensively. Similar ideas were formulated independently in 1939 in England by A. C. Stevenson, but the scope of the Russian work has been wider and much more thorough, and has drawn very considerably on complex function theory. In particular, Cauchy integrals play a prominent part, while the general solutions of the two fundamental and the mixed problems of elasticity have been obtained in the form of singular integral equations. Muskhelishvili and others have shown further that these general solutions are not only of academic interest, but also that they yield significant advantages over conventional methods in certain boundary-value problems.

The full account of the basic analysis is to be found in the book on "Singular Integral Equations". Its contents include chapters on the Hilbert and Riemann boundary problems, integral equations with Cauchy-type kernels, the Dirichlet problem, and solution of the generalized Riemann–Hilbert–Poincaré problem. A sufficient discussion of the relevant portions of this analysis appears in the book on elasticity.

The latter's range is indicated by the following selection from the twenty-five chapter headings: solution for regions bounded by a circle; application of conformal mapping; boundary values of holomorphic functions; solution of the fundamental problems for regions mapped on to a circle by rational functions; solution of the fundamental problems for the half-plane; some general methods of solutions of boundary-value problems; the problem of linear relationship. Complex variable methods are also used in the concluding chapters (amounting to about one-sixth of the whole), which treat the torsion and bending of simple and compound bars of different moduli.

Muskhelishvili's writings cannot fail to make the most vivid impression on every reader by their clarity, their pleasant leisurely style, and their scrupulous attention to detail. There is nothing slipshod in the entire thousand or so pages; every essential point is explained; the exposition is sustained on the highest level even through the appendixes (that on elementary tensor analysis has never been bettered, in the reviewer's opinion). If there is anything to regret, it is that the author's point of view throughout is that of a pure mathematician dealing with a branch of mechanics. The subject is not presented in the round: one aspect only is illuminated. But with what brilliance!

R. HILL

PROBLEMS OF WATER SUPPLY

Vegetation and Watershed Management

An Appraisal of Vegetation Management in Relation to Water Supply, Flood Control, and Soil Erosion. By E. A. Colman. (Sponsored by The Conservation Foundation.) Pp. xv+412+16 plates. (New York: The Ronald Press Company, 1953.) 7 dollars.

ALMOST everywhere in the world there is increasing domestic and industrial use of water, and the rising demand is making more and more difficult the task of the water engineer in supplying an adequate quantity of water of good quality all the year round. Leaving aside the doubtful possibility of significant weather modification by cloud seeding, the engineer's raw material is, at most, that part of natural rain and snow not lost to the atmosphere as evaporation from his catchment areas. This evaporation loss is predominantly a transpiration loss that gives an economic return where it is the working capital of the farmer and forester in the growing of crops, so much so that in many parts of the world it is deliberately increased—by irrigation—as a necessary condition for human survival. Removal of vegetation is not an acceptable solution of the water problem, even if clearance is restricted to that which is valueless as food or timber. The gain in total annual discharge would bring with it increased flood flow, more severe erosion on the catchment area and in the stream channels, more sediment in reservoirs, and still greater shortage of water in dry weather.

The role of vegetation in hydrology is obviously important, and there is complexity in the study of its many aspects: how it influences the evaporation loss, how it affects the retention of rain and snow on the ground, how it affects the penetration of rain and melt-water into the soil and so to underground storage, how it impedes run-off and restricts erosion. Given such basic information and some unifying ideas it should be possible to consider ways of managing the vegetation to exploit the good and minimize the evil effects. Much of the information does exist, and some of the ideas too; but the literature is very scattered, and there is a need for a comprehensive survey of present knowledge and practice. Dr. E. A. Colman, chief of a research division of the United States Forest Services, has attempted such a survey, but it falls a little short of what i could have been.

The book is written for the non-scientist; but this scarcely justifies Dr. Colman in discarding the precision of language he uses in his scientific papers to substitute a wordiness that leaves little or nothing to the imagination. The result is that interest flags as case after case is treated on its merits, based on the philosophy that results from one catchment cannot be applied to another in a different climate or with a different kind of vegetation. Scientifically, this is a philosophy of despair, but even if it is accepted as being all that is possible or desirable at present, the writing still suffers too much from needless repetition within sections. Drastic pruning would have made this a much better book, a book to be read with pleasure and profit.

The subject is so important that many British readers will be ready to take the profit and let the pleasure go, for this account of American experience in management of catchment areas covers a wide range of climates and vegetation types, including all that are found in Britain and many met in the Commonwealth. There are a long bibliography and two indexes—of authors and subjects—the second of which could usefully have been longer by adding more place names. Several of the famous management experiments, such as Wagon Wheel Gap and Coweeta, are best known by their sites; but sit names rarely appear in the index of subjects.

The book is well printed, with its subject-matte admirably illustrated in a collection of good photographs and some clear folded maps of the United States. The maps in black-and-white show th distribution of important hydrological elements another, in colour, shows the distribution of natural vegetation and the types of farming that have been imposed upon it. By modern standards the price is not exorbitantly high, and the book will prove a useful investment for those with an engineering or scientific interest in water, soil, or vegetation.

H. L. PENMAN

RELAXATION IN PHYSICS AND ENGINEERING

Relaxation Methods

By D. N. de G. Allen. Pp. ix+257. (London McGraw-Hill Publishing Company, Ltd., 1954. 53*s*. 6*d*.

An Introduction to Relaxation Methods

By F. S. Shaw. Pp. iv+396. (New York: Dove Publications, Inc., 1953.) 5.50 dollars.

THE method of relaxation has now become an established and important technique in mathematical physics and engineering. The object of the present two volumes is to provide a practical introduction to the technique of relaxation and to illustrate it by reference to the various types of problem which have been successfully solved by this means. As Mr D. N. de G. Allen so well emphasizes in his book, it i an essential feature of relaxation methods that they are extremely flexible and that they leave the maximum of initiative with the computor. For this reason there can scarcely be a completely systematic accoun of relaxation, since the whole spirit of the method is t avoid systematization. Both these books give a account of the various devices which have been successfully employed, such as over-relaxation, block relaxation, group relaxation and the use of multiplying factors; but the great purpose of each book is, of course, to stimulate the student to develop for himself the techniques which are appropriate to the special problems with which he is confronted.

The scope of these books covers linear algebraic equations, linear ordinary differential equations and certain linear partial differential equations, with a special emphasis on the questions of Laplace and Poisson and the biharmonic equation. Another important group of applications of relaxation methods is to eigenvalue problems for algebraic and differential equations. Quite another field of application is to problems where there are free boundaries the form of which is unknown at the beginning of the investigation. Allen's book also gives an account of the use of triangular nets, of the problem of heat conduction and of Southwell's method of intensification in calculating eigenvalues. Shaw's book also deals with the application of relaxation methods to integral equations, the use of Fox's "difference corrections" and gives tables for computing irregular star first and second derivatives near a boundary.

It is very difficult to compare two such similar works; but perhaps it is fair to say that Shaw's book is the more elementary and Allen's is the more philosophical. Certain omissions from Allen's book are quite deliberate, and the author promises another volume in which he will deal with a number of related topics. It would be extremely interesting to have a careful comparison of the method of relaxation with the method of squares as developed by Thom, Morris's escalator method and the hypercircle method of Synge. When a second edition of this book is called for, it would increase its value if some reference were made to the accuracy of the higher eigenvalues obtained by intensification methods and to Tosio Kato's method for estimating the accuracy of eigenvalues in general. G. TEMPLE

BELIEFS AND SOCIETY

African Worlds

Studies in the Cosmological Ideas and Social Values of African Peoples. Edited by Daryll Forde. Pp. xvii+244. (Published for the International African Institute.) (London: Oxford University Press, 1954.) 30s. net.

BY now a certain amount is known of the social life of non-Western peoples. In the African field we have analyses of political institutions and of kinship, and several general accounts of diverse social systems. This book is an attempt to discuss the beliefs associated with some of them, to analyse the character and the contexts of the value systems of certain African societies. We are given accounts of the cosmological ideas, myths and social values of nine peoples, of varying economic and political organization, from various parts of Africa, and an introduction by the editor.

For several years it has been one of the tenets of social anthropology that there may be a functional interrelationship between the parts of any social system. This hypothesis has been at least tacitly accepted, and research and analysis based upon it have shown its general validity. Research into religious and magical beliefs has demonstrated a close relationship between the system of social relations and that of values, sanctions, codes of conduct and so on, in any one society. An example is that of witchcraft beliefs. What may at first seem a jumble of superstition is integrated closely with, and derives its significance from, the social organization. It is also seen to form a coherent set of beliefs. Once certain premises are accepted—including some denied by Western scientific thought—then the entire structure built upon them is logical and reasonable. Such a system has two aspects, so far as analysis is concerned: its effectiveness in providing values and sanctions for orderly social interaction, and its coherence as a single set of beliefs. But although beliefs in witches may have a similar function in different societies, their form may vary. Similarly with, say, myths of the creation of the world, such as are described in this book. All these peoples have different ideas about the creation and the relationship of men with God and the world. One can regard these ideas as forming closed systems, quite apart from their place in the total scheme of social values. In other words, there is a distinction between the practical and the metaphysical significance of a set of beliefs. The distinction is implicit in every essay in this book.

A system of values, providing a guide to social behaviour, plays an integral part in any society. The types of organization of these various African societies vary, and with them the nature and significance of ties of kinship, territory and so on, from the great kingdoms of Ruanda and Ashanti to the stateless societies of the Lele and the Abaluyia. It can be expected that this variation will be reflected in the social values held by their members. If social anthropology is a comparative discipline, then here is an obvious case for taxonomy as a means towards understanding.

But it is not at all certain that this is so at the level of the myths and cosmologies also described. Since partly, at least, myths explain the place of men in the world, then the form of the society may be reflected to some extent in their content. Those of the Shilluk kingship provide an admirable example, as giving a means for the comprehension by the Shilluk, through the use of symbols, of the nature of the Shilluk polity. But there is much in Shilluk myth that seems to have no function, in this sense, at all. This is even more true of the cosmologies described, notably the elaborate system of the Dogon. Even here there is consistency, or at least a lack of contradiction. But this interrelationship is of a very different order from that between the form of social relations of a society and the code of behaviour prescribed by certain of its social values.

In short, this book tries to consider two problems, which are not clearly distinguished: the relationship between society and those of its values which guide social action, and that between society and its myths and cosmological ideas. There is clearly a functional relationship in the first case, but the nature of the relation in the latter is open to doubt. The myths may validate the existing status systems of persons and groups, but the cosmologies seem to defy attempts to analyse them as anything but closed systems of thought. We are given nine excellent and fascinating essays; but these do not, as one feels that perhaps they might have done, combine to make a book which advances our sociological understanding of religious belief. The fact that they do not do so raises the underlying problem of the ultimate limits of sociological analysis. JOHN MIDDLETON

ACOUSTICS OF THE SINGING VOICE

AT the Friday Evening Discourse given in the Royal Institution, London, on June 18, Mr. G. Mackworth-Young spoke on "What Happens in Singing". Much argument has been devoted to the question of whether singing is an art or a science. To the extent that the singer needs as his prime requisites a nice appreciation of pitch and good muscular control, it is primarily an art; yet in the process of learning to sing it is helpful to know something of the physics and physiology of the voice, though, of course, one does not while singing continually and consciously set the vocal apparatus into positions which theory would indicate as desirable. It is rather like riding a bicycle; at the beginning it is necessary to know something of the technique of propelling and balancing the machine, but in time this becomes automatic and to think consciously of each movement soon results in falling off.

The human vocal apparatus consists of the chest (bellows), larynx containing the vocal cords (source of vibration) and the throat, mouth and nasal cavities (resonators). The production of tone has often been likened to that in a reed pipe of the wood-wind class, but perhaps a brass instrument of the trombone type gives a closer analogy, since both the size of the resonators and the tension and length of the vibrating tissues are adjustable. The true or lower vocal cords are set in vibration by approximating their edges under the tension necessary to produce a note of the required frequency, and the breath is expelled through the narrow slit between them. This process sets the edges in vibration either as a whole (normal register) or in part (falsetto register), and these vibrations may be seen with a combination of the laryngoscope and stroboscope. The mathematical theory of this vibrating system has been given by Wegel. Experiments on excised larynxes have shown that, as would be expected, the quality of the unaided vocal cords is raucous and unmusical. It is mainly by the modulating influence of the resonating cavities upon the laryngeal tone that man is able to transcend the lower animals in speech and song, though the parrot and certain members of the ape family possess this faculty to a limited extent.

We turn to the important modifications produced on this still rather unmelodious 'buzzer' note by the resonance column, which it now has to pass through. The natural vibrations of the latter in the absence of a buzzer note may be heard in whispered speech or in whistling, when the vocal bands are drawn aside and a stream of air passes through practically uninterrupted at the larynx. Phoneticians usually distinguish three principal resonances: the back cavity (throat), the front cavity (of the mouth) and the nasal cavity. The acoustic impedance of the latter is then a 'shunt' upon the front part of the mouth. Further, the nasal cavity may be completely cut out, in the production of certain sounds, by the large impedance of the constriction where it joins the throat. In the absence of damping, each cavity may be regarded as an acoustic capacitance and each constriction as an inertance.

Of course, the division into capacitances and inertances must not be regarded as too rigorous. In some vowels the whole resonance system approximates to a wide open funnel stretching from larynx to lips. Actually, the damping is very large, much more so than in a wind instrument, owing to the resilient nature of the walls of the cavities. This has the practical effect of broadening all the resonances. It makes it rather difficult, in fact, to test the natural resonances of the system held in a given position by such methods as bringing tuning forks in front of the mouth. Again, although tables of resonances for various vowels are given, there are small discrepancies between the resonances detected by different investigators, and those not entirely due to phonetic uncertainties—for example, in the pronunciation of the vowels or the pitch of the cord note. Damping tends, in fact, to confound together the theories of Helmholtz and Hermann on the subject of the wave forms of vowels.

While it is true that we find, with the latter, that as one sings a vowel up the scale each cord-note has the 'formant' of the fixed resonance cavities impressed upon it, these resonances are so broad that the probability will be that a number of the harmonics of the cord-note will elicit some resonance in the mouth cavities, giving apparent agreement with the Helmholtz relative pitch theory of vowel overtones. This has the result that, within limits, the wave-form of a vowel is preserved as the cord-note is changed. This would not be so in a brass instrument where rigid walls and consequent sharp resonances impress a very pronounced formant on each note, altering the wave form as the player moves up the scale.

One difference between artificial wind instruments and the voice is in the type of resonance employed. In nearly all wind instruments standing waves are set up in the resonance tube, and the pitch of the note is therefore decided by the tube length. The voice, on the other hand, employs resonators of the Helmholtz type in which the inertance of the mouth and nose orifices is in series with the capacitance of the oral cavities. The resonance frequency therefore depends not only on the size of the cavities but also on the size and shape of the opening. The throat and mouth cavities are chambers of easily variable shape having soft elastic walls. They form resonators of low 'Q' in comparison to the resonator of a wind instrument, and so are readily tuned to a range of pitch. They accept a note from the vocal cords and give it body and quality by tuning their resonances to coincide with either the fundamental cord frequency or with certain harmonics. The auxiliary head resonators, being of fixed size and shape, contribute higher harmonics by forced vibration.

The fact that the bass voice can produce notes of wave-length 11–14 ft. indicates that here the voice resonance must all take place on the higher harmonics. Although the greater part of the sound energy is distributed among these harmonic resonances, we normally associate the pitch with the fundamental. This is due to the ear, which has the gift of extracting the fundamental, even if weak, from such harmonics as are presented to it.

Before dealing with the resonance compass of the various voices, it is necessary to consider briefly the question of vowel production. The combination of two resonances at a particular frequency produces an additional quality in the voice which no other instrument possesses and which the ear perceives as a vowel. Different vowels are produced by modulating the resonance of the cavities in much the same way as when reinforcing a vocal cord note. However, the vowel resonances ('formants') need not bear harmonic relation to each other. It follows that, in singing, the cavities are required to produce resonances which must be harmonics of the vocal note and at the same time fall within the formants of the vowel. These two requirements may conflict, and the claims of the note must then take precedence. This is the case in the upper range of the soprano voice where vowel production becomes a matter of great difficulty. The lower voices, being richer in harmonics within the resonant compass, are less troubled by this effect.

Much research has been carried out to determine the range of resonance in the throat and mouth cavities employed in the various voices, and recently this work has been greatly facilitated by the introduction of new electro-acoustic techniques. The normal range of resonance of the throat cavity for the male voice extends from $A_1\flat$ to $E_2\flat$ in the treble clef. Bass and baritone notes from the lowest up to $E_1\flat$ (on the bottom line of the treble clef) are reinforced on whatever harmonics lie within this compass. Notes lying between $E_1\flat$ and G_1 are resonated on the fundamental by a forced enlargement of the throat cavity. In women the normal compass of resonance stands squarely in the middle of the soprano voice extending upwards from the G_1 in the treble clef to the $F_2\sharp$ above. The notes within this range will naturally be reinforced on the fundamental, while lower tones find resonance on the first or second harmonic. When the voice rises above $F_2\sharp$ the throat resonance must be raised above its normal range, and this is achieved in trained voices by an enlargement of the throat cavity aperture.

Mr. Mackworth-Young has himself demonstrated the existence of two resonant zones in the throat having a compass of four semi-tones each in the men's voices (four and eight semi-tones in women's voices). It was found that if the vocal note happened to have harmonics in both zones, then both harmonics were heard. Notes which have two harmonics within the same zone may be resonated on either one but not both. The exact significance of this discovery awaits interpretation.

The normal compass of resonance for each voice shows a remarkable uniformity among singers of differing ages and nationality, individual variations rarely amounting to more than a semi-tone in either direction. The vowel, demanding as it does absolute pitch of resonance, is even more exacting in its requirements. This uniformity is achieved because the note of a Helmholtz resonator varies according to its size in relation to its opening; and as the mouth and throat capacities of the two sexes and various ages differ, so the mouth openings differ with them, thus maintaining the same proportions.

The throat cavity resonance on any particular note appears to be independent of the vowel which is being sung. It would appear, therefore, that throat resonance plays little or no part in vowel production, but the matter is still open to question. The nature of the vowel sounds has been under investigation since the beginning of the nineteenth century, and the pitches of the formants involved in the production of each vowel are now well established. For some vowels the lower formant does lie within the compass of throat resonance, while the upper formant is undoubtedly supplied by mouth resonance. For other vowels (for example, *ai* and *ee*) the mouth is divided by the tongue into two cavities which appear to provide the two formants independently of the throat resonance.

Much remains to be done to elucidate the acoustical processes in full of orchestral wind instruments; so it is with the voice. A good singer may be readily distinguishable from an indifferent one merely by listening to him; but if the indifferent singer is to be helped to improve, the scientific principles underlying the good singer's skill must be studied. In particular, studies should be made of 'attack' and 'vibrato' as practised by trained singers.

THE INTERNATIONAL BOTANICAL CONGRESS IN PARIS

IN 1854 the Société Botanique de France was founded, and it was very fitting that the centenary of this event should coincide with the meeting of the Eighth International Botanical Congress in Paris during July 2–14. The Congress was very well attended; the incomplete list of members and those accompanying members contains more than two thousand names, derived from about seventy different countries. Thus this Congress was even more truly international than that held in Stockholm in 1950.

The work of the Congress was divided between twenty-seven sections: International Union of Botanical Sciences; Nomenclature; Terminology; Taxonomy; Palæobotany; Palynology; Phytogeography; Morphology and Anatomy; Cytology; Genetics; Plant Physiology; Agronomy; Forestry; Standardization of Raw Materials of Plant Origin; Ethnobotany; Bryology; Phycology; Lichenology; Mycology; Plant Pathology; Bacteriology; Protection of Materials and Equipment; Soil and Water Microbiology; Nature Conservation; History of Botany; Botanic Gardens; Mediterranean Botany.

The above list may seem to disperse the subject over a very wide field, but it should also be noted that many sections were still further divided; for example, there were three sub-sections of Physiology, namely, Nutrition, Growth, Physiological Ecology. On a day chosen at random there were thirty-five different papers being read simultaneously; thus the subject had been so dissected that there were very few papers of general interest, and those attending the Congress had to be very ruthless in their decisions which section to attend, otherwise much valuable time was lost trying to keep track of two fields of interest housed in widely separate parts of the Sorbonne. One wonders if this process of sub-division has gone too far and there really is no longer a science called 'botany' but only some twenty or thirty separate sciences. One factor, however, eased this situation. The nine volumes comprising the Congress papers were available at the beginning and enabled one to decide which communications were most appropriate to one's own interest.

Most sections, while allowing time for miscellaneous communications, concentrated on a few main topics on which colloquia were held. These colloquia took the form of a *rapport* which usually summarized the position and lasted for an hour, followed by discussion for thirty minutes. Then came a series of brief communications by workers in the field under discussion. Thus one was given a fairly comprehensive background plus an indication of the growing points of the topic, and the discussion of the points raised was also very valuable. There were also many joint colloquia; for example, a discussion of "Quaternary Climate" organized by the Palynology Section was attended by the Phytogeography Section, while one on "Fungal Growth" embraced mycologists and physiologists.

The programme on the whole was well organized, although a lax attitude to time-keeping often meant that valuable communications were crowded out or had to be presented in a form so abbreviated as to be incomprehensible and almost valueless. There was also a certain confusion in some sections where papers were allocated 'time-units'. At an international congress, the symposium is the best form of meeting; but the clarity of the paper should not be sacrificed to length.

There was much variety between the sections in the use of language. The Congress programme laid it down that French and English were the preferred languages, but the writer also heard papers in German. One agrees that German should be allowed at such meetings; but in the discussions the use of an interpreter was urgently needed on several occasions, a question being asked in one language, answered in another, while part of the audience was more at home in a third. Translation, of course, uses valuable time but it is worth it, for those who do not understand may be those who might contribute most to the discussion.

It is impossible to give an adequate idea of the topics dealt with during the Congress, but there should be some indication of the subjects studied. Among others, the following were very valuable and interesting symposia: secondary and tertiary floras (palaeobotany); ecology of cold areas (phytogeography and ecology); experimental embryology (morphology); extra-nuclear inheritance (genetics); photosynthesis (physiology); photoperiodicity (physiology); morphological and physiological gradients (morphology and anatomy); forest pathology (forestry); ecology of marine algae (phycology); bryogeography (bryology); taxonomy of lichens (lichenology); fungal pigments (mycology); virus diseases (plant pathology); etc.

The social side of the Congress was well organized. The opening plenary meeting was held on July 2 in the Grand Amphitheatre of the Sorbonne under the presidency of the Rector of the University of Paris. Short addresses were given by Profs. Schopfer (Berne), Thimann (Harvard–Cambridge) and Heim (Paris). On the evening of Saturday, July 3, the Muséum National d'Histoire Naturelle gave a reception to all members of the Congress in the Zoo at Vincennes. Sunday was free to take advantage of the facilities offered by the Congress to visit the gardens and greenhouses of the Museum and the Arboretum Vilmorinianum in Verrières-le-Buisson. On Wednesday, July 7, at 5 p.m., the Congress met with the Société Botanique de France, and official delegates presented addresses and good wishes on behalf of their parent societies. M. Roger de Vilmorin delivered a short address and showed many beautiful coloured slides of the vegetation of France.

On Tuesday there was a general excursion to Versailles. The final general excursion was held on July 9, when many members enjoyed a day trip to Fontainebleau. The many members who attended had a relatively fine day which made botanizing in the Forest a pleasure.

There were sundry receptions for official delegates by various bodies; but the Congress concluded its official business at a plenary session on Monday, July 13. Here addresses of thanks and good wishes were delivered and the Congress closed with the decision that the Ninth International Botanical Congress should be held in Canada in 1958.

There were many excursions, some fairly local, some going as far afield as North Africa. In addition, the Section Mediterranean Botany held an extension of the Congress in Nice, where in addition to communications there were many excursions along the coast and into the mountainous hinterland.

In such a brief account of the proceedings of the Congress it is inevitable that emphasis is laid on those aspects of the proceedings which deserve re-examination. But criticism of details should not in any way detract from the general excellence of the work of the organizing committee. The Congress viewed *in toto* ran smoothly and well, and it is to be hoped that subsequent Congresses will follow the admirable precedents set by those at Stockholm and Paris.

A. R. GEMMELL

LOCALIZATION IN THE CEREBRAL CORTEX

A SYMPOSIUM on localization of function in the cerebral cortex was held in Oxford on September 8. Arranged by Section I (Physiology) of the British Association jointly with the Physiological Society, this symposium brought together workers from a number of disciplines converging on neurology and a large audience evidently drawn from many sections of the Association. Although the problem of cerebral localization is nowadays too complex to provide a clear-cut issue, there can be no doubt that it represents a convenient theme around which to group a variety of contemporary inquiries in the neurological field. The organizers of the symposium are to be congratulated on their choice of a topic which is not only of central importance in neurology but which also can be relied upon to attract widespread interest among biologists.

Intelligence and Brain-Size

The symposium was introduced—most appropriately—by Dr. E. D. Adrian, president this year of the British Association, who raised two important, if closely related, issues. First, the question of brain size in relation to the type of activity commonly called intelligent; and secondly, the mode of specialization of function within the cortex. As regards the first issue, Dr. Adrian pointed out that absolute size of brain no less than its general arrangement would appear an important factor in the evolution of the mammalian nervous system. He suggested that this might be explained either by supposing that an increase in brain-size permits greater subdivision—and hence localization—of function, or by assuming that intelligent activity depends upon a large amount of unspecialized cortical tissue. Both answers, in Dr. Adrian's view, are right up to a point, and the real question we have to ask is how much of the brain is allotted to special activities and "what happens to the rest".

Dr. Adrian then gave a summary review of the history of cerebral localization of function, ranging from Gall, through Broca, Fritsch and Hitzig, and Ferrier, to the more guarded concepts of localization characteristic of present-day neurology. While steering a careful course between the Scylla of extreme localization and the Charybdis of cerebral mass-action, Dr. Adrian left no doubt that the integration of behaviour to meet the needs of the environment presupposes, in his view, some measure of localization of its component functions. Only in the case of the sensory projection areas of the cortex, however, can we regard the evidence for functional segregation as really complete; and even here, Dr. Adrian was careful to point out, we cannot speak of the translation of sensory signals to sensation as being 'localized' in these areas—or indeed anywhere else. In the same way, he warned against the dangers of undue rigidity in arguing from the results of cortical stimulation experiments to the localization of motor function. In the control of behaviour, he suggested, total mass of cerebral tissue may be just as important as the finer details of structure. None the less, Dr. Adrian appeared to envisage some degree of cortical specialization, motor no less than sensory, the final integrative activity of the brain being unified in some way not as yet understood. "We are still entangled in the Departments," he concluded; "it may be long before we get through to H.Q."

The Excitable Motor Cortex

The problem of cerebral motor function was taken up in greater detail by Prof. E. G. T. Liddell (Oxford), who gave a masterly survey of experiments on the motor cortex, using the method of direct electrical stimulation. In discussing the earlier work, particularly that of Ferrier, he suggested that the punctate localization of discrete movements which it appeared to indicate was due at least as much to meticulous draughtsmanship as to the realities of cerebral organization. None the less, given the many and often ill-controlled variables in these experiments, the consistency of the results was not a little surprising. Turning to more recent work, Prof. Liddell directed attention to the great importance of proper control of the parameters of stimulation. He pointed out that the use of single strong stimuli in the anæsthetized brain, or of repetitive stimuli in the unanæsthetized human brain, leads to an appreciable increase in the size of the cortical area from which discrete movements of a given part of the body may be elicited. Had the earlier investigators used single instead of repetitive stimuli, he contended, they would have obtained a 'motor map' corresponding far more closely with that inferred by Hughlings Jackson from the sequence of events in epileptic seizures. He considered that the modern 'motor map', constructed on the basis of the responses given to single stimuli of varying intensity, provides an important clue to the functional organization of the motor cortex in man.

Prof. Liddell made it clear that the movements evoked by cortical stimulation can in no sense be equated with the 'voluntary' movements of the intact organism. Their time relations, in particular, are very different. Movements evoked by cortical stimulation show long latency and gradual build-up. Voluntary movements, on the other hand, are considerably more rapid. Evoked movements, moreover, are not unlike those obtained when the crossed extensor reflex of the cord is elicited by stimulation of a mixed nerve. This similarity, in Prof. Liddell's view, may be due to the fact that in both cases inhibitory no less than excitatory effects are involved. In support of this contention, he adduced the fact that weak single stimuli applied to the cortex evoke a 'flick' response of very brief duration.

Although these relationships stand in need of further elucidation, Prof. Liddell was able to offer a tentative hypothesis of cerebral motor organization. Integrated action, he suggested, presupposes inhibition no less than excitation. In voluntary movement, large groups of skeletal muscles must adopt a static postural attitude as background to the specific movement demanded. It is therefore likely that the central activity issuing in a particular movement, no matter how small, involves a large area, if not the whole, of the motor cortex. In this connexion, Prof. Liddell directed attention to the smaller cells in the motor cortex, which may well play an important part in integration, particularly in its inhibitory aspects. Although this hypothesis necessarily lacks precision, Prof. Liddell indicated its broad agreement with what is known regarding the organization of subcortical neural mechanisms, for example, the respiratory centre in the medulla, and with certain evidence from clinical neurology regarding the organization of the human motor cortex.

A Radical View of Cortical Motor Function

Dr. J. A. V. Bates (Neurological Research Unit, National Hospital, Queen Square, London, W.C.1) took issue with the traditional conception of the motor cortex as the 'repository of willed movements'. In Dr. Bates's view, the only inference that can be drawn from the results of experiments on cortical stimulation is that anatomical connexions exist between particular points in the cortex and particular groups of voluntary muscles. In this connexion, he referred to Burdon-Sanderson's demonstration (which he himself had confirmed) that precisely the same results are obtained by stimulation of the white fibres of the cortico-spinal pathway as by stimulation of the grey matter itself. Dr. Bates further stressed the infantile and athetoid character of the movements evoked by stimulation and their obvious similarity to epileptic phenomena. In his view, the only special qualities associated with cortical evocation are in relation to latency, facilitation and after-discharge. In short, the findings of cortical stimulation reveal no more than the facts of motor organization at the spinal level.

As further evidence in support of his thesis, Dr. Bates adduced the frequent contradiction between the results of experiments on stimulation and ablation of the motor cortex. In certain cases of long-standing unilateral brain disease, for example, he has found that a complete 'motor map' may be obtained from stimulation of the affected hemisphere. None the less, its removal is not followed by loss of the movements produced by stimulation. Despite the classical evidence of hemiplegia, therefore, it is becoming increasingly difficult to regard the motor cortex as in any sense the 'organ' of volitional movement.

In view of these, and many related, considerations, Dr. Bates has been led to propose the radical view that the whole conception of the cortical representation of movement, as evolved by Hughlings

Jackson and traditionally accepted in neurology, be abandoned. The only truly motor centres, he suggested, are in the spinal cord. "It may be that stimulation of the cortex in general does not demonstrate that fibres are efferent from a functioning motor centre, but rather that in the region of the electrode there is the origin of one of the many sets of afferents arising from perhaps a dozen or more different regions on both sides of the hind, middle and fore brains to impinge on each spinal centre." On this view, therefore, the cortico-spinal pathway is to be regarded as afferent rather than efferent in function, and the motor cortex itself as possessing no special role in the representation of voluntary movement.

It is plain that Dr. Bates's position implies a radical break with the traditional doctrine of the hierarchical organization of function in the central nervous system. Although his view is perhaps unduly extreme, it is unlikely that Dr. Bates meant to suggest that the cortex plays no part whatever in the initiation of voluntary movement—indeed, mere comparison of a decorticate preparation with an intact animal is sufficient to establish the contrary. What he doubtless meant to stress is that the motor cortex cannot be regarded as a 'centre for movement', that is, as an essential organ possessing its own intrinsic functions. Support for this view comes from many sources, not least the experiments of Lashley on the effects of ablation of the motor cortex upon acquired skills in rats and monkeys. None the less, it is unlikely that many neurologists will see fit wholly to endorse Dr. Bates's opinion at the present time. The more cautious view of Prof. Liddell, which ascribes some part at least of the integrative activity issuing in movement to the excitable motor cortex, is likely to secure a wider measure of acceptance.

Ablation Studies in Monkeys

The effects of ablation of small areas of the motor cortex in monkeys were described by Dr. F. P. Glees (Oxford), who directed particular attention to the summative influence of multiple small lesions in a given area. In the case of the 'arm area', for example, small lesions which individually occasion little or no disability 'sum up' in regard to their effects upon arm function. Dr. Glees further laid emphasis on functional factors in the establishment of connexions between the motor cortex and the effector organs of the body.

A short film illustrating tests of manipulative skill suitable for use with monkeys in ablation experiments was presented by Mr. J. Cole (Oxford).

Speech and Handedness

Prof. O. L. Zangwill (Cambridge) was concerned with the general relationship between handedness, cerebral dominance and aphasia. He directed attention to the frequency of aphasia associated with lesions of the left cerebral hemisphere in left-handed patients, and suggested that a dissociation between handedness and cerebral dominance is far from unusual. In explanation, Prof. Zangwill pointed to the fact that neither hand preference nor cerebral dominance is fully established at birth. In view of what is known regarding the growth of hand preferences in children, it is entirely possible that many left-handers owe their left-handedness not to heredity but to some more or less contingent circumstance of early development. In such cases, he argued, it would appear that language none the less becomes organized in the left hemisphere, as in the congenitally right-handed individual. At the same time, Prof. Zangwill was careful to indicate the complexity of the relationship between innate and acquired factors in cerebral dominance and the need for their further elucidation.

Cortical Factors in Nystagmus

Dr. E. A. Carmichael, Dr. R. M. Dix and Dr. C. S. Hallpike (National Hospital, Queen Square, London, W.C.1) reported on the effects of localized cerebral lesions upon optokinetic and caloric nystagmus. Dr. Hallpike, who read this paper, pointed out that a characteristic disturbance of optokinetic nystagmus, presented as directional preponderance towards the side of the lesion, occurs only when the latter involves the posterior parietal region of the cortex. A comparable disturbance of caloric nystagmus, on the other hand, occurs only in cases in which the posterior temporal region is involved. Although both types of nystagmus are known to depend on subcortical reflex mechanisms, Dr. Hallpike pointed out that the cortex must obviously exert a modifying influence. Its precise nature, unfortunately, is not at present understood. None the less, these findings have evident value in providing additional 'localizing signs' of circumscribed cerebral disease.

O. L. ZANGWILL

HORMONES AND CONTROL OF ZOOLOGICAL FUNCTION

A MEETING of Section D (Zoology) of the British Association was held in Oxford on September 7, with Prof. J. E. Smith in the chair, to discuss "Hormones and Control of Zoological Function". It was opened by Mr. D. B. Carlisle with a review of recent advances in our knowledge of the hormonal control of moulting in the Crustacea. The discovery during the past few years of the true nature of the X-organ – sinus gland complex of the eye-stalk has proved a stimulus to research in this field, and it is now established that the accelerating effect upon moulting of removal of the eye-stalk in crabs and crayfish is a result of the production in the neurosecretory cells of the X-organ of a hormone which is stored in the sinus gland and which restrains the onset of the moult. Carlisle brought forward evidence that the contradictory results sometimes reported may be due to the existence in most higher Crustacea (except crabs and crayfish) of a second (distal) part of the X-organ which resembles the sinus gland in consisting partly of enlarged nerve endings. In such forms the neurosecretory complex of the eye-stalk produces a second hormone which accelerates the processes of the premoult, probably acting primarily upon the separation of the old shell; and the effect of the removal of the eye-stalk will then depend upon the balance normally existing between the two hormones. This, he suggested, could account for the fact that in some species the operation had been found to result in either acceleration or retardation of the moult according to the particular population under investigation.

Moulting itself cannot be regarded as an isolated act, for it is preceded and followed by periods in which the metabolism and behaviour of the animal are greatly modified, while growth, in the sense of increase in organic matter, takes place during the intermoult phase when the metabolism and behaviour have returned to 'normal'. Since the moulting hormones influence the duration of this latter phase, they must be regarded also as growth hormones, and it is to be expected, therefore, that further complications of endocrine control remain to be revealed in this field; it is thus significant that Gabe has recently postulated a third hormone, in the absence of which the act of moulting cannot take place even though the premoult may have proceeded normally.

Elasmobranch Endocrine Organs

Research in vertebrate endocrinology has been concentrated so largely upon the Mammalia that there exist at the present time startling gaps in our knowledge of the lower forms, a situation well brought out by Mr. C. K. Goddard's review of the physiological status of elasmobranch endocrine organs, in which he referred also to work in progress at the Gatty Marine Laboratory. The pituitary appears to be the 'master gland' in this group, as in others; but the evidence for the existence of some of its expected hormones is very incomplete, and there is need for much more information as to the source of these hormones within the gland. So far, only the chromatophore-expanding and diabetogenic hormones have been localized, the former in the neuro-intermediate and the latter in the anterior lobe. Thyrotrophic hormone is thought to be present, but the evidence for its existence is meagre in the extreme; indeed, evidence that the thyroid shows little or no sign of involution at nine to ten weeks after hypophysectomy, and that goitrogens are ineffective, as judged by histological criteria, at dosage-levels that will elicit a response in teleosts and mammals, would seem to cast some doubt on the importance of this hormone in elasmobranch physiology.

Gonadotrophins are thought to be present in elasmobranchs, for hypophysectomy results in a slow involution of the gonads; it has also been claimed that the pituitary is necessary for ovulation in the viviparous *Mustelus canis*, but this appears not to be the case in the oviparous *Scylliorhinus canicula*. Possible endocrine functions of the gonads are suggested by observations that testosterone will increase the length of the claspers in young males and that oestrogens cause growth of the reproductive tract in young females; but this is a field in which direct evidence is greatly needed. Work so far done on the inter-renals has provided evidence that they are essential to the life of the skate, and that extracts prepared from them will maintain life and growth in adrenalectomized rats, while mammalian cortical extract has been found to prolong the life of inter-renalectomized *Torpedo*. Such observations support the view that the elasmobranch inter-renals are the homologue of the mammalian adrenal cortex; but the fact that they seem to play no part in electrolyte metabolism suggests at least one important difference in function. It seems clear that the comparatively few pioneer workers in elasmobranch endocrinology have inevitably been much influenced by preconceptions drawn from mammalian physiology. The results so far obtained certainly suggest some similarity of pattern between the lower and higher vertebrates, but the evidence at present is so fragmentary that it would seem prudent at this stage not to anticipate too close a correspondence, but rather to be vigilant for the significant points of difference.

Use of the South African Clawed Toad

One of the obstacles to the study of elasmobranchs is the obvious difficulty of maintaining them satisfactorily in the laboratory, and a refreshing contrast to this is evidently provided by the South African clawed toad, *Xenopus laevis*, which was dealt with in the next two papers, and which was shown in them to be an admirable subject for endocrmological research and assay. This animal, which can be induced to reproduce at any time of the year, and which differs from British amphibians in lacking the complication of a terrestrial phase in its life-cycle, has proved of value in pregnancy diagnosis; analysis of the influence upon it of gonadotrophins is thus of considerable practical importance, and was the subject of Mr. B. M. Hobson's review. The effect of the pituitary in maintaining the activity of the gonads is clearly shown by the results of hypophysectomy, which leads in six months to a 70 per cent reduction in the weight of the ovaries and a 66 per cent reduction in that of the testes, while marked regression of the oviducts also occurs, to the extent of a 50 per cent loss in their weight within three months. A further result can be observed in males, for in these, when they are in breeding condition, there develop so-called 'gloves', consisting of closely-set pigmented spines which appear in three clearly-defined stages, first on the skin covering the digits and metacarpals, then over the radio-ulna and lastly over the humerus as far as the axilla. Hypophysectomy of the 'fully-gloved' male results in complete loss of the 'gloves' in five to fifteen days after the operation, although they can be maintained in existence by the injection at frequent intervals of suitable doses of gonadotrophins. That the pituitary exerts this effect through the gonads, possibly by stimulating the production of an androgenic hormone, is shown by the fact that castration also results in the loss of the 'gloves', and that these cannot, in the absence of the gonads, be maintained by gonadotrophin injections.

Gonadotrophins from various sources (for example, anterior lobe of the pituitary, or pregnancy urine) will, if given in sufficiently large doses, affect both sexes of *Xenopus* and bring about the release of ripe sperm and ova, the male being more sensitive in its response than the female. In this way a supply of tadpoles can be obtained throughout the year, and Dr. J. M. Dodd, in his account of recent work on their metamorphosis, described the extensive observations which he has made in order to establish satisfactory techniques for the use of this very convenient material for purposes of assay. The effects of food and temperature on growth and metamorphosis of the larvae were considered in some detail, and it was shown that foods of vegetable origin are virtually inactive in producing growth, provided that the water is changed regularly so that decomposition products are removed and micro-organisms not allowed to develop. The ciliary feeding habits of the larva make it convenient to use liver powders as food, but it appears that these may contain widely varying amounts of a 'metamorphic principle' (presumably organic iodine), so that metamorphosis under fully controlled experimental conditions may be induced in some cases in as little as ten days, whereas in other cases no metamorphic signs are visible even after 260 days. The effect of temperature on growth and metamorphosis was also considered, and it was shown that, contrary to previously accepted practice, large metamorphically-retarded larvæ suitable for assay work can best be reared at a temperature of 15° C.

The practical value of such studies was shown when Dodd described his procedures for assaying by immersion and injection, and explained the use which can be made of thyroidectomized tadpoles, for he has been able to compare the metamorphic potency of L-tri-iodothyronine and L-thyroxine, to assay thyroid powders from lower vertebrates, to examine the iodine content of blood serum from patients suffering from various disorders of the thyroid, and to assay minute quantities of thyrotrophic hormone.

In conclusion, he referred to the discovery in the neighbourhood of St. Andrews of a population of the newt, ***Triturus helveticus***, in which five specimens were found to be neotenous and to show extensive enlargement of the thyroid glands. He suggested that these goitres might well be due to the action of goitrogens from yellow turnips growing in the vicinity, and expressed the hope that others might look for similar populations elsewhere, since this condition is unique in the literature and has not so far recurred in the St. Andrews population.

The Thyroid in Vertebrate Evolution

In the last paper of the session, Prof. E. J. W. Barrington discussed the thyroid gland in relation to vertebrate evolution, with particular reference to some problems of teleost endocrinology which are under investigation at Nottingham. Goitres have long been known to arise in trout which lack an adequate supply of iodine, and it is now well established that chemical goitrogens will cause hyperplasia and hypertrophy of the thyroid in teleosts similar to the effects produced by them in mammals. There is much evidence that the production of thyrotrophic hormone by the teleost pituitary is the agent in this response, and Barrington and Matty have been able to identify the cells which actually produce this hormone in the minnow. They are found to be cyanophils, positive to the McManus – Hotchkiss periodic acid – Schiff (PAS) reaction, which are coloured by the aldehyde-fuchsin stain of Gomori and Halmi, and the situation bears a striking resemblance in detail to that already known to exist in the mammalian pituitary.

These results, taken in conjunction with the work of Atz in the United States, indicate that already in teleosts the pituitary – thyroid relationship is established in an essentially mammalian form, and this suggests that from an early stage in vertebrate evolution the thyroid may have had an important part to play in adaptation to the external environment and to its seasonal changes. In considering the nature of this role, there is little positive evidence for an involvement of the thyroid in the stimulation of metabolism in fish. Although there are several reports of gonadal regression resulting from the immobilization of the thyroid by thiourea, it is not clear that this effect is actually mediated through that gland, for it has been found that minnows can complete spermatogenesis during winter, under the stimulus of artificial light, when the thyroid is immobilized by a different goitrogen, thiouracil. However, evidence is accumulating from various sources that fluctuation of thyroid action occurs in correlation with the phases of migration and spawning in certain teleosts, and the future may well show that it is the function of this gland to provide support at these periods of physiological stress or, as Hoar has argued, to activate the nervous centres which set off the characteristic appetitive behaviour associated with them.

Little time was available for discussion; but the papers alone made it clear that the field of comparative endocrinology, now attracting a welcome and rapidly increasing attention, offers scope for extensive cultivation. It is evident, too, that a satisfactory grasp of the principles of functioning of endocrine systems demands careful investigation of the problem of how far these systems have been subjected to functional changes in response to the changing stresses which the major groups of animals have encountered in extending their conquest of their environment. E. J. W. BARRINGTON

OBITUARIES

Dame Janet M. Campbell, D.B.E.

THE gratifying reduction of maternal mortality which has occurred in the past decade is largely due to the scientific discoveries of the sulphonamide drugs and the antibiotics which inhibit the organisms responsible for puerperal sepsis. Again, in the reduction of infant mortality these preparations are of service; and the advances made in biochemistry, especially in the discovery of vitamins, enable children to be brought up on sound principles of nutrition, as demonstrated by the special arrangements made for the diet of mothers and children during the Second World War.

Equally, however, merit must be assigned to the administrative pioneers in maternity and child welfare, who made it possible for these triumphs of research and knowledge of the best methods for the care of mothers and the nurture of children to be applied in British homes. Among these pioneers, Dame Janet Campbell, whose death occurred in London on September 27, takes high place.

Janet Mary Campbell was born in 1877, daughter of George Campbell, of Barnham, Sussex. She studied at the London School of Medicine for Women, graduating M.B., B.S. in 1901, proceeding to M.D. in 1904, and to M.S. in 1905 in the University of London. After holding hospital appointments, she became an assistant school medical inspector under the London County Council in 1905. In 1908 she was appointed a medical inspector of the Board of Education. Much voluntary work by suitable infant nurture and feeding had been done first in France and afterwards in Great Britain to combat the high rates of infantile mortality; but the rates were stil high in industrial towns. It was time for the State to take legislative action. The Board of Education in 1907 was empowered to give grants-in-aid for educational work in infant welfare and later for 'Schools for Mothers'. Sir George Newman, the chief medical officer of the Board, assigned the medical direction of this work to Dr. Janet Campbell. She made valuable suggestions which were incorporated in official memoranda, and undertook extensive tours throughout England and Wales to impress the need for infant welfare on local educational authorities. At this time also Sir Arthur Newsholme's important reports influenced the Local Government Board to stimulate local authorities by State grants to provide a maternity and child-welfare service. The establishment of the Ministry of Health in 1919 with Dr. Campbell as the senior medical officer of the Maternity and Child Welfare Branch and similar rank in the Board of Education integrated medical administrative work in Whitehall on this subject.

At the Ministry of Health, Dame Janet and her able staff did excellent work. In addition to serving on a number of important Government committees, including the War Cabinet Committee on Women in Industry, the Committee on the Training of Midwives and the Committee on Maternal Mortality, she served on the Health Committee of the League of Nations and rendered valuable service to international maternity and child welfare work during 1930–36. She also wrote a number of searching reports on her special subject. These led to many important reforms which have helped to reduce maternal and infant mortality in recent years.

She was created a D.B.E. in 1924, received the honorary degree of doctor of hygiene of the University of Durham, and was a justice of the peace for Surrey and for Gloucestershire. On her retirement in 1934 she married Mr. Michael Heseltine, registrar of the General Medical Council; he died in 1952.

Dame Janet was tall and good-looking. A somewhat reserved manner cloaked her enthusiasm for the cause to which she devoted her life, but those who knew her and worked with her fully appreciated her great qualities. ARTHUR S. MACNALTY

Mr. A. de C. Sowerby

ARTHUR DE CARLE SOWERBY, who died in Washington, D.C., on August 16, was a member of that branch of the Sowerby family which included such well-known scientific figures as James Sowerby, the artist-naturalist of "English Botany" fame, and James de Carle Sowerby, who was first secretary of the Royal Botanic Gardens in Regent's Park, London.

Arthur de Carle Sowerby was born in 1885 at Taiyuan-Fu, Shansi, and during an adventurous career accomplished much to promote the study of China's natural history, both as an explorer and as a writer. Among the expeditions in which Sowerby took a prominent part was a trip to Shansi and the Ordos Desert in 1908, with Mr. Malcolm Anderson, who was collecting mammals for the British Museum under the auspices of the Duke of Bedford's Zoological Exploration of Eastern Asia. This venture was successful and resulted in many new forms of mammals being collected and sent to the British Museum, where they were duly described and reported upon. In 1909 Sowerby, in the capacity of naturalist, accompanied Mr. Robert Sterling Clark to north-western China, and thereafter, up to the end of 1917, he travelled in northern and eastern China, Inner Mongolia and Manchuria, collecting on behalf of the United States National Museum in Washington.

These journeys and their scientific results have been described by Sowerby in the travel-books which he published between 1912 and 1930. Thus, the Clark Expedition was described in "Through Shên-Kan" (1912), written jointly with R. S. Clark. Perhaps the most important of these works by Sowerby is his "Naturalist in Manchuria", published in five volumes between 1922 and 1930, containing an account of the vertebrate and invertebrate fauna of the region.

In 1911 he organized and led the Shensi Relief Expedition during the Chinese Revolution, a mission which was successfully carried out after a journey of 2,000 miles.

After the First World War, Sowerby returned to China and busied himself with further explorations and collecting work in Fukien Province, and later made a biological survey of the country accessible from Shanghai.

In 1923 he founded the *China Journal of Science and Arts*, of which he was the editor for fifteen years. This valuable journal was a noteworthy contribution to cultural activities in Shanghai. It continued until 1941 and contains much valuable material on the natural history and antiquities of China, "handled", as Sowerby himself has expressed it, "in a more or less popular, but at the same time thoroughly authentic way".

He was also associated with the Shanghai Museum of the Royal Asiatic Society, becoming later honorary director of the Museum and president of the North China Branch of the Society from 1936 until 1940. He also helped to found the China Society of Science and Art, and the Numismatic Society of China, of which he was president. He was also president of the Naturalists' Club of Shanghai, founded in 1935, and to which he delivered the first presidential address, taking as his subject the "Progress of Biological Work in China".

He contributed many articles to scientific journals, newspapers, and to the *China Journal*. During 1943–49, the Heude Museum of Shanghai published several of his papers, the most considerable of which were probably his account of the birds of the Shanghai area, and a review of the mammals of the Japanese Islands, both of which were published in 1943.

Sowerby was interned by the Japanese in 1944, and when released, made his way *via* England to the United States, where he finally took up residence, in Washington, D.C. At the time of his death this genial and many-sided man was engaged upon a history of the Sowerby family, which he entitled "The Sowerby Saga". This was written in collaboration with his wife and a cousin, and the first three mimeographed parts appeared in 1952. In the first two parts of this work the origin and early and middle history of the Sowerby family are discussed, while the third part begins the story of Arthur de Carle's own life and activities down to 1912. It is to be hoped that it will be found possible to publish a further instalment of this vivid and interesting narrative. A. C. TOWNSEND

Mr. Talbot Peel

MR. TALBOT PEEL, whose death at the age of eighty-two occurred at Cambridge on September 17, had been a Fellow of Magdalene College for some forty-five years. Born on July 4, 1872, he was the son of Norris Peel, of Stonegarth, Huddersfield.

From Huddersfield College he proceeded to Magdalene College, where he was fifth Wrangler in the Mathematical Tripos (1893) and placed in the first class of the Mechanical Sciences Tripos (1894). He then went to C. A. Parsons, Ltd., Newcastle upon

Tyne, for a period of training in practical engineering, in particular on steam turbines, which were then in the early stages of development. He returned to Cambridge to take up a teaching post at the Leys School. Later he joined the staff of the Engineering Department of the University and, in 1909, was elected a Fellow of Magdalene College. Here he was director of studies in mechanical sciences and, for many years, bursar and steward, offices which he filled with enthusiasm and distinction. He was appointed to the Hopkinson lectureship in applied thermodynamics in 1930 and occupied that post until he reached the retiring age.

Peel's interests were by no means confined to the academic sphere; for example, he represented the University on the Borough Council for eleven years, was a member of the General Committee of Addenbrooke's Hospital and also served on the Finance Committee of the Evelyn Nursing Home.

His long connexion with the University and City of Cambridge was marked by never-failing courtesy and gentleness, characteristics which endeared him to all those with whom he came into contact. He is survived by his wife Elsie, *née* Penman, whom he married in 1914, and by their daughter Elizabeth.

J. TREVOR SPITTLE

NEWS and VIEWS

Atomic Energy for Peaceful Purposes

ON September 6, President Eisenhower announced that agreement had been reached between the United States and six other nations to establish an international agency which would foster the growth and spread of the new atomic technology for peaceful purposes. Atomic materials would be set aside for projects sponsored by the agency, and when arrangements were complete the United States would establish a reactor school to train representatives of friendly nations in the skills needed for their own atomic purposes. The United States was about to negotiate with the Belgian Government on the building of an atomic power reactor in that country, and discussions with Canada and with other countries that intended to build their own research reactor units would follow. President Eisenhower expressed the hope that no nation would stand aloof from such co-operation. Since then, at the General Assembly of the United Nations, Mr. Leslie Pearson, the Canadian Foreign Minister, on September 23 said that Canada believed that even without Soviet participation an international atomic agency along the lines proposed by President Eisenhower could usefully be formed, and Mr. Dulles, the American Secretary of State, affirmed the determination of the United States to implement the proposals originally made by President Eisenhower on December 8, 1953. Mr. Dulles indicated that it was now proposed to create an international agency the initial membership of which included nations from all regions of the world; to call an international conference next spring, under the auspices of the United Nations, to consider the whole subject; to open next year in the United States a reactor-training school where students from abroad might learn the working principles of atomic energy with specific reference to its peace-time uses; and to invite medical and surgical experts from abroad to participate in the work of American cancer hospitals, in which atomic energy techniques were among the most hopeful approaches to the control of this disease. No nation would be excluded from participation in this venture. On September 26, the State Department published without comment twelve notes, memoranda and aides-mémoire, exchanged in Washington and during the Berlin Conference in February between the United States and the Soviet Union, giving details of President Eisenhower's proposals of December 8, and showing how the two countries failed to reach agreement, but were still willing to continue the negotiations.

Journal of Nuclear Energy

RESEARCH work in the field of nuclear energy is now being carried out in many national establishments throughout Europe. Much of this work is of interest to nuclear physicists in general, but has perhaps tended to remain unpublished because of its specialized technical nature. The appearance of the quarterly *Journal of Nuclear Energy*, edited by J. V. Dunworth, J. Guéron and G. Randers, will therefore be welcomed not only by members of the official organizations, among whom it will circulate technical information, but also by many others with an interest in the experimental possibilities of nuclear reactors (London: Pergamon Press. Single issues 25*s*.; annual subscription, 4 issues, 90*s*.). The articles in the first number of the new *Journal* justify the claim of the publishers that it will "provide an outlet for papers dealing with the scientific, engineering, biological and economic aspects of nuclear energy". All these are represented, and at least two of the articles, those by C. A. Rennie on "Economic Power from Fast Breeder Reactors" and by J. F. Loutit on "Protection against Ionising Radiation", are of wide general interest. Although most of the papers in the first number come from Harwell, contributions from Kjeller (Norway) and Saclay (France) are included, and all are of a high scientific standard. The layout of the new *Journal* is attractive, and the printing and illustrations are of good quality; it deserves a wide circulation.

Communications and Electronics

A NEW British technical journal was launched in September under the title *Communications and Electronics*; it is intended to present monthly a review of the new practical applications of communications and electronic techniques, which are rapidly becoming one of the major industries in Great Britain. The purpose of this new journal is well illustrated in an introductory article in the first issue, by Sir Walter Puckey, who states that "the aim is to show other specialists what telecommunication and electronic systems can do, rather than how they work". Bearing in mind that these techniques are nowadays applied over a very wide range of industry and commerce, as well as to medicine and almost every field of research, this new publication may well fill a long-felt need. The scope is illustrated by the series of articles in the first issue. These deal on the radio side with such subjects as navigational aids in civil aviation, telecommunications at London

Airport, safety at sea, radio and allied techniques on British Railways, and with the present and future of colour television. Other articles provide a review of the present position of transistors, and of the significance of automatic computation in research, industry and commerce. There are also interesting sections of this issue dealing with "Electronics in Action" and "New Equipment and Components". The presentation and layout of the journal, with its excellent photographs, diagrams and explanatory charts, are of a high standard, and are a credit to the publishers, Heywood and Co., Ltd., Drury House, Russell Street, London, W.C.1; it is only available by annual subscription of £1 10*s*. for twelve issues, post paid (6 dollars in the United States and Canada).

Agriculture: Diamond Jubilee Number

STARTING as a quarterly publication in 1894, *Agriculture*, the now monthly journal of the Ministry of Agriculture, has maintained an unbroken and increasingly useful service to the farming community of England and Wales. Both the scope and influence of the journal have widened considerably since it first began, and it is now regarded as an authoritative source of scientific and practical information for farmers, market gardeners and fruit growers alike. The journal celebrated its diamond jubilee last September and the number for that occasion (London: H.M.S.O. 1*s*. net) contains various articles of interest, each contributed by specialists in the subject. The underlying theme is the progress made during the past sixty years in such fields as plant and animal nutrition and breeding, crop protection, horticulture and mechanization, and it is hard to realize how comparatively recent are many of the accepted practices of to-day. Other articles describe the changes that have taken place in Welsh agriculture, landownership and rural social conditions, while contributions of a more general nature deal with agricultural research, climate and the part played by agricultural societies, press and radio. Many readers will enjoy the personal touch provided by "I remember", a miscellany of recollections by some members of the older generation, and the beautiful illustrations depicting the varied nature of the English farming countryside.

Phyto-Sanitary Convention for Africa South of the Sahara

THE member governments of the Commission for Technical Co-operation in Africa South of the Sahara (Belgium, France, the Federation of Rhodesia and Nyasaland, Portugal, the Union of South Africa and the United Kingdom) have signed in London a Phyto-Sanitary Convention for Africa South of the Sahara. The objects of the Convention are to prevent the introduction of plant pests and diseases and other enemies of plants into any part of Africa south of the Sahara, to eradicate or control any that are at present in the area and to prevent their spread. It has established an Inter-African Phyto-Sanitary Commission on which each of the participating governments will be represented, and each participating government, as may be considered necessary by the Commission, will be required to exercise control of plant importations, and to apply measures of quarantine certification and inspection. It will also take any necessary action to deal effectively with diseases, insects, pests and other enemies of plants which have become or are likely to become a serious danger within the area, and to prohibit the importation of any plant material, seed or packing material which the Commission considers should be refused admittance into the area. The Commission is to have a scientific secretary and there is to be set up in London a Permanent Committee of Information consisting of the directors of the Commonwealth Institutes of Entomology and Mycology and the Scientific Secretary. This Committee will act as an intermediary between the two Commonwealth Institutes concerned and the African Phyto-Sanitary Commission for the transmission of relevant information about diseases, etc. The Convention will come into force as soon as it has been ratified.

Commonwealth Oceanographic Conference

A COMMONWEALTH Oceanographic Conference is to be held in the National Institute of Oceanography at Wormley, near Godalming, Surrey, during October 18–22. Australia, New Zealand, Canada, India and Pakistan are sending representatives, and observers will be attending on behalf of South Africa and Ceylon. Delegates from the United Kingdom will include representatives of the many government departments and scientific bodies interested in oceanographic research. The Conference has been arranged on the initiative of the National Oceanographic Council, to consider the possibility of closer co-operation in oceanographic research throughout the British Commonwealth. The need for such co-operation has become more pressing in recent years, as the tendency in oceanography has been to devote more and more effort to theoretical studies in an attempt to understand the fundamental physical and biological processes which are responsible for and cause variations in the properties of the waters, rather than to collect and analyse data concerning the water movements, temperature, chemical properties, distribution of marine life, etc., formerly the main activity. This change in approach has increased the difficulty of oceanographic laboratories in finding sufficiently qualified staff and providing the necessary facilities. The problems to be solved call for the attention of physicists of the highest calibre, and it will be a long time before any single country can interest an adequate number of such men in marine problems. Furthermore, it is becoming increasingly expensive to build, equip and operate a marine ocean-going research vessel. It is hoped that, as a result of the Conference, conclusions will be reached on the degree to which it is desirable for the Commonwealth countries to co-ordinate their oceanographic research programmes and to collaborate in solving outstanding fundamental problems.

City and Guilds of London Institute

THE growing importance of the City and Guilds of London Institute, and the part that it plays in advancing the cause of technical education, is the happy outcome of the enterprise of the Corporation and the Livery Companies of the City of London, which in this matter are acting fully in accordance with the tradition and past history of their respective organizations. In 1953 the Institute celebrated the seventy-fifth anniversary of its incorporation. Its progress during 1953 is described in the annual report, which contains an account of the successful launching of an appeal for £100,000 in order that the Institute could more readily meet increasing demands by industry and commerce. One of the outstanding events of 1953 was an unexpected rise in the number of candidates who sat for the City and Guilds examinations. The steep rise over the years 1941–50 was followed by only moderate increases in 1951 (834) and 1952 (1,479). In 1953 there was a sharp increase of 4,336, the number being fairly evenly spread over most established subjects.

Another important development in 1953 was the establishment of a new examining body provisionally entitled the Joint Examinations Board for the General Certificate of Education. This body will offer examinations having a bias towards the particular needs of pupils in secondary technical, commercial and modern schools and classes and the needs of students in institutions for further education. The Institute has undertaken, during the initial stages, the administrative and financial responsibilities of the Board, of which it is one of the sixteen sponsoring bodies.

Properties of 'Nimonic 95'

A RECENT addition to the well-known series of 'Nimonic' alloys is discussed in a technical publication of Henry Wiggin and Co., Ltd., Thames House, Millbank, London, S.W.1. The highest creep resistance is normally obtained by solution-treating the alloy for 4 hr. at 1,150° C., or, if a coarser grain size is not a serious matter, for 1–2 hr. at 1,200° C. This is followed by reheating for 6–8 hr. at 1,080° C., followed by 16 hr. at 700° C. In each case the sample is air-cooled after the treatment. Among the high-temperature properties which are given, the 0·1 per cent proof stress, which is 51 tons/sq. in. at ordinary temperatures, is still 43 tons at 700° C., 17 at 900° C., and 4·1 at 1,000° C. The corresponding figures for the elongation per cent, measured on four times the square root of the area, are 25, 4·5, 11 and 59, the modulus of rigidity being 30, 25, 18 and 14 × 10^6 lb./sq. in. At 870° C. the endurance under a stress of 20 tons/sq. in. is 10 × 10^6 cycles, and at 16·8 tons 45 × 10^6 cycles in about 300 hr. Among the creep data given the following figures may be mentioned: under a stress of 8 tons/sq. in., a creep extension of 0·2 per cent occurs in 10,000 hr. at 750° C., at a stress of 7·5 tons at 815° C. in 1,000 hr., and under a stress of 4 tons/sq. in. in the same time at 870° C. Rupture under creep in 1,000 hr. occurs under stresses of 16, 8·5, 5·5 and 2·2 tons/sq. in. at temperatures of 750, 815, 870 and 925° C. respectively.

Gamma-Ray Sources for Radiography

A REVISED second edition of the "Memorandum on Gamma-Ray Sources for Radiography", first published in 1952 (see *Nature*, 170, 186; 1952), has recently been issued (pp. 28. London: Institute of Physics, 1954; 3*s.* 6*d.*). As previously, it has been prepared by a committee of the Non-destructive Testing Group (formerly the Industrial Radiology Group) of the Institute of Physics. The physical characteristics of gamma-ray sources, with particular reference to the products of the Atomic Energy Research Establishment, Harwell, and of the Radiochemical Centre, Amersham, are summarized, and attention is directed to radiographic technique, protection of personnel and to the costs involved. The subject-matter has been brought up to date and has been extended in many respects, particularly with regard to the number of radioactive materials considered. For industrial radiography, sources consisting of the naturally radioactive gas radon-222, which is of high activity and small bulk, and cæsium-137, can be obtained from Amersham, and artificially radioactive sources—cobalt-60, tantalum-182, iridium-192 and thulium-170—from Harwell; in addition, the shorter-lived sodium-24 and gold-198 sources can be supplied from Harwell when specially ordered. One section of the memorandum deals with the sizes of sources and the design of source capsules, and in another an outline of gamma-ray radiographic technique—which, it is pointed out, is similar to that of X-rays—is given with references to further details. Other sections deal with the protection of personnel, the handling and transport of sources and the cost of installing equipment for gamma-ray radiography. The memorandum concludes with a comprehensive and useful bibliography and with data sheets for each of the longer-lived radioactive sources mentioned above. The data are reproduced from official sources.

Cotton Growing in Northern Nigeria during the Season 1952–53

THE progress report for the season 1952–53 from the Experiment Stations in Northern Nigeria of the Empire Cotton Growing Corporation (pp. 19. London: Empire Cotton Growing Corporation, 1954; 9*d.*) reports that, following the previous season's record yield of 113,510 bales of cotton, 17 per cent more seed was issued, although not all was planted, and some, which was taken by inexperienced cultivators, gave very little return. Early rains made cotton planting unduly late, and confidence induced by the easily obtained good yields of the previous crop led to less attention to planting and weeding. In consequence, the crop for export was only 95,445 bales, and the average return per ton of seed fell from 10 to 7 bales of lint. At Samaru, in Zaria Province generally and in some other areas yields were as good as in the 1951–52 season; the growth of the industry in the Gombe area (Bauchi Province) has been remarkable and is clearly capable of expansion. Yields in South Katsina were well below those of the previous season. Rainfall at Samaru was unusually heavy in July, well below normal in August, and about normal in total and in time of cessation (October). The growth of the crop was in general satisfactory. Insect damage was not unduly severe, that attributed to mirids (*Campylomma* and/or *Lygus* spp.) being less than in the two previous seasons. Red bollworm populations were lower except at Kontagora and Yola, and pink bollworm was higher than elsewhere at Yola and Gombe. Good control of *Campylomma* and a marked reduction in leaf tattering was achieved at Samaru by late spraying with 1 per cent DDT emulsion, and at Daudawa treatment with DDT emulsion gave a 50 per cent increase in the yield of clean seed cotton. Bacterial blight (*Xanthomonas malvacearum*) was more in evidence than in 1950–51 or 1951–52, and it seems probable that this disease in its several manifestations can be responsible for much damage to bolls, although differences between strains in the severity of symptoms displayed are not related obviously to differences in yield.

Manganese and Metabolism in Potatoes

THE importance of manganese in plant metabolism, though now established, is but little understood. In a study of the effect of manganese on the assimilation and respiration-rate of isolated rooted leaves of the potato, H. C. Ruck and B. D. Bolas (*Ann. Bot.*, N.S., 18, 71, 267; 1954) have found that normal potato leaves will root readily after treatment with α-naphthaleneacetic acid (2 p.p.m.) but that very few manganese-deficient leaves will respond in this way, the critical level being about 15 p.p.m. manganese on a dry-weight basis. The growth of the manganese-deficient leaves was also less, but they did not develop the characteristic symptoms of this mineral deficiency, even when the level had fallen below that at which symptoms would have appeared on attached leaves. In leaves which had a high or a low manganese content at the time of rooting there was a marked difference in the net assimilation-rate; but the addition of manganese after rooting to leaves of low content did not increase the assimilation-rate. The effect of manganese content on respiration was found to be slight, though a higher respiration-rate was consistently associated with a higher manganese content. No effect on translocation was detected. The authors point out that the effect of manganese on the assimilation apparatus may occur during the development of the leaf and that once the chloroplast system has become fully developed any manganese deficiency which develops during that phase cannot afterwards be made good. They also indicate, however, that the capacity for chlorophyll formation in deficient leaves is not lost, since considerable greening can be produced by injection, provided the manganese deficiency has not become too advanced.

The National Museums, Ceylon

THE administration report of the National Museums, Ceylon, for 1953 records the activities at Colombo, Kandy, Ratnapura and Jaffna. It is interesting to note that at the Colombo National Museum an annual attendance of 207,438 included 35,171 schoolchildren in organized groups. The acquisition of the only known incisor tooth of *Rhinoceros sinhaleyus* and a series of bone implements, including some notched for attachment to hafts from cave deposits, is reported. On the proposal of the Director, the Colombo Museum Committee decided to conduct a speleological survey of Ceylon to include the zoology and prehistory of all the caves in the Island. Accordingly, a Speleological Association of Ceylon, the membership of which is open to the public, was formed in July 1953.

Swedish National Committee for Physics

THE seventh general physics conference of the Swedish National Committee for Physics was held at he Chalmers Institute of Technology, Gothenberg, during September 28–30, 1953. The director, Prof. Nils Ryde, gave details of the facilities available at the Institute and described the research work in progress, and Prof. S. Eklöf spoke about the organzation of teaching and research in the Electrical Engineering Department. Several distinguished visitors from outside Sweden attended the conference and gave addresses. These included Dr. M. Edlund (Oak Ridge Laboratories), who gave a survey of recent reactor developments in the United States; Prof. T. W. Bonner (Rice Institute, Houston), who lectured on excited states of light nuclei; and Dr. A. Bohr and Dr. T. Huus (Copenhagen), who spoke about rotational states of atomic nuclei and the Coulomb excitation of heavier atomic nuclei, respectively. Summaries of the other forty-six papers contributed to the conference are printed in *Arkiv för Physik*, 8, 1; May 1954. They include several contributions from the Atomic Energy Laboratory, tockholm, and from the Nobel Institute of Physics, tockholm.

The Nature Conservancy: Awards for 1954

THE Nature Conservancy announces the following awards of research studentships for postgraduate training in ecology, tenable for periods of up to three years at the universities and other institutions named: *Botany:* A. P. Hughes (Trinity Hall, Cambridge); E. Lodge (University College, London); N. M. Pritchard (Balliol College, Oxford); T. O. Pritchard (Leeds); V. I. Stewart (Aberdeen). *Zoology:* J. M. Colebrook (Freshwater Biological Association, Far Sawrey, Ambleside); J. C. Coulson (Durham); J. B. Ford (Southampton); Miss T. J. White (Imperial College of Science and Technology, London).

Announcements

THE Council of the Royal Society has appointed Prof. M. L. E. Oliphant, of the Australian National University, as the Rutherford Memorial Lecturer for 1955. Prof. Oliphant will deliver lectures in India and Pakistan.

THE 1954 Eddington Lecture is to be given in Cambridge, at the Arts' School Lecture Theatre, Bene't Street, on November 2, at 5 p.m., by Prof. H. Dingle, professor of the history and philosophy of science in University College, London. Prof. Dingle will speak on "The Sources of Eddington's Philosophy".

THE War Office announces that Prof. S. J. Davies has been appointed dean of the Royal Military College of Science, Shrivenham. Prof. Davies is professor of mechanical engineering in the University of London at King's College, and will retain his chair until the end of the present academic year.

DR. E. H. SONDHEIMER, lecturer in mathematics in the Imperial College of Science and Technology, London, has been appointed to the University readership in applied mathematics tenable at Queen Mary College, University of London.

THE Metallurgical Laboratories of the British Welding Research Association are holding open days on November 23 and 24. Admission will be by ticket, obtainable from the Secretary, British Welding Research Association, 29 Park Crescent, London, W.1.

REFERRING to the article on "The Golgi Apparatus" (*Nature*, July 3, p. 21), Mr. Dennis Lacy writes: "I may inadvertently have given the impression that the views of Dr. J. R. Baker and his colleagues are based solely upon the study of only three different cells (neurones of *L. migratoria*, epithelial cells of the intestine, and Paneth cells). They have indeed published careful accounts which deal specifically with the Golgi problem in nineteen different kinds of cells".

ERRATUM. In the article on the report for 1953 of the Rothamsted Experimental Station (*Nature*, September 11, p. 498), referring to the work of the Bee Department, it is said that the fumes produced by adding small quantities of ammonium nitrate to burning smoker fuel provide a simple anaesthetic for use when transferring bee colonies from one site to another a short distance away, since on recovery it is claimed that the bees lose their tendency to drift back to the original site. It should have been added that the Rothamsted work has failed to substantiate this claim, but it is considered that the method, provided that the minimum proportion of ammonium nitrate to fuel is used, is the most efficient and simple one so far suggested for anaesthetizing whole colonies of bees *in situ*.

USE OF SCIENTIFIC DEVELOPMENTS IN INDUSTRY

TWO papers given before Section F (Economics) of the British Association at Oxford on September 7 supplemented the account of the work of the Science and Industry Committee included in the first report of the Committee on Human Relations in Industry issued last June (see *Nature*, 174, 49; 1954). In the first of these, Prof. C. F. Carter gave a brief account of the way in which the interest taken in the work of the committee originally set up by the Council of the British Association at the Belfast meeting in 1952 to study "the problems of speeding up in industry the application of the results of scientific research" had led last spring to the reconstitution of the committee under the joint sponsorship of the British Association, the Royal Society of Arts and the Nuffield Foundation. Prof. Carter, emphasizing that the situation is changing and requires constant reassessment, explained the way in which the Committee has sought both to obtain an overall view of the relative importance and the inter-relations of the various factors and of the way in which it operates in particular firms. It has attempted, for example, to collect further information as to the validity of the view that British industry is inadequately supplied at the higher management or directorate level with persons with scientific and technical knowledge, and to elucidate the question whether the use of scientific knowledge is being impeded by restrictive practices on the part of management, the latter with the view of weakening or strengthening the suspicion that it does not pay to be quick in exploiting new scientific discoveries or methods.

The first year was spent in preliminary planning, in securing funds and in recruiting staff, and Prof. Carter did not attempt to give an interim report on the Committee's conclusions even during its second year's work. He remarked that certain possible hindrances to the use of science which *a priori* looked important have obstinately failed to appear in the case studies so far conducted. The attitude of industry to science is unlikely to be the mechanical result of a set of material factors. While such matters as the shortage of scientists or of equity capital, the influence on investment of the size of firms, or the proportions of management with certain qualifications, though very troublesome to investigate, can be reduced to questions of fact which are precisely defined, at every point questions of fact are inextricably mixed with those of attitude. The demand for scientists, for example, depends on the attitude of different types and sizes of firms as to the usefulness of employing scientists, and this depends on a general climate of opinion. So, too, the effect of taxation on the utilization of scientific knowledge is the resultant of the different ways in which the same taxation system causes different people to act; nor did Prof. Carter venture to predict how much the Science and Industry Committee could add to knowledge on a matter which involves these puzzling problems of attitude.

Prof. B. R. Williams's paper explained the methods employed by the Committee in the studies it has sponsored of the action of particular firms facing particular opportunities in new applications of science. Like Prof. Carter, he emphasized the willingness of firms to co-operate and the great interest taken everywhere in the work of the Committee. Following a first attempt to obtain information on the origin of both successful and unsuccessful developments, the difficulties encountered and the time scale as well as, for new products, the particular sales problems, the Committee hopes to investigate more fully some fifty firms with the view of obtaining further insight into what determines the rate at which new products or processes are created and taken up. For this purpose a rough classification of problems has been attempted into those of communication and conversion generally, those due to the structure of the relevant industry, and those due to the structure of British industry.

Only one inquiry is almost complete at this stage—that into the rate at which, and means by which, tunnel kilns and kiln furnitures have been improved in the pottery industry. Here tunnel kilns which, when working properly, give significant savings of fuel, labour and wasted ware and facilitate the flow of work within the factory, were taken up very slowly until after the War, since when a large number had been installed. Prof. Williams said this can be attributed to four main factors. The pottery industry is in large measure a craft industry with a craft attitude to the job as a whole and great suspicion of new-fangled methods. Costing methods are primitive or non-existent. The large amount of space required by tunnel kilns involves extensive building, and this is a great impediment when output is not expanding and profits are very low. The small firms predominating in the industry have difficulty in financing rebuilding and installation when profits are low, and are reluctant to raise capital in a way that endangers family succession. The increased installations since the War can be traced to the breakdown of some of these impediments.

Commenting generally on the investigations, Prof. Williams stressed the value of such inquiries sponsored by a body constituted like the Science and Industry Committee. The Committee has facilitated deployment of the expert knowledge and experience of its members without subjecting them to intolerable strain. The method employed in the second stage inquiries works best with firms that have squarely faced the application of science to industry, and particularly with firms large enough to maintain an organization for that purpose. He emphasized the need for caution in generalizing direct from the peculiar conditions of the post-war period and also in judging whether a firm is reasonably fast or unreasonably slow in the industrial application of science. The firm which most impressed him with the speed and whole-heartedness with which it applied science to industry had only been saved from bankruptcy recently by a manager who insisted on cutting research and development far below the level at which he found it; in consequence, the firm will probably soon be spending more on research and development than before its near bankruptcy.

ATOMIC LINE SPECTRA

IN the course of a long history, the branch of physics concerned with the study of optical spectra has been exceedingly fruitful of fundamental results and concepts, and in application. A period of remarkable advance—the golden age of the interpretation of line spectra and extranuclear atomic structure—extended over little more than ten years following the First World War. At the opening of that period, a number of significant regularities had been found empirically in, for the most part, the simpler series spectra, by diligent efforts of a number of workers subsequent to Balmer's discovery, in 1885, of the distribution law of the hydrogen line series which bears his name. In addition, Bohr had produced his postulates for hydrogen-like atoms in 1913, and calculated the Rydberg constant. However, the spectra of most elements consisted of bewilderingly large numbers of lines having little apparent order. The great achievements of the early 1920's resulted from application of the Bohr theory and its elaboration, at the hands of Bohr, Sommerfeld, Landé, Pauli, Russell and others, into the older quantum theory and vector model, and from the provision, in 1922, of the key to the analysis of complex spectra by Catalán's paper on the arc spectrum of manganese. Simultaneously, development of a theoretical background capable of co-ordinating much of the accumulated observational material stimulated vigorous laboratory investigations, aimed at improved accuracy and methods.

Later in the 1920's, the formulations of quantum mechanics removed much of the *ad hoc* appearance of the older theory. Achievement was, in fact, so rapid and extensive that, by the beginning of the decade following, the impression was widespread that study of atomic spectra had become, in essence, a closed field; correspondingly, though with notable exceptions, the vigour of laboratory investigations faded, and the number of active workers declined. The view that a particular field is exhausted of further basically important discoveries is of a risky nature; in the case of line spectra, much of fundamental interest may repay investigation of the finer details of even, at present, well analysed spectra. In some cases—for example, those of the complicated rare-earth and transuranic spectra—little more than a start has been made in analysis. Measurements of line intensities and oscillator-strengths, while of fundamental significance, are beginning to receive the attention needed largely because of the demands of the astrophysicist. A similar position is probably arising regarding Stark and other line-broadening effects, in relation to spectroscopic study of discharge plasmas. Again, interconfiguration interactions and autoionization phenomena are little understood—and the theme can be developed.

The present position and current directions of work on atomic spectra received excellent demonstration at the recent "Rydberg Centennial Conference", held during July 1–5 in the Physical Laboratory of the University of Lund. The meeting was organized, under the auspices of the International Union of Pure and Applied Physics, by the Swedish National Committee of Physics, and marked the centenary of the birth of Johannes Robert Rydberg (1854–1919). Rydberg, while holding the chair of physics at Lund, successfully applied a genius for the handling of numerical data to the search for regularities in line spectra.

The conference met under the presidency of an eminent contributor to line-analysis, Dr. W. F. Meggers, of the U.S. Bureau of Standards, and owed much for initiation and excellence of organization to Prof. B. Edlén, the present occupant of Rydberg's chair, whose work on the spectra of stripped atoms and of the solar corona is renowned. During the four days a total of more than sixty papers was read, most centres of currently active research on line spectra being well represented.

The proceedings of the first day, devoted to the general structure and analysis of atomic spectra, were distinguished by review addresses by N. Bohr (Copenhagen) on "Rydberg's Discovery of the Spectral Laws", W. Pauli (Zurich) on "Rydberg and the Periodic System" and A. G. Shenstone (Princeton) on "Series in Line Spectra". B. Edlén (Lund) discussed improvements in spectral series representation, and showed that all series in alkali arc spectra and in Ca II can be accurately represented by addition of one or two terms to the usual Ritz denominator. Present accepted values of the ionization potentials of ions up to the nineteenth stage were reviewed by W. Finkelnburg (Erlangen), who indicated improved methods of extrapolation along isoelectronic sequences. C. C. Kiess (Washington) described results of the analysis of Mo II; with the aid of new wave-length and Zeeman effect observations, 80 per cent of the observed lines are classifiable. The analyses of Os I and II, utilizing Zeeman patterns at 85,000 gauss, were discussed by J. C. van den Bosch (Amsterdam). Papers by S. Glad (Lund) and by O. Garcia-Riquelme and R. Velasco (Madrid) described work on the astrophysically important spectra of Fe III and Ni III, respectively. In dealing with complicated spectra, search for real constant-frequency intervals is extremely time consuming; in this connexion L. F. H. Bovey (Harwell) discussed the applicability of standard computing equipment to term analysis.

A number of interesting papers on methods and results of high-resolution spectroscopy were presented during the second and third days. H. Kopfermann (Heidelberg) reviewed past contributions and present trends of investigations on optical hyperfine structures and isotope-shifts in relation to nuclear properties, namely, spin, magnetic and quadrupole moments. This kind of work has always made great demands on instrumental refinement and technical skill; the elegance of some of the experimental arrangements outlined indicated that progress in these respects continues. Thus, P. Jacquinot (Bellevue, S. et O.) described a recording Fabry–Perot interferometer which employs a photomultiplier or photo-conductive detector placed behind an annular exit-slit, upon which the ring system is focused concentrically; scanning of the pattern is performed by moving the fringes across the slit, by cyclic variation of either the gas pressure in the interferometer housing or of the étalon spacing. This type of instrument has been used by H. Chantrel, who reported an investigation of the abundance-ratio of lead and neodymium isotopes and a determination of the quadrupole-moment of mercury-201, and by J. Blaise, who described results on hyperfine structure, in Pb I and II and the first measurement of a hyperfine structure pattern of a line lying beyond the photographic limit in the infra-red. Other work of high refinement consisted in combination of an atomic-beam light source and a large-gap étalon; described by K. W. Meissner (Lafayette, Ind.), this apparatus has been used to obtain wave-lengths of eight lines of germanium to an estimated ± 4 × 10^{-4} A. Successful measurements of very small isotope shifts in Sn II and Cd II were reported by H. G. Kuhn (Oxford); in this work enriched isotope samples were employed. E. Rasmussen (Copenhagen) gave results on isotope shifts in krypton; here, the isotopes, separated in a mass-spectrometer, were collected on aluminium foil from which the gas could afterwards be released by radio-frequency heating. Description of the measurement of isotope shifts in the spectra of the lightest elements by J. E. Mack (Madison) included a discussion of their interpretation in terms of the specific mass contribution. Work at Amsterdam on the spectra of plutonium-239 was described by P. F. A. Klinkenberg; high-resolution studies have led to the conclusion that this isotope has a nuclear spin of ½. High-resolution work at the Oak Ridge Laboratories of the U.S. Atomic Energy Commission, described by J. R. McNally, has included isotope-shift and abundance studies in the heavy elements and transuranics; for example, uranium-233 and 235 were stated to have probable nuclear spins of 5/2 and 7/2, respectively. Two papers were concerned with the important topic of the Lamb–Retherford shift, both being marked by the skill of the techniques employed. G. W. Series (Oxford) had studied the fine structure of He II λ4686, using two étalons in series and a discharge-tube cooled in liquid hydrogen; he reported that the results departed appreciably from Dirac theory expectations, and possibly also showed a smaller departure from predictions of the new quantum electrodynamics. G. Herzberg (Ottawa) described measurements of the wave-length of the first line of the Lyman series of deuterium; for this work, the fifth-order of a three-metre vacuum grating was employed, and the line obtained in absorption by the partially dissociated gas drawn from a Wood tube; again, there are indications that the shift of the ground-level of deuterium shows a small departure from theory.

A welcome feature of the conference was the presence of a number of prominent workers on theoretical spectroscopy—this especially since the most recent monograph available is the monumental effort of Condon and Shortley, now some twenty years old. The scope of current theory applied to actual classification problems was reviewed by G. Racah (Jerusalem), with particular mention of complex ($l^m d^n$-configuration) and very complex ($l^m f^n$-configuration) spectra. Several papers referred to features of two-electron spectra; E. A. Hylleraas (Oslo) gave results of new calculations of singlet and triplet series, and P. Pluvinage (Strasbourg) presented new results for the ground-state and first-excited state of He I. The interesting question of the effect of interconfiguration interaction in He I-like spectra was dealt with by L. C. Green (Haverford, Pa.). L. Biermann (Göttingen) reported theoretical calculations of *f*-values, and directed attention to the importance of interconfiguration perturbations; thus, in the case of the singlet resonance line of Ca I, the theoretical value of $f = 2 \cdot 2$ is reduced to 1·48 when the effect of *4pmp* terms is included.

Several papers formed general or specific reports on laboratory methods. Infra-red atomic spectroscopy was comprehensively reviewed by C. J. Humphries (Corona, Cal.) with particular emphasis on the use of modern photoconductive detectors; the certain usefulness of these techniques in the investigation of rare-earth spectra was indicated. R. A. Fisher (Evanston, Ill.) described a use of Edser–Butler fringes for facilitating wave-length calibration of recording spectrometers. Experience with the use of multilayer highly reflecting films on Fabry–Perot plates was described by F. A. Jenkins (Berkeley). In a paper on stigmatic concave gratings, F. Zernike (Groningen) proposed the novel solution of replacing the usual straight ruling by a system of concentric circular arcs. E. Hulthén (Stockholm) described experiments made with plane gratings immersed in liquids as a means of raising resolving power and dispersion. Several developments of light sources were described; for example, convenient forms of demountable hollow-cathode tubes (H. Schüler, Hechingen), the 'vacuum sliding-spark' (N. Astoin and B. Vodar, Bellevue) and the pulsed high-frequency electrodeless discharge (L. Minnhagen, Lund). All these sources are useful in the study of spectra of the lower ionization stages, the 'sliding spark' being the most energetic; the use of this source was illustrated by K. Bockasten (Lund) for O III and IV.

The study of line intensities and *f*-values was well represented. W. F. Meggers (Washington) reported measurements of arc intensities of 30,000 lines from seventy elements introduced as small admixtures in a base of powdered copper; copper lines used as intermediate intensity standards were finally compared with radiation from a tungsten lamp. Use of a King furnace at Amsterdam, for measurement of relative *f*-values of Fe I lines, was described by C. J. Bakker. The promising technique of rotation-stabilized arcs, which makes possible the realization of a portion of matter in thermal equilibrium at a temperature of up to 50,000° K., was described by H. Maecker (Erlangen). R. H. Garstang (London) reviewed theoretical computations of atomic transition probabilities, and presented the results of his own calculations and their comparison with experiment.

The final day of the conference was occupied with papers on miscellaneous experimental topics, compilations of data, and astrophysical applications. Autoionization phenomena were discussed by W. R. S. Garton (London) in connexion with vacuum ultra-violet absorption spectra. Two papers dealt with elegant experimental techniques developed at the École Normale Supérieure, Paris. A. Kastler described applications of a method involving optical detection of the partial spatial orientation produced in an atomic beam which is subjected to a perpendicular magnetic field and, parallel to this, a beam of circularly polarized resonance radiation. J. Brossel and J. E. Blamont described measurements on the Stark effect of the $6\,^3P_1$ state of Hg I, based on observation of the change in the magnetic resonance curve following superposition of an electric on the main magnetic field. Statistical Stark broadening in the spectra of discharge plasmas was discussed by W. Lochte-Holtgreven (Kiel), with particular reference to determination of ion concentrations in the high-power arcs developed at Kiel. L. Herman (Bellevue) compared experimental and theoretical contours of Balmer series lines exhibiting strong ionic Stark broadening. Use of a statistical theory, based on a Lennard-Jones potential function, was suggested by B. Vodar (Bellevue) to account for the results of experiments on the shifts of resonance lines of the alkalis, mercury and xenon, occasioned by high pressures of foreign gases. Features of time-resolved spectra of long sparks in air, and of pulsed centimetre-wave discharges in rare gases, were described respectively by A. Vassy (Paris) and by I. Eyraud and J. Janin (Lyons). Measurements of wave-length standards by means of a reflecting échelon were described by T. A. Littlefield (Newcastle), who directed attention to the necessity for certain corrections; P. Risberg (Lund) explained the establishment of accurate vacuum ultra-violet wave-length standards by application of the combination principle to newly measured long wave-length lines of Mg II and Ca II.

Mrs. C. E. Moore-Sitterly (Washington) spoke on one of the several valuable compilations of data for which all spectroscopists are indebted to her, namely, a second revision of Rowland's Solar Wave-length Table. Announcement of the preparation of a useful table of forbidden multiplets of astrophysical significance was made by J. W. Swennson (Liège). Of the specifically astrophysical papers, that of E. Finlay-Freundlich (St. Andrews) on his well-known hypothesis in explanation of the general red-shift in celestial spectra produced much discussion; the possibility of fluorescence by line-coincidence was illustrated by J. Gauzit (Lyon), and Mrs. C. Payne-Gaposchkin (Cambridge, Mass.) contributed results of a spectrometric study of a rotating star. The conference ended with a general discussion, under Prof. Edlén, concerning proposals for defining the metre in terms of the wave-length of a chosen spectral line produced under specific conditions.

Limitations of space preclude a fuller account of the many important contributions to this conference, which demonstrated that the study of line spectra continues to flourish.

RIDERLESS MICROCHEMICAL BALANCES

At the recent symposium on analytical chemistry held in the University of Birmingham by the Midlands Society for Analytical Chemistry, one of the most interesting features in the display of modern laboratory apparatus was the adoption of the riderless beam principle by the firm of L. Oertling, Ltd. (Cray Valley Road, St. Mary Cray, Orpington, Kent), in the construction of its two new microchemical balances.

There is little doubt that one of the most serious sources of error in weighing on a microchemical balance (apart from the personal factor) is associated with the use of the rider. These errors have been attributed to variations in the mass of the rider, its angular placement on the beam, the shape of the notch and the accurate location of the notches on the beam. The cumulative effect of these errors over the several weighing operations involved in a gravimetric analysis may result in considerable inaccuracy. Some workers have estimated the probable error of any one reading on a microchemical balance at ± 3 μgm., while work undertaken for the American Chemical Society by others gave values of 0·9–23·3 μgm. for the standard deviation of thirty-two different microchemical balances used with a 1-gm. load. The elimination of every possible source of error is therefore highly desirable.

Few fundamental advances have been made in the design of microchemical balances since the evolution of the original Kuhlmann model, but the elimination of the rider error in these two new microbalances by Messrs. Oertling will undoubtedly be hailed as such by many.

In place of the conventional rider system, a plain beam is used in conjunction with a series of fractional rider weights. These fractional riders are loaded on to a special carrier bar, attached to the pan-suspension system, by means of levers operated by a calibrated dial attached to the right-hand side of the balance case. In the more sensitive of the two balances, these fractional riders have a displacement value equivalent to 9 mgm., so that when the 1-mgm. range of the graduated optical scale is added, a total displacement of 10 mgm. can be observed, rendering the use of weights less than 10 mgm. superfluous.

Needless to say, the possibility of errors of another nature is introduced by the riderless beam principle, and one still has to reckon with variation in the weights of the fractional riders; but nevertheless weighing operations are speeded up considerably, and the inherent errors involved would seem to be less serious, for the manufacturers claim that for the first time in microchemical weighing it is possible to weigh with certainty to the nearest microgram.

ACTIVITIES OF THE INTERNATIONAL UNION OF BIOLOGICAL SCIENCES

The Policy Board of the International Union of Biological Sciences met in Paris during June 28–30 and made a number of recommendations regarding the future structure of the Union. The Board consisted of Prof. P. Weiss (United States) and six other members: Prof. A. Frey-Wyssling (Switzerland), Prof. J. Monod (France), Dr. L. Harrison Matthews, representing Prof. C. F. A. Pantin (United Kingdom), Prof. B. Rensch (German Federal Republic), Prof. John Runnström (Sweden) and Prof. M. J. Sirks (Netherlands); a number of officers of the Union and of other International Unions were also in attendance for parts of the meeting. One of the principal recommendations was that the Union should consist of eleven Sections, as follows: Biochemistry, Biometry, Botany, Cell Biology, Developmental Biology (including embryology), Ecology (including limnology), Genetics, Microbiology, Physiology, Experimental Psychology and Zoology (including entomology). This would involve setting up four new Sections—those of Biochemistry, Developmental Biology, Physiology and Experimental Psychology—and incorporating the present Sections of Embryology and Entomology as indicated.

The work of the Union is of a varied nature. Research institutes available to workers of all nationalities have been supported or founded: for example, a culture collection of wild species of *Drosophila* at Pavia; Centres for the Biological Control of the Pests of Plants at Geneva and Mentone; the International Depot of Microscopical Preparations at Louvain; the International Bureau of Human Heredity at Copenhagen; and the Serological Museum at Rutgers University, New Brunswick. The Union organizes and partly finances symposia for the discussion of current research (usually three a year) by small groups of specialists, and also helps in the organization of international congresses relevant to its work. Catalogues of types in national museums, and a list of type-genera and species of mites have been published, thanks to financial aid from the Union, and annual grants have been made to certain periodical publications of an international character concerned with bibliography, such as the *Zoological Record*, *Biological Abstracts*, *l'Année Biologique* and *Resumptio Genetica*; the publications of the International Commissions for Zoological Nomenclature, Botanical Nomenclature and Bacteriological Nomenclature have also been supported financially.

The officers of the Union are as follows: *President*, Prof. S. Hörstadius (Sweden); *Vice-President*, Prof. R. E. Cleland (United States); *General Secretary*, Prof. G. Montalenti (Italy); *Secretary*, Prof. R. Ulrich, France (Laboratoire de Physiologie Végétale, 1 rue Victor Cousin, Paris 5e); and *Treasurer*, Prof. A. Linder (Switzerland). Publications of the Union are available from the secretary, Prof. Ulrich. All other communications should be directed to the general secretary, Prof. G. Montalenti, at the headquarters of the Union, Istituto di Genetica, Via Mezzocannone 8, Naples.

CRYSTALLINE BACTERIAL ARRAYS AND SPECIFIC LONG-RANGE FORCES

By Dr. R. J. GOLDACRE

Chester Beatty Research Institute, Royal Cancer Hospital, London, S.W.3

THE purpose of this communication is to show that, like viruses, some bacteria can be crystallized. The bacterial cells form regular three-dimensional arrays in which each cell corresponds to a molecule in a conventional crystal; with rod-shaped bacteria, the rods are parallel.

This helps to bridge the gap between the microscopic and the molecular. For the first time it is possible to see easily with the light microscope particles which behave in some respects like molecules. This can be done when they are in their natural medium, without drying as required for the electron microscope.

There is reason to think that specific forces may operate over distances much greater than the range of ordinary valency forces. While the work of Rothen[1] remains controversial and has been to some extent disproved[2,3], it is undisputed that in suspensions of bentonite[4], solutions of tobacco mosaic virus[5] and of some other colloidal substances[6], individual particles are under certain conditions held orientated parallel to one another when the distances separating the particles are as large as several hundred angstrom units. The largest spacing so far recorded is 8000 A. in the Schiller layers of iron oxide[7]. As Bernal[8] has said: "There is evidence that between extended particles there are forces which act at distances of the same order as the size of the particles themselves". In the bacterial aggregates to be described the forces appear to operate over distances of 10,000–50,000 A. Regular arrays were obtained both in two dimensions and in three.

(*a*) *Two-dimensional arrays.* During work on *Amoeba proteus* in hanging drops of Chalkley's[9] medium—a very dilute balanced salt solution—it was noticed that fine parallel striations appeared on the surface, especially if the drops were set aside for a few days. These gave brilliant diffraction colours with the light from the condenser, and on close inspection the striations were found to be made up of thousands of parallel bacterial rods. These bacteria occurred naturally in association with the amoebæ and multiplied after the amoebæ cytolysed. Stirring with a micromanipulator disorientated the rods, but after the removal of the needle they rapidly became parallel again. This shows that the orientation was not due to adhesion of the cells after division. Small islands containing about thirty parallel rods sometimes occurred. These were in dynamic equilibrium with the free individual bacteria in the solution, which were highly mobile either due to locomotor organs or lively Brownian movement. Bacteria approaching an island were captured, and snapped parallel to the rest of the group, and others broke free from time to time elsewhere and escaped into the solution. A cell prized off by the micromanipulator by more than 5 μ from the edge of the island would swim away freely in the solution.

In regions of the surface where the cells were not parallel, they could be made to become so by stroking with a micromanipulator needle, and the influence spread far beyond the area stroked. This recalls the scratching technique used by chemists to induce crystallization in a supersaturated solution. A needle placed in the surface of the drop induced the cells to arrange themselves in palisades on each side, the orientation extending outwards for about ten rows or 40 μ before fading out. The tip of the needle by itself induced a radial arrangement, resembling an aster. Similar effects could be produced by fragments of glass, algal cells or other relatively large disturbance of the surface. When two such fragments were within about 80 μ, the appearance of the mitotic spindle was simulated. Tripolar effects could also be obtained.

The side spacing between the rods was commonly about 3 μ, compared with a cell width of about ½–1 μ and a length of 3 μ, but spacings of from one to five microns were sometimes observed with smaller and larger species. The cells were not in contact, for (1) electron micrographs showed no jelly, capsule, flagellæ or other material between them; (2) they could be pushed closer together by the micromanipulator and sprang apart when released; (3) if mobile rods of a smaller species were introduced, they swam up and down between the rows in straight lines without disturbing the structure, or being captured.

The aggregates appear to be the result of a long-range attraction and a shorter-range repulsion. Specificity is suggested by the occurrence side by side of many homogeneous aggregates of different species which separated out from a mixed suspension; and also by (3) above.

Surface tension forces probably account for some, but not all, of the interaction. Some of the effects (parallel orientation, spindles, asters) could be duplicated with human hair, chopped into 1-mm. lengths, floating on water, and by cardboard rods with alternate water-attracting and water-repelling bands, creating a pattern of attraction and repulsion which attracted a similar pattern but in general repelled a dissimilar pattern. But always the bodies came into contact, and surface tension cannot account for (1)

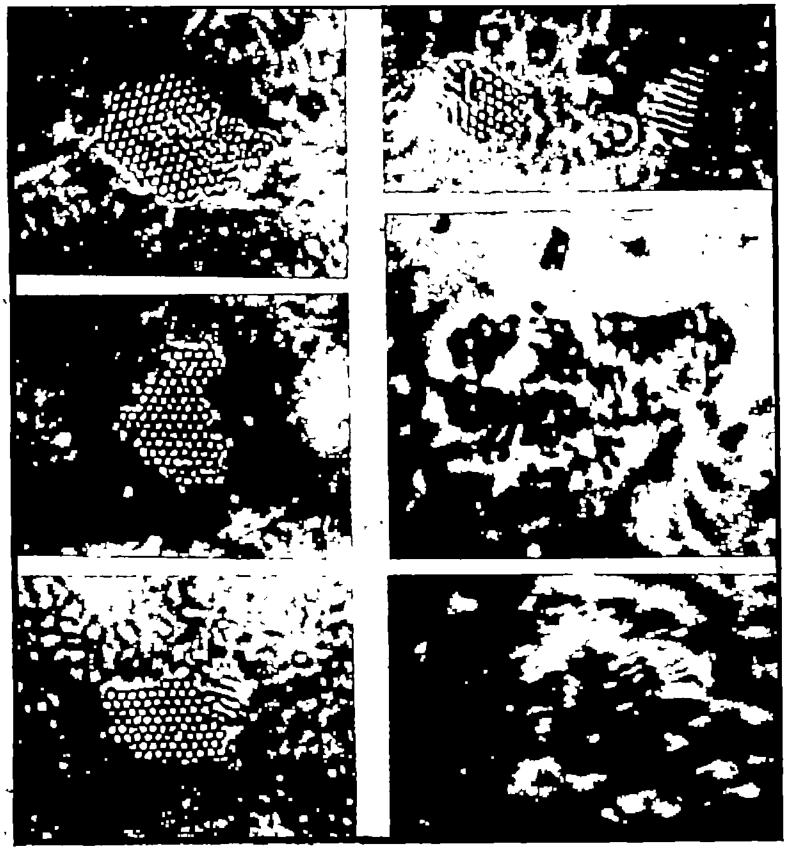

Fig. 1 Three-dimensional bacterial arrays. Left-hand side: end-on view. Right-hand side: side view

the lack of contact of the cells; (2) the fact that some species of bacilli did not orientate parallel (even when alongside others that did), especially if much salt was present (for example, *E. coli* in broth); (3) the occurrence of orientated aggregates in three dimensions, when any forces must act through the medium.

(*b*) *Three-dimensional aggregates.* Attempts to salt-out bacteria with ammonium sulphate (as used by Weibull[10] for bacterial flagellæ) resulted only in disorientated aggregates. Eventually regular three-dimensional aggregates were produced by accident during work on the effect of glycerol on amoebæ. Amoebæ and their associated food organisms were placed in serial dilutions of glycerol in Chalkley's medium in hanging drops, and set aside for a few days. In the range 1·5–3 per cent glycerol, the bacteria were found to have multiplied and in places built up, especially after 2–3 weeks, regular three-dimensional arrays, with the rods arranged parallel and in several layers (see Fig. 1).

All stages were visible, from aggregates of three and four through dozens to hundreds and thousands in dynamic equilibrium with the individual free-swimming ones in the solution. In the same field, the aggregates could be seen end-on (left-hand side of Fig. 1) showing the hexagonal packing of the rods; and sideways on, showing the rows of parallel palisades (right-hand side of Fig. 1); and half end-on, half sideways-on, showing both the ends and the sides of the rods. Focusing up and down showed that the depth of these aggregates was between 10 and 20 μ, corresponding to many layers of cells. The largest aggregate seen was 100 μ long, but it was somewhat twisted, showing that the forces are weak (that is, the crystal is soft). Each crystal had a shimmering or writhing movement, due to thermal agitation of its units or perhaps some residue of suppressed motility. For this reason and owing to the convexity of the sideways-on position, it was difficult to obtain good photographs. By focusing up and down in life the arrangement appears more clearly.

The appearance of the crystals is very similar to electron microscope pictures of virus crystals, for example, tobacco necrosis virus taken by Wyckoff[11], except that the spacing between the bacterial units is about a hundred times greater.

The question arises, should the bacterial arrays be called crystals? This question also arose in connexion with the crystallinity of virus arrays about fifteen years ago. Then Bernal and Fankuchen[8] stated that "crystallinity presupposes an indefinite repetition of identical units in three-dimensional space". The bacterial aggregates fulfil this condition, if one ignores the possible second-order differences within the individual cells. One might add a further stipulation, that the array should result from the mutual attraction of the units, so as to exclude such artificial arrays as pyramids of oranges.

The force required to hold the bacterial arrays together is quite small. A single polypeptide chain has a breaking strength of at least 10^{-4} mgm. weight (calculated from the tensile strength of silk, 30 tons/sq. in.). The weight of a bacterial cell (of volume 1 μ^3) is 10^{-9} mgm., so that a single molecular chain could support the weight of 100,000 bacterial cells, or, allowing for the buoyancy of water, one million bacterial cells. This shows how weak the force between the cells could be compared with a covalent bond.

When subcultures were made from the bacterial arrays in glucose broth, no crystals appeared; but on washing the bacteria and resuspending in 3 per cent glycerol, the crystals formed again. With insufficient washing, three-dimensional spindle-shaped aggregates, up to 100 μ long, containing thousands of approximately parallel cells, were formed on standing.

It is hoped to identify the coliform bacilli which form the arrays and to elucidate those factors in the medium which evoke the force involved. Further details will be published elsewhere.

It seems possible that the forces shown to operate between the bacterial cells may be concerned in various biological processes involving action at a distance of the order of a micron, such as between similar chromosomes at various stages of mitosis and meiosis[12]; between the submicroscopic rod-shaped particles of cellulose which Frey-Wyssling (1952) has shown orientate themselves parallel to one another at the surface of plant cells; between red cells in rouleaux formation; and between orientated fibrils in muscle cells which, when striated, align their bands.

I wish to thank Profs. A. Haddow and J. D. Bernal for their encouragement. This investigation has been supported by grants to the Royal Cancer Hospital and Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. EFFECT OF DEEP AND SHALLOW INCISIONS ON ORGANOGENESIS AT THE FERN APEX

By PROF. C. W. WARDLAW and E. G. CUTTER

Department of Cryptogamic Botany,
University of Manchester

In earlier studies of the apex of *Dryopteris aristata* (*D. austriaca*), it has been shown that if the I_1 position (that is, that of the next leaf primordium to appear), or the last formed primordium, P_1, is isolated from the apical cell group by a deep tangential incision, so that the pre-vascular tissue is severed, a bud is formed; and if I_1, P_1, P_2 or P_3 are isolated from the adjacent older leaf primordia by deep radial incisions, they rapidly increase in size and outgrow older primordia[1,2]. A leaf primordium originates near the base of the apical cone by the enlargement of an elliptical group of superficial meristematic cells and the active division of the small underlying cells. The evidence thus far obtained supports the view that a leaf site is a well-defined locus of accumulation of substances which promote meristematic activity and growth, and that a primordium will be formed when external conditions are suitable and when the regulative effects of the apical cell-group and of the adjacent older primordia admit. The substances determining rapid growth in leaf sites may be accumulated from the adjacent superficial prism-shaped cells or from the underlying pre-vascular tissue.

The histological evidence is indicative of the movement of metabolites between the superficial cells of the apical meristem and the underlying pre-vascular layer. If the latter tissue affords a path for the rapid translocation of nutrients and growth-regulating substances in the apex, it will clearly have a particular importance in morphogenesis. The hypothesis was entertained that the regulative effect of the apical cell group, and of the two adjacent primordia, on the inception and development of a new leaf primordium is exercised by way of the pre-vascular tissue. This hypothesis has been investigated experimentally by comparing the effects on organ formation of various deep and shallow incisions as indicated in Figs. 1 and 2. In the deep incisions, the pre-vascular tissue was completely severed; in the shallow incisions, only the superficial prism-shaped cells were affected, the pre-vascular tissue remaining intact. The exactitude of the surgical operations was verified in appropriate microtome sections of apices.

The following information has been obtained:

(1) When a deep tangential incision is made on the adaxial side of I_1 (or of a young P_1, and sometimes also early-plastochrone P_2 and P_3[2]), a bud and not a leaf is formed; this bud grows rapidly, relative to the adjacent primordia. When the incision is shallow a leaf is formed.

(2) When I_1 (or P_1, P_2, etc.) is isolated by deep radial cuts from the adjacent older leaf primordia, a leaf primordium develops with an accelerated growth-rate and soon outgrows primordia several plastochrones older. With shallow radial cuts, accelerated growth has not been observed.

(3) Deep and shallow cuts abaxial to I_1, P_1, P_2, etc., are apparently not important from the point of view of organogenesis.

(4) When I_1 or P_1 (and sometimes P_2 and P_3) is isolated by four deep cuts, a bud and not a leaf is formed. When the four incisions are shallow, a normally-growing leaf primordium is formed. This latter result relates to the months of active apical growth. In apices which were operated upon during the earlier and later parts of the growing season, however, a very different result was obtained. When the I_1 position was isolated by shallow incisions no primordium appeared; and P_1 and P_2 similarly

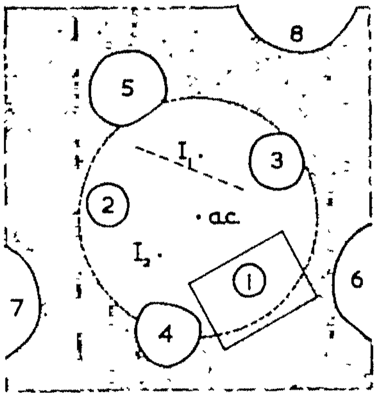

Fig. 1

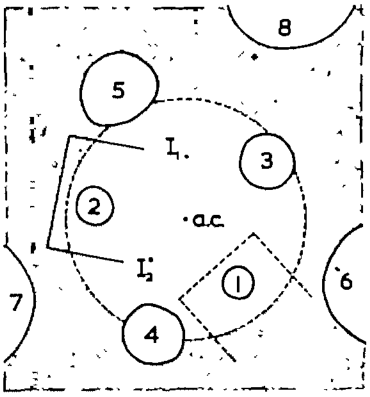

Fig. 2

Fig. 1. Apex of *Dryopteris* as seen from above (diagrammatic). The position of the next primordium to be formed, that is, I_1, has been isolated from the apex by a shallow tangential incision (broken line). Similar deep incisions were also made in other apices. The youngest visible primordium, that is, P_1, has been isolated by four deep incisions (continuous lines), similar shallow incisions being also made in other apices

Fig. 2. Primordium P_1 has been isolated by three shallow incisions, one adaxial, and P_2 by three deep incisions, one abaxial

treated not only failed to grow but gradually disappeared. Primordial growth was, however, usually obtained with a single shallow tangential cut (*see* (1) above).

(5) When early-plastochrone P_1, or P_2, is isolated by four shallow incisions, and the apical cell group of the main axis is punctured, a bud is usually formed.

The hypothesis under consideration, that is, that the regulative action of the apical cell group and adjacent leaf primordia takes place by way of the pre-vascular tissue, is supported by the results obtained. The severance of the pre-vascular tissue leads to important changes in the normal organogenic activity of the apex. Shallow incisions, by contrast, yield no comparable results.

The transformation of an organ of dorsiventral symmetry and ultimately limited growth into one of radial symmetry and potentially unlimited growth, by a simple surgical operation, is of course a remarkable phenomenon for which an explanation must be sought. The suggestion has already been made[1] that the characteristic symmetry and orientation of the leaf, with its limited adaxial growth and extensive tangential and abaxial growth, may be due to the position in which it originates, that is, on the side of the conical apex, together with inhibitional effects proceeding from the apical cell group. The present investigation has shed no new light on this problem; but further experiments directed to this end are in progress. It may here be noted, however, that a deep adaxial incision will not only preclude the basipetal movement of possible growth-inhibiting substances from the apical cell group: it will interfere radically with the whole system of metabolic gradients in the sector of the incision, the more so as a rapid and extensive wound-reaction is a conspicuous feature of injured meristems.

With shallow incisions there was (*a*) a marked wound-reaction and (*b*) the very curious and unexpected disappearance of young primordia at certain times of the year, and the failure of I_1 to appear. It may well be that the latter is directly related to the former, that is, that the rapid formation of wound tissue leads to a dispersal of the substances essential for leaf inception and growth. But since I_1, P_1 or P_2, isolated by deep cuts during the same period, do grow, it may be inferred that the isolated panel has enough of the substance(s) required for organ formation, provided the inhibitive or regulative effects of the apical cell-group and adjacent leaf primordia are eliminated.

The facts that nascent or very young leaf primordia may actually disappear when isolated by shallow incisions, that very young leaf primordia may be induced to develop as buds, and that both leaves and buds may be formed on the same apical meristem when the apical cell has been punctured[3], indicate that the normal fern meristem is a delicately regulated system and that the physiological changes induced in it by some surgical treatment are probably of a radical and far-reaching character.

The investigations briefly outlined here have been carried out in duplicate, that is, by each of the authors using considerable numbers of apices in each experiment and with close observations of each others specimens at critical stages. A fuller account of this work will be given elsewhere. [Sept. 2.

QUALITATIVE ANALYSIS OF ORGANIC COMPOUNDS BY MASS SPECTROMETRY

By J. H. BEYNON

Imperial Chemical Industries, Ltd., Dyestuffs Division,
Hexagon House, Blackley, Manchester 9

IT is well known that mass spectrometers are extensively used for quantitative analysis of mixtures of known components, but it is not so widely realized that they can also be used for qualitative analysis of unknown substances. The purpose of this communication is to direct attention to the potentialities of the mass spectrometer for this purpose and to describe developments which enhance its power. Like other analytical instruments, the mass spectrometer can be used more easily for identifying a pure substance than a mixture; but it has the advantage that it is usually possible from the mass spectrum of an unknown material to determine whether or not it is a mixture. Since the mass spectrometer can handle milligram quantities of material boiling below about 400° C., vapour phase chromatography offers an ideal method for the separation of mixtures into their component parts prior to analysis.

Qualitative analysis by examination of the mass : charge ratios and relative abundances of the various positive ion species formed when a vapour is bombarded with electrons of about 50 eV. energy is based on empirical relationships derived from examination of large numbers of mass spectra; for example, those collected together by the American Petroleum Institute[1]. Terminal groups can often be identified by characteristic peaks; for example, a large peak at mass : charge ratio 30 is strong evidence in favour of an amine or imine. Information as to the general structure of the molecule is also easily obtained. For example, a large 'parent' peak (corresponding to ionization of the whole molecule without fragmentation) indicates a strong structure such as a ring, and the relative abundances of fragment ions usually enable one to decide whether the ring is resonance-stabilized or not. Alkyl side-chains on an aromatic ring tend to break under electron bombardment at the bond next but one to the ring, giving a positive ion containing the ring, whereas a saturated ring tends to break at the bond joining the alkyl group to the ring. Many similar empirical rules can readily be deduced from published mass spectra.

From an analytical point of view, the molecular weight is perhaps the most useful single item of information obtainable by mass spectrometry, and this is determined by mass measurement of the parent peak. If the substance is known to be a hydrocarbon, the molecular weight leads directly to the empirical formula or, in the case of high molecular weights, to a small number of possible empirical formulæ. Thus a molecular weight of 106 gives an empirical formula of C_8H_{10}, and with the aid of rules of breakdown based on comparison spectra it is a simple matter to limit the molecular formula to a small number of possibilities, which can be investigated separately by the use of reference samples, or known chemical or physical properties. If, however, the material is not known to be a hydrocarbon, a much larger number of possible empirical formulæ

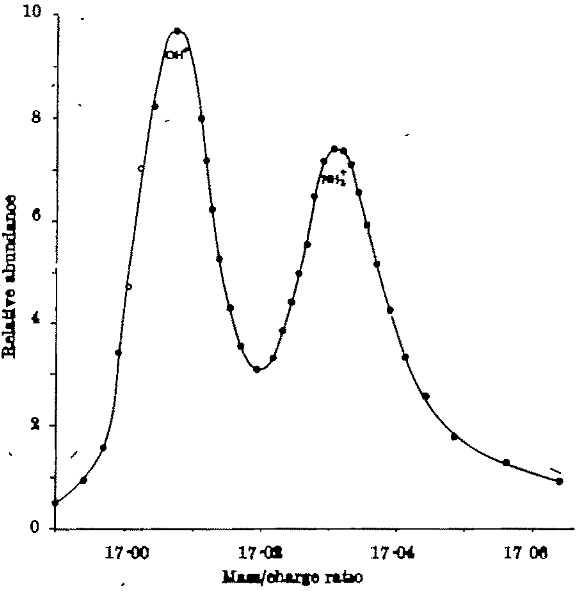

Fig. 1

correspond to a given molecular weight, and often the only useful information to be derived from the molecular weight concerns the number of nitrogen atoms, since all organic compounds of carbon, hydrogen, nitrogen, oxygen, sulphur, phosphorus and the halogens having an odd molecular weight must contain an odd number of nitrogen atoms. Since chlorine and bromine have very abundant isotopes, which are two mass numbers heavier than the main isotopes, the number of chlorine and bromine atoms present in an unknown molecule can usually be determined immediately from the strengths of the isotopic peaks. Numerous atomic arrangements can also be written for all but the lightest fragment ions in the mass spectra of non-hydrocarbon compounds and more than one type of ion may contribute to give a multiple but unresolved mass peak. To overcome the consequent difficulties in interpretation of such mass spectra the technique of accurate mass measurement has been devised.

The principle of this technique is to make use of the fact that atomic masses are not exactly integral multiples of a unit mass. Thus $^{12}CH_2{}^+$ and $^{14}N^+$, both nominally of mass 14, actually have masses of 14·0196 and 14·0070 A.M.U. respectively[3], and so on for more complicated combinations of atoms. It follows that if the mass of any ion is measured with sufficient precision, its elemental composition can immediately be deduced, and the mass spectrum of an unknown substance then gives not only the empirical formula, but also a great deal of information about the arrangement of the atoms within the molecule.

In order to apply the method to multiple mass peaks, a mass spectrometer of high resolving power is necessary, and such an instrument, with a resolving power of 2,500, is being built for this work in these laboratories by Metropolitan-Vickers, Ltd. However, it has been found possible to use an existing Nier type mass spectrometer[4] (90° sector type), with a resolving power of about 250, to prove the validity of the method by narrowing the exit slit. The resolving power attainable is shown in Fig. 1, and although peak heights then no longer give an accurate measure of the abundance of any ion species, this is of no importance during the mass measurements. For reference purposes, a mass spectrum is always plotted with the exit slit opened to its normal width before accurate mass measurements are commenced.

The mass measurements are made by scanning from the unknown mass peak to a reference mass peak of known mass by variation of the accelerating voltage at constant magnetic field. A constant fraction of the accelerating voltage corresponding to each mass is read on a Diesselhorst thermo-electric free potentiometer accurate to 1 part in 10^5. Then $m_1/m_2 = V_2/V_1$. Reference samples giving mass peaks of known composition as close as possible to the unknown mass peak or group of peaks are introduced through a separate sample-handling system to serve as mass standards. Several such samples are necessary for mass measurements on a complete mass spectrum. The principal inaccuracies in the measurements arise from three causes. These are errors due to: (1) neglect of the kinetic energy possessed by the ions on formation; (2) variation of either the magnetic field or accelerating voltage during the measurements; and (3) difficulty in setting on the exact summits of the peaks. The first and only systematic error will be eliminated by the use of double focusing in the new instrument, while the second and third inaccuracies will be very much reduced by more stable circuits and sharper-topped peaks. For the present, the first error is kept as small as possible by working at the highest possible accelerating potential (2,000 volts), and none of the mass peaks so far measured has proved to be in error by more than 1 part in 7,000. Measurements on parent peaks (from parent reference peaks) give results at least three times as accurate as this.

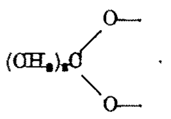
To illustrate the value of the method in deducing the molecular structure from the mass spectrum, accurate mass measurements have been made on the most abundant ionic species in the mass spectrum of α-pyrrolidone. The mass of the parent peak was measured from the parent peak of cyclohexene (82·1040) introduced as a reference, which gave a value of 85·0794. Consideration of the various combinations of carbon, hydrogen, nitrogen and oxygen which can give a nominal molecular weight of 85 then leads directly to the empirical formula. Thus, some of the possibilities are: $C_5H_{11}N^+ = 85·1159$; $C_4H_7NO^+ = 85·0794$; $C_3H_3NO_2{}^+ = 85·0430$; $C_4H_9N_2{}^+ = 85·0907$; $C_3H_5N_2O^+ = 85·0543$. Combinations containing an even number of nitrogen atoms are not included, on account of the odd numbered molecular weight, though their inclusion would lead to no confusion. Lower mass peaks in the spectrum were measured, with the results given in the table.

The fact that the parent peak is the strongest in the spectrum indicates a ring structure; the occurrence of CNO+ ions but not of NO+ ions suggests the presence of a  $-\underset{|}{N}-\overset{O}{\overset{\|}{C}}-$ group, and the ions $C_3H_6N^+$ and $C_3H_6{}^+$ show three adjacent $-CH_2-$ groups. The structure follows immediately.

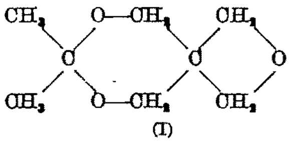
A further advantage of mass measurement appears when the peak of highest mass in the mass spectrum is very weak compared with the next highest peak and, therefore, is easily overlooked. Again, if the strong peak corresponds to an uneven mass, without accurate mass measurement it would be deduced that the compound responsible for it contained an

Reference peak	Nominal mass	Measured masses	Identification
$C_3H_4O^+$ from acetone	56 (triple peak)	56·0323 56·0446 56·0670	$C_2H_2NO^+$ = 56·0310 $C_3H_4O^+$ = 56·0436 $C_3H_6N^+$ = 56·0674
$C_2H_2O^+$ from acetone	42 (quadruple peak)	42·0102 42·0287 42·0538 42·0592	CNO^+ = 42·0109 $C_2H_2O^+$ = 42·0285 $C_2H_4N^+$ = 42·0473 $C_3H_6^+$ = 42·0590
C_2HO^+ from acetone	41 (triple peak)	41·0174 41·0443 41·0503	C_2HO^+ = 41·0158 $C_2H_3N^+$ = 41·0392 $C_3H_5^+$ = 41·0518
O_2^+ from air	30 (triple peak)	30·0169 30·0438 30·0533	CH_2O^+ = 30·0196 CH_4N^+ = 30·0435 $C_2H_6^+$ = 30·0561
CH_4N^+ from unknown	28 (triple peak)	28·0117 28·0268 28·0365	$CO^+ + N_2^+$ (from air) unresolved CH_2N^+ = 28·0272 $C_2H_4^+$ = 28·0398
CH_2N^+ from unknown	27 (double peak)	27·0184 27·0322	CHN^+ = 27·0190 $C_2H_3^+$ = 27·0316

odd number of nitrogen atoms. An example of this is provided by the mass spectrum of 6 : 6-dimethyl-1 : 5 : 7-trioxa-3 : 5-spirononane (I), which was selected as a test of the method. The first strong peak (143) is more than 3,000 times stronger than the parent peak (158), which might easily have been attributed to an impurity. Careful mass measurements on this and other strong mass peaks proved that the compound contained no nitrogen, but three atoms of oxygen. The empirical formula for ions of mass 143 was $C_7H_{11}O_3^+$ and the formula for the complete molecule was assumed to be $C_8H_{14}O_3$, since a prominent peak at mass 15 proved to be CH_3^+. Other peaks at 113 and 86 respectively proved to be $C_6H_9O_2^+$ and $C_5H_{10}O^+$ and clearly represent entirely different modes of fracture of the molecule. Assuming the molecule to be of the form $X + Y + Z$, the two peaks being $X + Y$ and $Y + Z$ respectively, we have $X = C_3H_4O_2$, $Y = C_3H_5$, $Z = C_2H_5O$ giving the dispositions of the carbons and oxygens. Too much reliance is not placed on the hydrogens due to the ease with which they take part in re-arrangements on ionization. A very strong peak at 41 ($C_3H_5^+$) could not have come from the centre of the molecule, so that the molecule is probably ($C_3H_?$) (O_2) ($C_3H_?$) ($C_2H_?O$). A knowledge of the chemistry involved, together with an infra-red spectrum, would usually enable the final step to the complete structure to be taken, while the empirical rules of breakdown referred to at the beginning of this communication suggest the group :

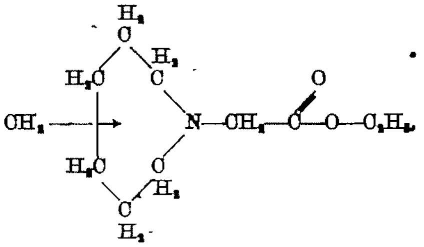


by analogy with similar compounds (for example, 2-methyl-1 : 3-dioxalane) which give very weak parent peaks. In this case the formula is :

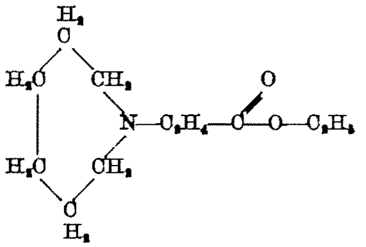


(I)

The compound of unknown constitution of highest molecular weight so far examined by this method was of molecular weight 199. Its structure was deduced by accurate mass measurements alone to be :



the arrow indicating that the position of the CH_3 group on the ring is uncertain. The actual structure was :



Our experience during the past three months has shown the above technique, either alone or in conjunction with infra-red spectroscopy, to be of wide application in the identification of small quantities of unknown organic compounds.

TOXIC FLUORINE COMPOUNDS

By Dr. F. L. M. PATTISON

Department of Chemistry, University of Western Ontario, London, Canada

IN an earlier report[1] we have described the preparation and toxicities of several series of aliphatic compounds containing an ω-fluorine atom ; these included ω-fluorocarboxylates, ω-fluoroalcohols, ω-fluoroaldehydes, ω-fluoronitriles, ω-fluoroamines and ω-fluoro-ω′-nitroalkanes. An attempt was made to correlate the toxicities with known metabolic mechanisms ; in general, it was apparent that those compounds which could give rise *in vivo* to an ω-fluorocarboxylic acid containing an even number of carbon atoms were toxic, whereas all others were innocuous. The present communication gives a further account of the preparation and toxicity of allied compounds. Standard comparison figures and procedures for testing are the same as those described in the earlier report. To avoid ambiguity, fluorine is not generally referred to as a halogen throughout this report.

ω-Fluoroalkyl halides, $F(CH_2)_nX$. Several of the lower members of this series ($n = 2$–5) have already been described[2–4] ; of the preparations reported, the most satisfactory general method involves the partial fluorination of ω,ω′-dihalogenoalkanes using potassium fluoride in diethylene glycol[5].

We have obtained ω-fluoroalkyl halides by the following general routes :

$$(1)\ F(CH_2)_nOH \xrightarrow[\text{or } SOCl_2]{PBr_3} F(CH_2)_nX\ ;$$

$$(2)\ X(CH_2)_nX \xrightarrow{KF} F(CH_2)_nX\ ;$$

$$(3)\ F(CH_2)_nO.SO_2R + KX \rightarrow F(CH_2)_nX + KO.SO_2R\ (R = CH_3{}^- \text{ or } p\text{-}CH_3.C_6H_4{}^-)\ ;$$

$$(4)\ X(CH_2)_nO.SO_2R + KF \rightarrow X(CH_2)_nF + KO.SO_2R\ (R = CH_3{}^- \text{ or } p\text{-}CH_3.C_6H_4{}^-).$$

ω-Fluoroalkyl iodides are most readily prepared by method (3), or by treatment of the corresponding ω-fluoroalkyl chlorides with potassium iodide in acetone; methods (1) and (2) are most convenient for preparing the chlorides and bromides. A fifth general method is mentioned below, under 'anodic syntheses'.

The value of these derivatives lies in the greater stability of the carbon–fluorine bond relative to that of the other carbon–halogen bonds, making it possible to replace the halogen atom by standard reactions without affecting the fluorine atom. They have thus become valuable synthetic intermediates, and from them we have prepared ω-fluoroalkynes, ω-fluoroethers, ω-fluoronitriles, ω-fluoro-ω′-nitroalkanes, ω-fluorothiocyanates and other miscellaneous ω-fluorocompounds. Further reference to their importance in synthetic work will be made below, in connexion with Grignard reactions.

Very few references to the pharmacology of aliphatic monohalogen compounds are available. Ethyl chloride apparently does not form ethyl alcohol when used as a general anæsthetic, and ethyl iodide is very largely recovered unchanged in the urine and respiratory gases when used for testing circulatory rates[4]. If one applies these observations to the 2-fluoroethyl halides, it follows that they would not give rise to fluoroethanol and hence would not be toxic; this conclusion has already been confirmed by previous workers[5] in the case of 2-fluoroethyl chloride and 2-fluoroethyl bromide. In spite of this, we thought that certain representative higher members should be examined because of their more labile halogen, and hence more ready conversion to the corresponding fluoroalcohol. Some results are shown in Table 1.

Table 1

Compound	Formula	L.D. 50 for mice (mgm./kgm.)
2-Fluoroethyl iodide	$F(CH_2)_2I$	23
3-Fluoropropyl bromide	$F(CH_2)_3Br$	> 100
4-Fluorobutyl chloride	$F(CH_2)_4Cl$	1·25
4-Fluorobutyl bromide	$F(CH_2)_4Br$	8·2
4-Fluorobutyl iodide	$F(CH_2)_4I$	5·2
5-Fluoroamyl chloride	$F(CH_2)_5Cl$	32
6-Fluorohexyl chloride	$F(CH_2)_6Cl$	5·8
6-Fluorohexyl bromide	$F(CH_2)_6Br$	12·8
7-Fluoroheptyl chloride	$F(CH_2)_7Cl$	> 100
8-Fluorooctyl chloride	$F(CH_2)_8Cl$	2·3
8-Fluorooctyl bromide	$F(CH_2)_8Br$	20
9-Fluorononyl chloride	$F(CH_2)_9Cl$	> 100
10-Fluorodecyl chloride	$F(CH_2)_{10}Cl$	5·0
11-Fluoroundecyl bromide	$F(CH_2)_{11}Br$	> 100
12-Fluorododecyl bromide	$F(CH_2)_{12}Br$	16

From these figures, it is apparent that the even members are of the same order of toxicity as the corresponding members of the original ω-fluorocarboxylate series. This in turn is good evidence of the ready loss of the halogen in all but the lowest members of the series.

Because of the resistance of the carbon–fluorine bond to hydrolysis, it was expected that the ω,ω′-*difluoroalkanes*, $F(CH_2)_nF$, would be excreted unchanged. Three members were submitted for routine testing and, surprisingly, were found to be moderately toxic. No alternation was apparent on the basis of the L.D. 50 figures: 1,4-difluorobutane ($n = 4$), 19·5 mgm./kgm.; 1,5-difluoropentane ($n = 5$), 12 mgm./kgm.; and 1,18-difluorooctadecane ($n = 18$), 10 mgm./kgm.

ω-*Fluoroalkenes* $F(CH_2)_nCH{=}CH_2$, *and* ω-*Fluoroalkynes*, $F(CH_2)_nC{\equiv}CH$. ω-*Fluoroalkenes* have not been studied extensively hitherto; the only member that we have prepared so far[1] is 11-fluoro-undec-1-ene, $F(CH_2)_9CH{=}CH_2$, which has an L.D. 50 of 9·3 mgm./kgm. It is thus considerably more toxic than 11-fluoroundecanol, 11-fluoroundecyl bromide or ethyl 11-fluoroundecanoate, all of which have an L.D. 50 greater than 100 mgm./kgm., but less toxic than 11-fluoro-1,2-dihydroxyundecane, $F(CH_2)_9CH(OH).CH_2OH$ (L.D. 50, 1·75 mgm./kgm.). It is suggested that some hydroxylation of the double bond occurs *in vivo* giving the dihydroxy-derivative, which is afterwards converted to the toxic 10-fluorodecanal:

$$F(CH_2)_9CH{=}CH_2 \rightarrow F(CH_2)_9CH(OH).CH_2OH \rightarrow F(CH_2)_9CHO.$$

ω-*Fluoroalkynes* can readily be prepared from ω-fluoroalkyl halides by reaction with sodium acetylide in liquid ammonia[6] or from the corresponding ω-chloroalkynes by fluorination with potassium fluoride:

$$F(CH_2)_nX + NaC{\equiv}CH \rightarrow F(CH_2)_nC{\equiv}CH + NaX$$
$$Cl(CH_2)_nC{\equiv}CH + KF \rightarrow F(CH_2)_nC{\equiv}CH + KCl.$$

They form solid metallic derivatives, for example, *bis*-6-fluorohex-1-ynyl mercury, $F(CH_2)_4C{\equiv}C.Hg.C{\equiv}C(CH_2)_4F$; but so far we have been unsuccessful in replacing the acetylenic hydrogen with organic groupings. Because the extreme electronegativity of fluorine leads to a highly polar carbon–fluorine bond, the ω-fluoroalkynes tend to lose fluorine in the presence of reagents such as sodamide and Grignard reagents, rather than undergo the reactions characteristic of the non-fluorinated alkynes. Thus, the reaction of 6-fluorohex-1-yne with sodamide produced an indeterminate mixture of products, and with ethyl magnesium bromide followed by carbon dioxide produced fluorine-free polymers.

It can be seen from Table 2 that the ω-fluorine atom confers toxic properties on the acetylenes.

ω-*Fluoroalkyl thiocyanates*, $F(CH_2)_nSCN$. These compounds were prepared in an attempt to combine the toxic action of the thiocyanate grouping with that of the ω-fluoroalkyl grouping. Two lower members had already been prepared, namely, 2-fluoroethyl thiocyanate[6], $F(CH_2)_2SCN$, and 3-fluoropropyl thiocyanate[7], $F(CH_2)_3SCN$. Since the toxicities of these two members differed only slightly, it was considered likely that the toxicity was associated exclusively with the thiocyanate grouping. To con-

Table 2

n-Amyl thiocyanate	$CH_3(CH_2)_4SCN$	75
2-Fluoroethyl thiocyanate	$F(CH_2)_2SCN$	15
3-Fluoropropyl thiocyanate	$F(CH_2)_3SCN$	18
4-Fluorobutyl thiocyanate	$F(CH_2)_4SCN$	2·6
5-Fluoroamyl thiocyanate	$F(CH_2)_5SCN$	30
6-Fluorohexyl thiocyanate	$F(CH_2)_6SCN$	5·0

firm this, three adjacent higher members, together with a non-fluorinated member, were prepared[8] from the corresponding halogen compounds by reaction with potassium thiocyanate. Results are shown in Table 3.

It can be seen that, contrary to expectation, the fluorine is essential for high toxicity, and that the even-membered derivatives are again the more toxic. It seemed possible that the thiocyanates were being reduced *in vivo* to hydrogen cyanide and the corresponding mercaptan:

$$F(CH_2)_nSCN + 2H \xrightarrow{\text{hydrogenase}} F(CH_2)_nSH + HCN.$$

This line of reasoning led us to investigate the ω-fluoroalkyl mercaptans, the high toxicity of which added weight to the suggestion.

ω-Fluoroalkyl mercaptans, $F(CH_2)_nSH$. As mentioned in the preceding section, mercaptans were prepared for comparison with the thiocyanates; they are also of interest as the sulphur analogues of the ω-fluoroalcohols. In the initial experiments, the preparation of the ω-fluoroalkyl mercaptans proved to be difficult. The standard reactions, such as interaction of the corresponding bromide with thiourea followed by hydrolysis, gave very low yields. Moreover, the members containing four, five and six carbon atoms tended to cyclize very readily, forming tetrahydrothiophene, tetrahydrothiopyran and hexamethylene sulphide, respectively. From a consideration of the behaviour of the thiocyanates, we decided to simulate the suggested biological reduction by treatment with lithium aluminium hydride. The ω-fluoroalkyl mercaptans were thus obtained[9–10] in 80 per cent yield. The only exception was 4-fluorobutyl mercaptan, which still cyclized to tetrahydrothiophene; accordingly, its acetate, 4-fluorobutyl thiolacetate, was synthesized[10] directly by the following steps:

$$F(CH_2)_4I + AgO.SO_2C_6H_4.CH_3 \rightarrow F(CH_2)_4O.SO_2C_6H_4.CH_3;$$
$$F(CH_2)_4O.SO_2C_6H_4.CH_3 + KSAc \rightarrow F(CH_2)_4SAc + KO.SO_2C_6H_4.CH_3.$$

We had previously shown this method to be satisfactory for the preparation of 2-fluoroethyl thiolacetate.

As can be seen from Table 4, a pronounced alternation is again apparent, with toxicities comparable to those of the ω-fluoroalcohol series. It is possible that those mercaptans with an even number of carbon atoms are toxic due to biological conversion to the corresponding ω-fluoroalcohols by transthiolation $[F(CH_2)_nSH \rightarrow F(CH_2)_nOH]$.

Table 4

Compound	Formula	L.D. 50 for mice (mgm./kgm.)
n-Amyl mercaptan	$CH_3(CH_2)_4SH$	>100
2-Fluoroethyl thiolacetate	$F(CH_2)_2SAc$	56
3-Fluoropropyl mercaptan	$F(CH_2)_3SH$	>100
4-Fluorobutyl thiolacetate	$F(CH_2)_4SAc$	1·8
5-Fluoroamyl mercaptan	$F(CH_2)_5SH$	>100
6-Fluorohexyl mercaptan	$F(CH_2)_6SH$	1·25

ω-Fluoroalkanesulphonyl chlorides and fluorides, $F(CH_2)_nSO_2X$. The ω-fluoroalkanesulphonic acids, $F(CH_2)_nSO_3H$, are the sulphonic acid analogues of the ω-fluorocarboxylate series, $F(CH_2)_nCOOH$, and the two classes thus bear a superficial resemblance to one another. In order to compare the effects of the two classes, representative derivatives of the former were prepared and tested. It has been reported that *n*-alkanesulphonic acids are non-toxic[11] and are excreted unchanged by the dog[12]; hence no great activity was anticipated for the ω-fluoro-derivatives. Two members of the sulphonyl chloride series had been prepared previously, 2-fluoroethanesulphonyl chloride[6], $F(CH_2)_2SO_2Cl$, and 3-fluoropropanesulphonyl chloride[7], $F(CH_2)_3SO_2Cl$; but toxicity determinations on these derivatives were indefinite. We prepared[10,13] the members listed in Table 5 by two general routes:

$$(1)\ F(CH_2)_nX \xrightarrow{\text{KCNS}} F(CH_2)_nSCN \xrightarrow{\text{Cl}_2\text{ aq.}} F(CH_2)_nSO_2Cl \xrightarrow{\text{KFHF}} F(CH_2)_nSO_2F;$$

$$(2)\ F(CH_2)_nOH \xrightarrow{\text{TsCl}} F(CH_2)_nOTs + S{=}C(NH_2)_2 \rightarrow [F(CH_2)_nS.C(NH_2) = NH_2]^{+}{}^{-}OTs$$
$$(Ts = p\text{-}CH_3.C_6H_4SO_2—)$$
$$\xrightarrow{\text{Cl}_2\text{ aq.}} F(CH_2)_nSO_2Cl \xrightarrow{\text{KFHF}} F(CH_2)_nSO_2F.$$

From an examination of the toxicity results so far available, it can be seen that the sulphonyl chlorides exhibit a definite alternation in toxicity. This suggests that β-oxidation of the sulphonyl chlorides may occur, a point which is being investigated further by the preparation and study of related compounds. On the other hand, little or no correlation between structure and toxicity is apparent in the case of the sulphonyl fluorides; such activity as they possess may be connected with cholinesterase inhibition[14].

Table 5

Value of *n* in $F(CH_2)_nSO_2X$	L.D. 50 for mice (mgm./kgm.)	
	X = Cl	*X* = F
2	< 10	—
3	64	84
4	18	10
5	> 100	88
6	9	45
$CH_3(CH_2)_5SO_2X$	> 100	70

Miscellaneous ω-fluoro sulphur compounds. Methyl and ethyl fluorothiolacetate, $FCH_2CO.SR$ ($R = CH_3—$ and $C_2H_5—$), were prepared for enzyme studies. Both had a toxicity very similar to that of methyl fluoroacetate. This is readily explained by hydrolysis *in vivo* to the toxic fluoroacetate ion.

ω-Fluoroalkyl methanesulphonates, benzenesulphonates and *p*-toluenesulphonates were prepared as intermediates for other syntheses. Three general methods of preparation were used:

$$(1)\ F(CH_2)_nOH + ClSO_2R \rightarrow F(CH_2)_nO.SO_2R + HCl \quad (R = CH_3—,\ C_6H_5—,\ p\text{-}CH_3.C_6H_4—)$$

$$(2)\ F(CH_2)_nOH + FSO_2R \rightarrow F(CH_2)_nO.SO_2R + HF \quad (R = CH_3—,\ p\text{-}CH_3.C_6H_4—);$$

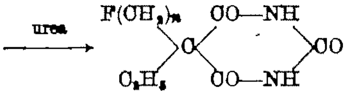
$$(3)\ F(CH_2)_nX + AgO.SO_2R \rightarrow F(CH_2)_nO.SO_2R + AgX \quad (R = CH_3—,\ p\text{-}CH_3.C_6H_4—).$$

It is of interest that both 2-fluoroethyl and 3-fluoropropyl methanesulphonate were non-toxic (L.D. 50, > 100 mgm./kgm.); since the two parent fluoro-alcohols show a marked difference of toxicity, the conclusion may be drawn that at least the 2-fluoroethyl derivative is not readily hydrolysed *in vivo*. On the other hand, the fact that 4-fluorobutyl methanesulphonate had an L.D. 50 of 1 mgm./kgm. suggests that hydrolysis of this member is occurring, giving rise to the toxic 4-fluorobutanol.

Compounds of Biological Interest

Two *fluorinated barbiturates*, 5-ethyl-5-(4′-fluorobutyl)-barbituric acid (fluoroneonal) and 5-ethyl-5-(5′-fluoroamyl)-barbituric acid, have been prepared[14] for comparison with the non-fluorinated materials. Their synthesis was carried out as follows:

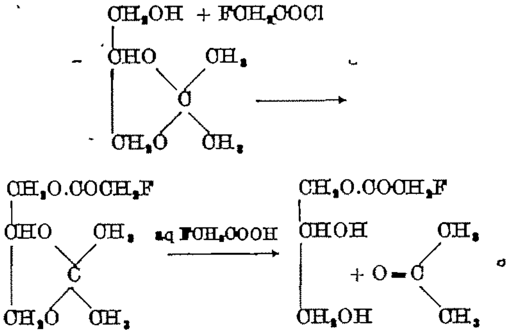
$$F(CH_2)_nX + NaCEt.(COOEt)_2 \rightarrow F(CH_2)_nCEt.(COOEt)_2$$



(n = 4 and 5; X = Br or I).

Their activity as central nervous depressants was considerably less than that of their non-fluorinated analogues and their toxicity was relatively low. These conclusions have been confirmed recently by Bruce and Huber[15], who prepared various 5-(3′-fluoropropyl)- and 5-(5′-fluoroamyl)-barbituric acids; they concluded that the products were less effective than the non-fluorinated analogues. The intermediate fluoro-esters obtained in our syntheses were non-toxic.

Chenoweth has reported[16] that glyceryl 1-monoacetate (monoacetin) is effective in offsetting the symptoms of fluoroacetate poisoning. If a reason for this therapy is the liberation of a particularly active 'C_2 fragment' for competition with fluoroacetate, then it follows that *glyceryl 1-monofluoroacetate* (fluoromonoacetin) might give rise to a particularly active 'fluoro-C_2 fragment', with resultant enhancement of toxicity or speed of action. This was prepared by an unequivocal route, and was found to be neither more toxic (L.D. 50 for mice, 12 mgm./kgm.) nor faster acting than methyl fluoroacetate.



Glyceryl tris-monofluoroacetate (fluorotriacetin), prepared for comparison with fluoromonoacetin, was found to be rather more toxic (L.D. 50 for mice, 6·7 mgm./kgm.) but otherwise did not differ in its effects.

For comparison with oxalacetic acid, *diethyl fluoro-oxalacetate*, $C_2H_5OOC.CHF.CO.COOC_2H_5$, was prepared[10] by a Claisen condensation of ethyl fluoroacetate and diethyl oxalate; it was found to be non-toxic (L.D. 50, > 400 mgm./kgm.).

Fluorinated esters and ethers are being screened for insecticidal properties. The following compounds have already been tested: fluoroethyl valerate, caproate, caprylate, pelargonate, caprate, laurate, tridecanoate, myristate, palmitate, stearate, oleate and benzoate; octyl, decyl, undecyl, dodecyl, tetradecyl, hexadecyl, octadecyl, undecylenyl and phenyl fluoroacetates; methyl 5-fluoroamyl ether, methyl 6-fluorohexyl ether, 1,2,2,2-tetrachloroethyl 2′-fluoroethyl ether and 2-fluoroethyl 2′-butoxyethyl ether.

Work is proceeding on the synthesis of fluorinated analogues of other drugs and metabolites; these are being examined for activity in the treatment of specific diseases. Other compounds are being prepared in which the fluorine will be used as a 'tag' in biochemical and pharmacological studies. Full details of these phases of this work will be reported at a later date.

Preparation of Monofluoro Compounds

A survey of the literature has shown that general methods of preparation of monofluorinated organic compounds have never been the object of an extensive investigation. This problem is now under review with special emphasis on metal fluorides, solvents, type of halogen, temperature and other reaction conditions.

At the present time the introduction of the fluorine atom is most readily carried out by the reaction of potassium fluoride with the corresponding halogen compound. The technique for this reaction is dependent on the stability and on the quantity of the material to be fluorinated. In general, the most satisfactory method involves heating with excess potassium fluoride in ethylene glycol or diethylene glycol with vigorous stirring[3,17,18]; acetamide has recently been reported as an alternative solvent for the reaction[19]. The product can be continuously distilled from the reaction mixture, or the heating may be carried out under reflux with subsequent isolation of the product. By modifications of temperature and concentrations, yields of 40–70 per cent are obtained. If the product or reactants are unstable in hydroxylic solvents, the reaction may be carried out in a stainless steel autoclave under anhydrous conditions using vigorous stirring and no solvent; however, only a limited number of compounds can be fluorinated satisfactorily by this method, and the large volume of our reaction bomb makes it useless for small-scale exploratory runs, particularly those involving expensive or rare intermediates.

When halogen exchange was not practicable, we have prepared[10] monofluoro compounds from alkyl sulphonates by treatment with potassium fluoride according to methods of earlier workers[4,20]. The alkyl sulphonates were originally prepared from the corresponding alcohols by reaction with sulphonyl chlorides in the presence of pyridine or sodium hydroxide:

$$R.OH + ClSO_2R' \rightarrow R.SO_2R' + HCl;$$

$$RO.SO_2R' + KF \rightarrow RF + KO.SO_2R'$$

(R', aliphatic or aromatic).

For satisfactory yields in the potassium fluoride cleavage, it is advantageous to exclude all traces of sulphonyl chlorides and ionic chloride. Consequently, we developed a modified preparation of the alkyl sulphonates to avoid these impurities: this involves treatment of an alcohol with a sulphonyl fluoride, in the presence of excess anhydrous potassium fluoride to remove the resultant hydrogen fluoride as potassium bifluoride. Excellent yields (90–95 per cent) of alkyl sulphonates were thus obtained. The advantages of carrying out the sulphonation and fluorination as a one-step process are being investigated.

We have made use of anhydrous hydrogen fluoride to a limited extent in a variety of reactions such as addition to unsaturated compounds and opening of cyclic ethers. In certain specific reactions, different metal fluorides have been employed; of these, silver fluoride is particularly useful for small-scale trial fluorinations of relatively stable halogen compounds. Zinc fluoride is convenient for forming acyl fluorides. The use of potassium bifluoride for forming sulphonyl fluorides has been mentioned earlier in this article.

The carbon–fluorine bond is stable to most reagents. Thus the functional groups of ω-fluoro compounds undergo a wide variety of reactions, such as replacements, oxidations and reductions, without simultaneous loss of fluorine. Many of these have been mentioned throughout these reports, but two general synthetic routes are worthy of comment here:

(*a*) *Grignard reactions.* The potentialities of ω-fluoroalkyl Grignard reagents, $F(CH_2)_nMgX$, are great, since they offer a simple and direct route to a large number of complex and otherwise inaccessible ω-fluoro compounds. Hoffmann[3] reported that although the ω-fluoroalkyl bromides appeared to react normally with magnesium and dry ether, the only products obtained were devoid of fluorine. Accordingly, it was postulated that transitory formation of the Grignard reagent resulted in preferential loss of magnesium fluoride. More recently, we reported[6] preliminary experiments using 11-fluoroundecyl bromide in which normal Grignard formation and reactions appeared to occur. We have now re-examined this problem, and have proved that, by very careful control of the initiation of Grignard formation and of conditions for subsequent replacements, the normal reactions can be made to take place[10]; for example:

$$F(CH_2)_6X \rightarrow F(CH_2)_6MgX \xrightarrow[-80°\,C.]{CO_2} F(CH_2)_6CO.OMgX \xrightarrow{hydr.}$$

$$F(CH_2)_6COOH \text{ (64 per cent overall yield).}$$

A systematic study is being undertaken to determine the effect of different chain-lengths, of different halogens, of different metals, of variations in conditions and of different types of Grignard reactions.

(*b*) *Anodic syntheses.* Except for one very recent reference[21], no mention appears in the literature of the Kolbe electrolytic coupling with any type of halogen-containing acid, other than halogenated acetic acids. As a preliminary study, we have developed[10] a route to ω,ω′-dihalides from ω-halogenoacids (*c.* 50 per cent yield). Thus 3-chloropropionic acid forms 1,4-dichlorobutane and 5-chlorovaleric acid forms 1,8-dichlorooctane:

$$2\ Cl(CH_2)_nCOOH \rightarrow Cl(CH_2)_{2n}Cl + 2\ CO_2 + H_2.$$

The dihalides on partial fluorination yield the corresponding ω-fluoroalkyl halides.

ω-Fluoroacids undergo this same type of reaction; for example, 10-fluorodecanoic acid forms 1,18-difluorooctadecane (69 per cent yield). We have now applied the method to mixed couplings of the following types:

$$F(CH_2)_nCOOH + HOOC(CH_2)_mCOOR \rightarrow F(CH_2)_{n+m}COOR + 2\ CO_2 + H_2;$$

$$F(CH_2)_nCOOH + HOOC(CH_2)_mCl \rightarrow F(CH_2)_{n+m}Cl + 2\ CO_2 + H_2.$$

Thus, 10-fluorodecanoic acid with methyl hydrogen sebacate forms methyl 18-fluorostearate, and with 5-chlorovaleric acid forms 13-fluorotridecyl chloride.

Summary. Representative members of various chemical species containing an ω-fluorine atom have been prepared and tested on mice by subcutaneous injection; chemical classes described in this article include ω-fluoroalkyl halides, ω-fluoroalkenes and ω-fluoroalkynes, ω-fluoroalkyl thiocyanates, ω-fluoroalkyl mercaptans, ω-fluoroalkanesulphonyl chlorides and fluorides, miscellaneous ω-fluoro sulphur compounds, and certain fluorinated analogues of significant pharmacological compounds. An attempt has been made to correlate the toxicities with known metabolic mechanisms: the results and conclusions exemplify a simple and clear-cut method of demonstrating *in vivo* conversions of certain functional groups in aliphatic compounds. The preparation and synthetic uses of these fluorine compounds have been surveyed briefly. Full details of preparation, physical constants and analytical data, together with a more complete bibliography, will be presented in the appropriate journals in due course.

We are indebted to the Defence Research Board of Canada for funds to provide salaries, chemicals and apparatus (Contract DRB *X*-24) and for permission to publish this work (DRB Report No. SW-1). We are very grateful to Drs. M. K. McPhail and F. C. G. Hoskin and Mr. P. A. Adie, Suffield Experimental Station, Ralston, Alberta, for carrying out the toxicity determinations, and to Dr. F. E. Shideman, University of Wisconsin, for testing the fluorobarbiturates as central nervous depressants. The following have collaborated in this work: G. M. Brown, R. R. Fraser, W. C. Howell, W. C. McMurray, J. E. Millington, J. J. Norman, J. B. Stothers and R. W. White. [May 3.

Growth-regulating Activity of Certain 2 : 6-Substituted Phenoxyacetic Acids

In recent studies[1–4] of the mechanism of action of plant growth-regulating compounds it has been postulated that active phenoxyacetic acids become attached at two points to a specific substrate within the cell, the points of attachment being the carboxyl group and a position in the ring *ortho* to the side-chain. So far, phenoxyacetic acids substituted in the 2- and 6-ring positions have not been regarded as active in the *Avena* straight-growth test. On the basis of other tests it has been put forward that high activity in chlorophenoxyacetic acids is associated with the presence of two unsubstituted positions in the ring *para* to each other. It has also been claimed that 2 : 6-dichlorophenoxyacetic acid and 2 : 4 : 6-trichlorophenoxyacetic acid are not themselves active but behave as anti-auxins. That is, when these compounds are mixed with either indolylacetic acid or 2 : 4-dichlorophenoxyacetic acid the resulting stimulation in extension growth of *Avena* coleoptiles is less than that induced by indolylacetic acid or 2 : 4-dichlorophenoxyacetic acid alone. Evidence of this type has led to the proposal that 2 : 6-substituted compounds have only a single point of attachment to the substrate and act as anti-auxins by blocking one of the two-point attachments of other more active compounds. From experiments carried out in this Department, however, it is now clear that the interpretation of the above results requires further consideration.

Table 1. Activity of some 2 : 6-Substituted Phenoxy Acids in the Went Pea Curvature Test and *Avena* Extension Growth Test. Measurements after 24 Hours

Compound	Split pea stems		*Avena* coleoptiles	
	Optimum conc. (molar)	Max. degree curvature	Optimum conc. (molar)	Max. ext. growth % of control
2 : 4-Dichlorophenoxy-acetic acid	5×10^{-6}	304	5×10^{-6}	140
2 : 6-Dichlorophenoxy-acetic acid	$1·25 \times 10^{-4}$	228	—	—*
,, -propionic acid	$2·5 \times 10^{-5}$	286	10^{-4}	60
,, -butyric acid	5×10^{-5}	210	$2·5 \times 10^{-4}$	60
2 : 6-Dimethylphenoxy-acetic acid	6×10^{-4}	43	—	—*
,, -propionic acid	$2·5 \times 10^{-4}$	146	$7·5 \times 10^{-4}$	24
,, -butyric acid	5×10^{-5}	211	$2·5 \times 10^{-4}$	24
,, -valeric acid	5×10^{-5}	114	—	—*
2 : 4 : 6-Trichlorophenoxy-acetic acid	$2·5 \times 10^{-4}$	73	—	—*
-propionic acid	$2·5 \times 10^{-5}$	117	—	—*
2-Methyl-4 : 6-dichlorophenoxy-acetic acid	$1·5 \times 10^{-4}$	67	—	—*
,, -propionic acid	$2·5 \times 10^{-5}$	153	—	—*

* No statistically significant increase in extension growth

A series of 2 : 6-substituted phenoxyacetic acids with alkyl substitutions in the side-chain was synthesized and tested over a wide concentration-range in the Went pea curvature and *Avena* straight-growth tests. The results for curvature and extension growth after the conventional period of twenty-four hours are given in Table 1.

All the compounds induced curvature in the pea test and in every case substitution of methyl or ethyl groups in the side-chain resulted in an increase in activity. Only the α-methyl and α-ethyl substituted acetic acids of the 2 : 6-dichloro- and 2 : 6-dimethyl-phenoxy acids induced a statistically significant increase in straight growth in the *Avena* test. The fact that activity can be obtained when electropositive (chlorine) or electronegative (methyl) substituents are present in the ring is not in accord with previous electronic considerations of growth-regulating activity.

On the basis of the data recorded at the end of twenty-four hours none of the acetic acids which were unsubstituted in the side-chain induced extension growth of the *Avena* coleoptile. However, when measurements are made at intervals of 2, 4, 6, 9, 12 and 24 hr. different conclusions are reached. At a concentration of 125 p.p.m. of the 2 : 6-dichlorophenoxyacetic acid, extension growth was increased over that of the controls by 39 and 21 per cent at the end of 4 and 6 hours respectively, followed by growth inhibition at 9, 12 and 24 hours. On the other hand, no positive response was obtained with the 2 : 6-dimethyl-, 2 : 4 : 6-trichloro- or 2-methyl-4 : 6-dichlorophenoxyacetic acids.

Experiments carried out with segments of pea internodes have shown that extension growth is directly proportional to water uptake[5]. Using the latter as a measure of growth, it was found that 2 : 6-dimethylphenoxyacetic acid between 200 and 1,000 p.p.m. brought about a statistically significant increase in water uptake over that of controls after 4 and 6 hours, whereas no increase was apparent in measurements made at other time-intervals up to 24 hours.

When measured droplets of any of these compounds were applied to the adaxial surface of the first pair of leaves of four-leaf sunflower seedlings, it was found that concentrations more than two hundred times that of 2 : 4-dichlorophenoxyacetic acid were required to give a similar growth response. Such differences suggest that although these compounds are active when they have reached the site of action, they may penetrate slowly or are not readily translocated.

It would seem clear, therefore, that 2 : 6-substituted phenoxyacetic acids can no longer be simply classified as inactive compounds or as anti-auxins.

Further details of this work are being published elsewhere.

Stimulation of the Discharge of Gametangia from a Brown Alga by a Change from Light to Darkness

While studying the polarity of the *Fucales* egg, I observed in 1951 that isolated receptacles of *Pelvetia fastigiata* could usually be stimulated to discharge gametangia by exposure to a brief period of darkness following a longer period of illumination. Thenceforth, gametes of *Pelvetia* have been obtained routinely by this means. It was further observed, especially at lower temperatures, that the shedding stimulus was sometimes transmitted from one region of a receptacle to another. Since no similar observations on algae have been published, and since the *Fucales* egg is an attractive object for embryological investigation, a brief report may be of interest.

Material was collected at Corona del Mar, California. Mature receptacles were cut free at their bases, brought indoors, and allowed to become air-dry until liquid was no longer visible upon them. Then they were placed inside a covered jar which was in turn inside an ice-cooled 'Thermos' jug and transported to the Earhart Plant Research Laboratory in Pasadena, where they were stored in closed jars, still dry, in the dark, and at 6° C. Even after more than two weeks of such storage, receptacles have yielded gametes which united to form zygotes showing more than 95 per cent normal germination.

The light–dark response was found to be weak or absent in receptacles stimulated before two or three days of such storage. Therefore, after at least two days of such storage, receptacles were transferred to sea-water at 16° or at 9° C. and were illuminated by about 500 ft.-candles of white light free from infra-red radiation. Receptacles that had been stored for relatively long times often extruded some gametangia while being illuminated, but such shedding did not affect the subsequent response to darkening.

Receptacles that were transferred to darkness after two hours of illumination did not respond; but those transferred after four or more hours of illumination usually began to shed eggs rapidly within ten minutes and yielded up to 10,000 eggs per receptacle within half an hour. Examination of the process of gamete liberation with a hand lens showed the oogonia being ejected from each ostiole one at a time, often succeeding each other so rapidly as to form long rows like green beads on a string. No upper limit to the effective light period was found; darkening after as long as 450 hr. of illumination evoked shedding in the usual manner. A dark period as short as 3 min. followed by a return to the original illumination brought forth the usual shedding ten minutes later. Thus shedding may be induced by a dark period so short that the discharge of gametangia begins and continues in the light.

In some experiments receptacles were illuminated in the usual way, and then only about one-half (basal or apical) of each receptacle was darkened, the other end remaining undisturbed in the same light. The darkened ends of the receptacles responded by discharging gametangia as usual and in many cases the other, still illuminated, ends also responded. This transmission of the shedding stimulus was observed to occur to a very much greater degree among experiments conducted at 9° C. than at 16° C.

I am indebted to Dr. Frits Went and to Dr. Anton Lang for their encouragement and aid in preparing this communication and to Dr. Gilbert Smith for identifying the species used. The work reported was carried out while I held a United States Atomic Energy Commission predoctoral fellowship.

Abnormal Growths associated with Wool Follicles in Sheep

Burns and Clarkson[1] described 'capsules' in sheep skin which, when traced up towards the skin surface, were apparently degenerate follicles. Similar roughly spherical bodies have now been seen free in the dermis. These usually had lumina like the 'capsules' mentioned above and, although smaller, could presumably have arisen from degenerate follicles by disruption at a point on the longitudinal axis of the follicle. Thus, when in samples taken at different ages from various sheep breeds, these bodies were observed attached to the base of an otherwise normal follicle, usually not far above the bulb (Fig. 1), they were thought to have become secondarily attached. However, in this figure the connective tissue sheath can be seen to be split and 'pushed away' from the follicle, and in preparations stained with cyanol to show blood vessels[2] the capillary network of the follicle has been seen to extend around these bodies. This suggests that the body had, in fact, been formed as an outgrowth from the follicle and had not become secondarily attached. When one was seen in a sheep vibrissal follicle within the blood sinus, the suggestion of secondary attachment seemed untenable.

In Figs. 2 and 3 this body can be seen to be attached by a long stalk to the outer root sheath immediately below the sebaceous gland. In this instance one can see in the body a series of concentric zones having the appearance of stratum corneum. These are arranged around a spheroidal centre of homogeneous appearance which apparently contains some melanized granules. Most of the bodies, however, contain a lumen which in many instances appears to be collapsed. It is possible, therefore, that some of the bodies seen free in the skin represent outgrowths which have become detached from the follicle, and are not proximal parts of degenerate follicles. In

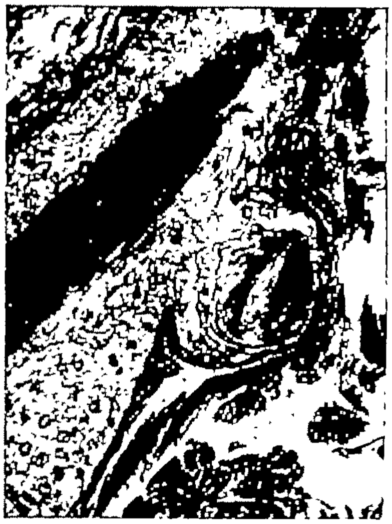

Fig. 1. Abnormal body attached to wool follicle. × c. 265

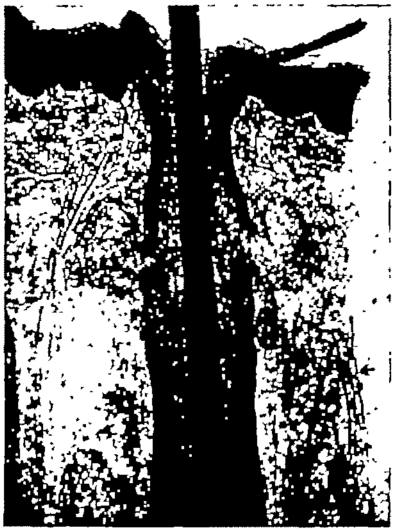

Fig. 2. Vibrissal follicle with an abnormal body. Wall of the sinus is indicated by an arrow. 150 µ frozen section. × c. 65

at least one large 'capsule' with a lumen, which may have arisen as an 'outgrowth' or from a degenerate follicle, foreign body giant cells were observed. This tends to support the suggestion that bodies with a lumen represent a later stage than those containing a central spheroid. The structures described here are smaller in size than the 'capsules' of Burns and Clarkson[1]; they are most comparable with their 'type D capsule' in which a second lumen exists for a distance up the follicle. Thus their 'type D capsule' may be identical with the bodies seen here, and may not fit in with the series of degeneration they suggested.

Certain stages of the cysts produced experimentally by Wolbach[3] in the mouse appear to be of a similar relative size to the 'capsules' of Burns and Clarkson and apparently have the same origin from an entire region of a follicle and not from an appendage.

Pinkus[4] described outgrowths of the human follicle wall in which there were keratinized 'beads'; he did not mention a lumen as observed here. It is interesting that a lumen might arise independently from the follicle lumen, and that keratinization morphologically comparable with stratum corneum might arise independently from the skin surface, as appears to happen in the formation of hair canals (cf. Wildman's[5] Plate 2). On the other hand, laminæ similar to stratum corneum might arise by re-absorption of solid keratinous structures[6].

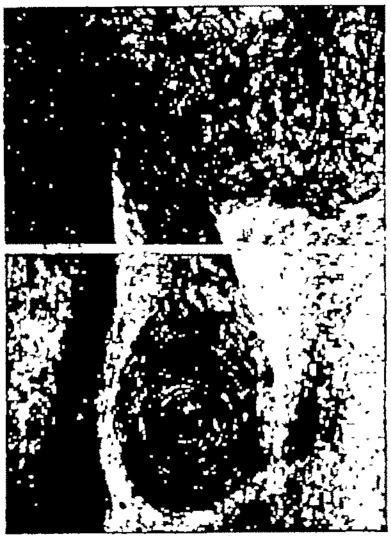

Fig. 3. Higher power photomicrographs of the body in Fig. 2. The upper one is at a focus level showing the attachment to the follicle wall beneath the sebaceous gland. The lower one shows the internal structure. × c. 300

One of us (M. L. R.) is studying the blood supply to follicles, hence the preparations to show the blood sinus of vibrissal follicles. It is noteworthy that in contrast to some other mammals (cf. Davidson and Hardy[7]) the vibrissal follicles of sheep lack a ringwulst (Fig. 2).

We are indebted to Dr. G. M. Bonser, of the School of Medicine, Leeds, for a most helpful discussion of these observations.

Our thanks are due to the Council of the Wool Industries Research Association for permission to publish these observations, also to Mr. H. M. Appleyard and Miss M. E. A. Perkin for preparing the photomicrographs.

Biological Acetylation of Isoniazid

In the course of investigations involving sulphonamide acetylation it was observed that the acetylation of sulphanilamide by pigeon liver extracts was markedly inhibited by isoniazid (isonicotinylhydrazide) (unpublished results). By means of the procedure of Lineweaver and Burk[1] the inhibition was found to be competitive in nature. The probability that the inhibition was of the competing substrate type was increased by the recent findings of Hughes[2] and others[3] that, following the administration of isoniazid to man and monkeys, 1-isonicotinyl-2-acetylhydrazine appears in the urine. It has now been found that isoniazid is readily acetylated by pigeon liver extract, and that substances which inhibit sulphanilamide acetylation also inhibit the acetylation of isoniazid.

Acetone-dried pigeon liver was prepared as previously described[4]. The dry powder was extracted by grinding in a mortar for 5 min. with a medium

Table 1. ACETYLATION OF ISONIAZID BY PIGEON LIVER EXTRACT

Additions	Isoniazid recovered (µgm.)	Isoniazid acetylated (µgm.)	(per cent)
None	316	4	1
Adenosine triphosphate	266	54	17
,, + acetate	141	179	56
,, + citrate	178	142	44

Vessel components, pigeon liver extract 1 ml. (corresponding to 60 mgm. of acetone powder), potassium phosphate buffer, pH 7·4, 0·02 *M*, isoniazid initially added 320 µgm.; other additions as indicated. adenosine triphosphate 0·004 *M*, potassium acetate 0·02 *M*, potassium citrate 0·02 *M*. All concentrations are final in a total volume of 3 ml.; 90 min. incubation at 37° C.

Table 2 INHIBITION OF ISONIAZID AND SULPHANILAMIDE ACETYLATION IN PIGEON LIVER EXTRACTS

Exp. No.	Additions	Isoniazid acetylated (μM)	Inhibition of isoniazid acetylation (per cent)	Sulphanilamide acetylated (μM)	Inhibition of sulphanilamide acetylation (per cent)
1	Isoniazid	1·51	—	—	—
	Sulphanilamide	—	—	0·90	—
	Isoniazid, sulphanilamide	1·05	30	0·30	68
2	Sulphanilamide	—	—	1·22	—
	Sulphanilamide, p-aminosalicylate	—	—	0·76	38
	Sulphanilamide, 6-aminonicotinamide	—	—	0·70	43
3	Isoniazid	1·12	—	—	—
	Isoniazid, p-aminosalicylate	0·60	46	—	—
	Isoniazid, 6-aminonicotinamide	0·58	48	—	—

Vessel components: 1 ml. of pigeon liver extract (corresponding to 60 mgm. acetone powder); 60 μM potassium phosphate buffer (pH 7·4); 60 μM acetate; 60 μM citrate; 6 μM adenosine triphosphate; other additions as indicated: Exp. 1, 2·92 μM isoniazid; 2·61 μM sulphanilamide; exps. 2 and 3, 2·33 μM sulphanilamide; 2·33 μM isoniazid; 3 μM p-aminosalicylate; 3 μM 6-aminonicotinamide. Total volume 3 ml.; 90 min. incubation at 37° C.

composed of 0·09 *M* potassium fluoride and 0·06 *M* potassium chloride in the proportion of 60 mgm. powder per ml. of extraction medium. The supernatant obtained after centrifugation at 3,000 r.p.m. for 20 min. was used as the source of acetylating enzyme.

Sulphanilamide was estimated by the method of Bratton and Marshall[5]. A modification of the chlorodinitrobenzene method of Scott[6] was used for the estimation of isoniazid. Acetylated isoniazid, which does not react with the colour reagent, was determined as the difference between the control and incubated samples. This method will be described in detail elsewhere.

As shown in Table 1, isoniazid, when incubated with pigeon liver extract in the absence of adenosine triphosphate, was almost quantitatively recovered. This indicates that isoniazid is not destroyed by pigeon liver extract and that its disappearance, therefore, can safely be attributed to conjugation. The addition of acetate and adenosine triphosphate to the system resulted in the acetylation of 56 per cent of the isoniazid initially added. Citrate as an acetyl precursor[7] was less effective than acetate. The slight acetylation which takes place upon the addition of adenosine triphosphate alone is undoubtedly due to residual acetate or acetyl precursors in the crude extract. From the point of view of acetylation, isoniazid and sulphanilamide when present together are mutually inhibitory. Thus, when 2·92 μM of isoniazid and 2·61 μM of sulphanilamide were added to the system (Exp. 1 of Table 2), a lower amount of each was acetylated than when either was present separately. This suggests that the same enzyme may be involved in the acetylation of both compounds. The same suggestion may be found in the fact that *p*-aminosalicylate and 6-aminonicotinamide inhibit the acetylation of both isoniazid and sulphanilamide (Exps. 2 and 3, Table 2).

Hughes[2] has discussed the chemotherapeutic significance of isoniazid acetylation. The inhibition of isoniazid acetylation by *p*-aminosalicylate is of some interest in this regard. The apparent synergism which obtains when isoniazid and *p*-aminosalicylate are used in combination in tuberculosis therapy[8] may be due, partially, to the inhibition by *p*-aminosalicylate of isoniazid acetylation. When isoniazid and *p*-aminosalicylate are administered in combination to rabbits, the free-isoniazid blood-levels 4 hr. after dosage are twice as high as those attained when the same dose of isoniazid is given alone (unpublished results). Bernstein *et al.*[9] have shown that acetylisoniazid has less than one-five-hundredth the activity of the parent compound against the tubercle bacillus *in vitro*, while *in vivo* the parent drug is at least one hundred times more active than the acetyl derivative. It might be expected, therefore, that *p*-aminosalicylate would be instrumental in enhancing the *in vivo* activity of isoniazid against tubercle bacillus infections by maintaining elevated and prolonged therapeutic blood-levels of free isoniazid.

The technical assistance of Mr. Julius Gordon is gratefully acknowledged.

Extraction of ACTH from Human Pituitaries

ACTH is prepared mainly from hog pituitaries for medicinal purposes, and Marshall[1] showed conclusively that it was localized in the basophil cells of the anterior hypophysis in that animal. So far as we are aware, ACTH has not been extracted previously from human pituitaries, although lyophilized pituitary tissue has been assayed[2].

Eighteen human pituitaries from cases with no evidence of a primary endocrine disorder were used for the extraction of ACTH, and all but two were removed within seven hours of death. In almost all cases a thin slice of the anterior hypophysis was taken for histological study and the posterior lobe removed. The bulk of the anterior hypophysis was then placed in deep freeze until sufficient material had been collected. The time in deep freeze of individual glands varied from a few days to six weeks.

The glands were then acetone-dried and finely powdered to give 1·30 gm. of dry powder. The powder was extracted with 75 per cent acetone at *p*H 2·0 and the active material precipitated with an excess of acetone, yielding 119 mgm. of ACTH with an activity of 2·24 I.U. ± 26 per cent per mgm.

Clearly this yield of ACTH from human pituitaries, namely, 205 u. per gm. of dry powder, is as good as that obtained from the best batches of pig glands despite the greater interval which elapsed between death and their collection. The histological changes produced in the basophils in Cushing's syndrome[3], as a result of cortisone therapy[4], in Addison's disease[5] and in conditions of stress[6], provide indirect evidence that in man, also, ACTH is formed in these cells of the anterior hypophysis. If this is the case, there is little doubt that the degranulation of the basophils occurring as a result of stress must have some influence on the yield of ACTH, and this problem is in the process of further investigation.

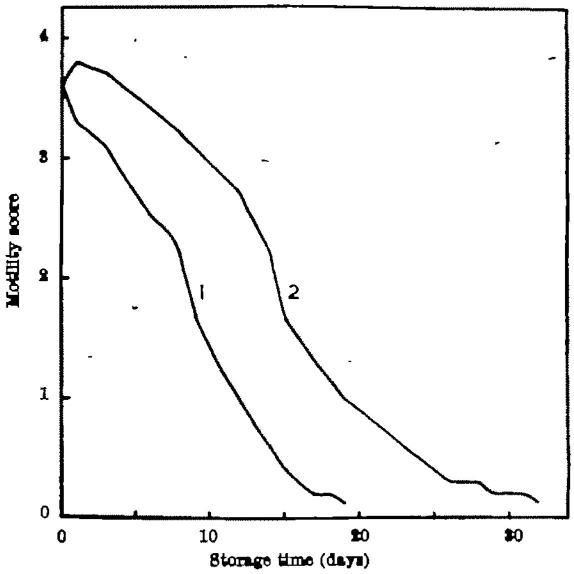
Effect of Glycine on the Survival of Bull Spermatozoa *in vitro*

Bull semen for artificial insemination is usually stored at 4° C. in media composed of equal volumes of either phosphate buffer (*p*H 7·4) or citrate buffer (*p*H 6·8) and fresh egg-yolk[1]. Under these conditions the motility and fertilizing capacity of spermatozoa decrease rapidly with time, and in practice samples are not used for insemination for more than three days after collection. Semen can be successfully stored for much longer periods at – 79° C.[2], but this technique has disadvantages for everyday use.

Since evidence has been obtained suggesting that bovine spermatozoa are adversely affected by phosphate and citrate buffers[3], attempts have been made to improve sperm survival at 4° C. by replacing these buffers (that is, the non-egg-yolk part of the diluent) with other solutions. In this connexion we have observed that sperm motility declines less slowly when the conventional citrate buffer (3·2 per cent sodium citrate) is replaced by Sørensen's glycine buffer (0·75 gm. glycine, 0·58 gm. sodium chloride, water to 100 ml.)[4]. Afterwards it was found that solutions of pure glycine, with equal volumes of egg-yolk, were more effective in bringing about this improvement and that sperm survival increased with increasing glycine concentration in the non-egg-yolk fraction up to levels of at least 4 per cent (0·53 *M*). Data illustrating the improved survival of spermatozoa stored in 3 per cent glycine–egg-yolk as compared with those stored in 3·2 per cent sodium citrate–egg-yolk are summarized in the accompanying figure. These results, mean observations on ten split ejaculates each diluted ten times, show that the decline of motility during storage is slower in glycine–egg-yolk and that the mean half-life of the spermatozoa in this diluent (as judged by motility) is increased by six days. The addition of electrolytes (sodium hydroxide, Ringer solution, 0·9 per cent sodium chloride, phosphate and citrate buffers) to the glycine–egg-yolk appears to have an adverse effect on sperm survival; on the other hand, there is evidence that the addition of small amounts of fructose and small amounts of arginine (which increases *p*H) individually increase sperm survival. In one instance a semen sample diluted with a glycine–fructose–egg-yolk medium appeared good enough for insemination after 50 days storage and still contained some progressively moving spermatozoa after sixty-five days. In all experiments, however, there has been considerable variation in sperm survival between semen samples.



Decline of motility of bull spermatozoa stored at 4° C. in (1) 3·2 per cent sodium citrate – egg-yolk, and (2) 3·0 per cent glycine – egg-yolk

Preliminary observations indicate that the survival of boar and stallion spermatozoa is also enhanced by glycine.

Tyler and co-workers[5] have shown that glycine prolongs the life-span of spermatozoa of the sea urchin, domestic fowl and bull. The mean half-life of bull spermatozoa at 38·6° C. was increased in their experiments from 5·9 to 7·2 hours by 0·038 *M* glycine in balanced saline, but there was no improvement at 4° C. and the effect of glycine in conjunction with egg-yolk was not studied. Tyler and Rothschild[6] found that the metabolism of sea urchin spermatozoa is affected by glycine although glycine is not metabolized to any measurable extent. They suggest that the beneficial effect of glycine is due to chelation of heavy metals, but if this were a complete explanation a maximal response would be expected at fairly low glycine concentrations. The present results show that maximal survival of bull spermatozoa is not obtained until the final glycine concentration, excluding that originally present in the egg-yolk, is at least 0·26 *M*, and that some property of glycine other than its chelating action must be at least partially responsible for its effect. Because electrolytes are known to stimulate the activity of mammalian spermatozoa and probably, therefore, shorten their survival, the favourable effect of glycine as compared with citrate buffer may be due to its low electrolyte content. It is also possible that as an essential precursor of certain biologically important substances such as sarcosine, creatine and adenosine, glycine plays an important part in maintaining the functional integrity of the sperm cell.

Experiments are now being carried out to determine the effect of glycine on the fertilizing capacity of bull spermatozoa.

Cultivation of *Pasteurella tularensis* in Chemically Defined Media: Effect of Buffers and Spermine

Pasteurella tularensis is generally considered to be a fastidious micro-organism, difficult to cultivate in artificial media[1,2]. Tamura and Fleming[3], in a preliminary report, briefly announced the cultivation of *P. tularensis* in a synthetic medium with cocarboxylase, adenylic acid, adenosine diphosphate or adenosine triphosphate as the critical growth factors.

With the strains at our disposal we were unable to demonstrate any growth-promoting effect of adenosine triphosphate when added to various basal media. On the other hand, we observed that addition of large amounts of acid hydrolysates of proteins such as hæmoglobin to a basal medium composed of glucose, cysteine, sodium chloride, salts *A* and *B*[4] and thiamine, enabled good growth of all the ten *P. tularensis* strains tested.

The growth-promoting effect of hæmoglobin was traced to the high histidine content of the globin moiety. In fact, graded amounts of histidine, added to a basal medium composed as above, with vitamin-free casein acid hydrolysate as source of amino-acids, produced, up to 5 mgm./ml., a nearly linear growth-response. Analogous results were obtained when casein hydrolysate was replaced by a mixture of amino-acids, similar to that described by Mills *et al.*[5], namely, *l*-arginine (200 μgm./ml.), *l*-aspartic acid (200 μgm./ml.), *l*-cysteine (100 μgm./ml.), *dl*-*iso*leucine (200 μgm./ml.), *dl*-leucine (200 μgm./ml.), *l*-lysine (200 μgm./ml.), *dl*-methionine (200 μgm./ml.), *l*-proline (1 mgm./ml.), *dl*-serine (200 μgm./ml.), *dl*-threonine (1 mgm./ml.), *l*-tyrosine (200 μgm./ml.), *dl*-valine (200 μgm./ml.) (Fig. 1).

dl-Histidine as well as *d*-histidine were found to be as effective, on a quantitative basis, as *l*-histidine, provided that the medium contained a minimal amount of *l*-histidine (50–100 μgm./ml.). This result suggested a dual function of histidine: as an essential metabolite active in its *l*-form only, and by its physico-chemical properties independent of the optical configuration.

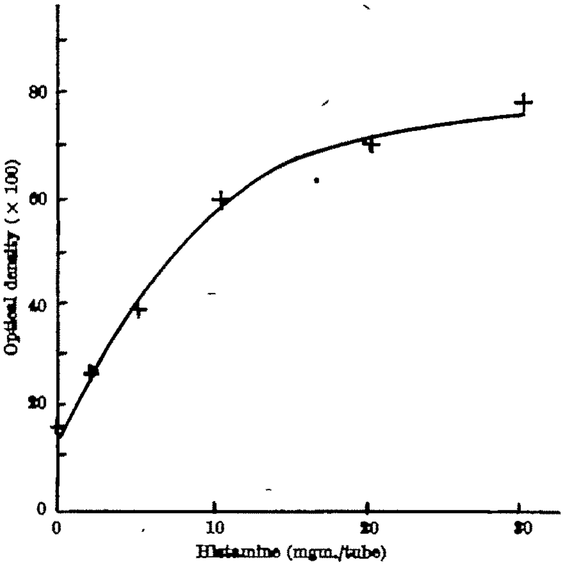

Fig. 1. Growth response of *P. tularensis* to graded amounts of histidine

Since histidine is known as a potent chelating agent, it was first assumed that its physico-chemical effect on growth may be ascribed to a metal-binding mechanism. The finding that other metal-complexing substances such as histamine and even chemically unrelated compounds like glycylglycine and sodium pyrophosphate exhibited similar growth-promoting activity appeared to lend support to this assumption (Table 1). On the other hand, it was difficult to reconcile with this hypothesis the fact that other known chelating compounds such as citrate, tartrate and versene (ethylene diamine tetraacetate) failed to sustain growth. Changing the mineral composition of the medium did not significantly affect growth.

While looking for an alternative and a more satisfactory explanation, it was noticed that all the active compounds had in common the property of being strong buffers with a *pK* value of about 8–9. This suggested the trial of other buffers of the same *pK* range such as tris [tris (hydroxymethyl) aminomethane], and diglycylglycine[6], substances which apparently do not possess any significant metal-complexing capacity. Tris and diglycylglycine proved to be nearly as effective as histidine in sup-

Table 1. Effect of Buffering Agents on the Growth of *P. tularensis* (Strain 176) in a Chemically Defined Medium

30 mgm. of each buffering agent was added to 5 ml. of basal medium. The basal medium is composed of the thirteen amino-acids mentioned in the text (histidine in amount of 100 μgm./ml.), thiamine 2 μgm./ml., 1 per cent glucose, 0·9 per cent sodium chloride, salts *A* and *B* (ref. 4). Growth was measured in terms of per cent transmission in a Coleman spectrophotometer at 550 mμ

Buffering agent added	Growth (48 hr.)
None	85
Histidine	15
Histidylhistidine	20
Histamine	15
Glycylglycine	28
Diglycylglycine	28
Sodium pyrophosphate	20
Tris	26
Salts *A*	50

porting growth of *P. tularensis*. Moreover, by increasing the concentration of the phosphate buffer (salts *A*) a definite improvement of growth was achieved (Table 1). Additional proof in favour of the buffer hypothesis was furnished by the observation that good growth could be correlated with maintenance of a constant pH of the medium at about 7–7·5, while poor growth was accompanied by a rise of alkalinity to a pH value of about 8.

The growth curve in the chemically defined media exhibited a prolonged lag period as compared with a proteose peptone broth, the final yield being equal in both media. In the search for this 'lag shortening factor' it was found that addition of minute amounts (5 μgm./ml.) of spermine or spermidine eliminated the lag and thereby abolished the observed difference between the synthetic and peptone medium. In addition, the presence of spermine reduced the amount of histidine needed. With spermine added, optimal and rapid growth could be secured by merely increasing the concentration of the phosphate buffer to 0·02 *M*. Putrescine, cadaverine and agmatine were also active, but to a smaller extent.

The mechanism by which spermine exerts its effect is being investigated. Results will be presented in a detailed report.

Neutralization of Silkworm Jaundice Virus by Human Serum

It is well known that immunized rabbit serum neutralizes the virus of silkworm jaundice, but there seems to be no information on the effect of human serum. Human sera were obtained from people working on silkworm jaundice virus and from others. Supernatant fluid from the infected larval blood was used as the virus solution. Usually the pupae injected with about 5–1,000 ml. of 10^{-6} diluted infected larval blood all died from jaundice. The diluted virus solution and an equal volume of the serum or distilled water were mixed and maintained at room temperature for 30 min. After this treatment, about 5–1,000 ml. of the mixture was injected into healthy silkworm pupae, which were observed for 10 days[1].

The results (Table 1) show that there is scarcely any difference in the neutralizing titre between sera of people engaged in work on silkworm jaundice virus and others.

But it was found that the latent periods of the pupae injected with the serum were shorter than that with the distilled water in each virus dilution as shown in Fig. 1 (final dilution of the virus is $\frac{1}{2} \times 10^{-4}$), Fig. 2 ($\frac{1}{2} \times 10^{-5}$) and Fig. 3 ($\frac{1}{2} \times 10^{-6}$). The latent period of the silkworm jaundice virus depends upon the virus multiplication[1]. Hence, in the case of injecting the virus with human serum, the virus

Electron-Track Autoradiography of Radioactive Frog Embryos

Beta-track autoradiographs offer advantages over other methods of autoradiography, especially when small quantities of weak emitters such as carbon-14 are used[1]. If, in addition, the autograph and tissue can be viewed as a unit, a further advantage is gained[2]. Such preparations permit detection of the characteristic tracks in the presence of heavy background fog; eliminate the problem of spurious interpretation due to the reduction of the silver grains by tissue constituents[3]; require far less radioactivity for detection than other methods of autoradiography; permit viewing at high magnifying power with consequent localization of radioactivity to small areas; and eliminate matching of tissue and autograph. Beta tracks, due to their tortuous path, do not permit determination of a point source.

Radioactive frog (*Rana pipiens*) ova and embryos were produced by injecting sodium formate-^{14}C into the gular lymph sac of females, which were then induced to ovulate by an intraperitoneal injection of pituitaries. Fertilized ova were permitted to develop, and specimens were fixed in absolute alcohol at various developmental stages[4], cleared in oil of wintergreen and embedded in paraffin. Serial sections were cut at 10 μ, floated on absolute alcohol on to slides coated with albumen, and dried.

For preparation of the autographs, the paraffin was removed with xylol and the slides dried at 40° C. on a warm plate. Several drops of Ilford *G*-5 emulsion gel, melted at 45° C., were placed on each warm slide, and the emulsion brushed over the sections with a camel's-hair brush held in a quill. The slides were cooled to room temperature to allow the gel to harden, placed in a lead-shielded dark receptacle for 23 days, and then developed in amidol for 15 min. (amidol, 1·5 gm.; sodium sulphite, 3·5 gm.; sodium bisulphite, 0·5 gm.; distilled water, 500 c.c.). This was followed by 5 min. in a stop-bath of 1 per cent acetic acid and then for 30 min. in hypo solution maintained at 5° C. The hypo was then gradually replaced with cold distilled water over a period of about 45 min. The slides were washed in running, cold tap water for several hours and dried overnight. The emulsion often adheres poorly to plain glass, so 5 per cent sodium sulphate should be added to the stop-bath to act as a hardening agent. However, if subbed-glass (gelatine-coated glass) is used, the hardening agent is not necessary. Subbed-glass can be treated just as plain glass slides are treated.

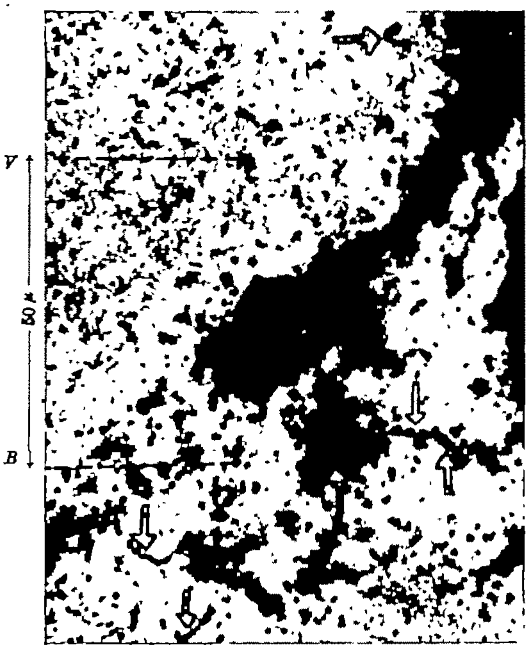

Fig. 1. Hind brain of a stage-21 larva of *Rana pipiens*, sectioned at 10 μ, showing electron tracks, some of which are indicated by arrows. *X* shows a cluster of tracks; the tissue can be seen in the background; *V* indicates the ventricle; *B* indicates the hind brain. (× 1,000)

The slides are best examined with an oil-immersion lens. Emulsion covering non-radioactive areas may show an occasional electron-track which is regarded as 'background', but emulsion covering the radioactive areas exhibits many tracks, and can thus be demarcated from non-radioactive areas.

Fig. 1 shows a portion of the hind brain and ventricle from a radioactive stage-21 larva. The tissue is out of focus, but can be seen in the background. The area in this photograph has at least forty tracks distributed in the emulsion over the tissue; but since the tracks arising from the tissue pass into the emulsion and lie in several planes, only a few can be seen clearly at any one plane of focus. One track can be seen in the ventricle at the periphery of the tissue; but beyond this area there are no electron tracks, and the radioactive area of tissue can be distinguished from the non-radioactive area of the ventricle. It is problematical that the group of tracks seen at 'X' come from a common source such as the same cell, but it can be assumed that they arose from cells in the immediate area of the field viewed.

The method of preparation outlined here loses the fatty substances of the tissue, and thus loses radioactivity. Other methods of preparation, such as freeze-drying, would preserve these and other soluble constituents. Thus, selective fixation and preparation might be used to demonstrate the presence of specified tissue substances.

Properties of the Non-Calcareous Material in the Shell of *Anodonta cygnea*

THE shell in the Lamellibranchia consists of a number of distinct layers which show a fundamental similarity in structure in related regions of valve and ligament[1]. In *Anodonta*, all parts of the shell, except the periostracum and the fusion and outer layers of the ligament, are calcified and contain a non-calcareous matrix, termed conchiolin, which in sections possesses characteristic staining properties. Conchiolin of the inner layers of valve and ligament stains typically with basic dyes, outer layer conchiolin predominantly with acid dyes, and fully-formed periostracum and fusion layer usually remain uncoloured.

A number of histochemical tests have been carried out on the shell conchiolin which indicate that it consists mainly of protein (ninhydrin, xanthoproteic, arginine[2] and Millon tests), although lipoid material (sudan black stain) and possibly some polysaccharide (periodic acid–Schiff test[3]) may be present. The detailed results of these tests indicate that there is a similarity in the properties of corresponding layers of valve and ligament and also that, as reported by Trueman in *Tellina tenuis*[4], the conchiolin of the inner layers of valve and ligament differs in composition from that in the rest of the shell. The chitosan-iodine test for chitin[5] gives a slightly positive reaction with *Anodonta* conchiolin. The periostracum, fusion and outer layers give a more strongly positive reaction to the argentaffine test[6] than the inner layers, suggesting the presence of quinone-tanned proteins. Sections treated with a series of reagents devised by Brown[7] to determine the types of linkages in structural proteins dissolve almost completely only in the sodium hypochlorite solution, providing further evidence for tanning having taken place.

The amino-acid content of the conchiolin protein has been further investigated by paper chromatography. The shell was treated in four parts, namely, 'outer' layer valve (including periostracum as well as true outer layer), inner layer valve, 'outer' layer ligament (including fusion layer as well as true outer layer) and inner layer ligament. Acid hydrolysates of equal quantities of dried conchiolin from each region were run simultaneously on paper chromatograms, using phenol/water and butanol/acetic acid/water as solvents, and developed with ninhydrin. The results reveal that although the general pattern of the amino-acids produced from each hydrolysate is somewhat similar, there are some marked differences in concentration (Fig. 1). Tyrosine is relatively more abundant in the 'outer' layers of both valve and ligament and phenylalanine is more highly concentrated in the 'outer' layer of the ligament than in the inner. Arginine and certain other amino-acids, however, show relatively higher concentrations in both inner layers. These results, and, in particular, the striking similarity in amino-acid content of the 'outer' layers of valve and ligament (Fig. 1), agree in general with the responses observed to the histochemical tests for amino-acid groups.

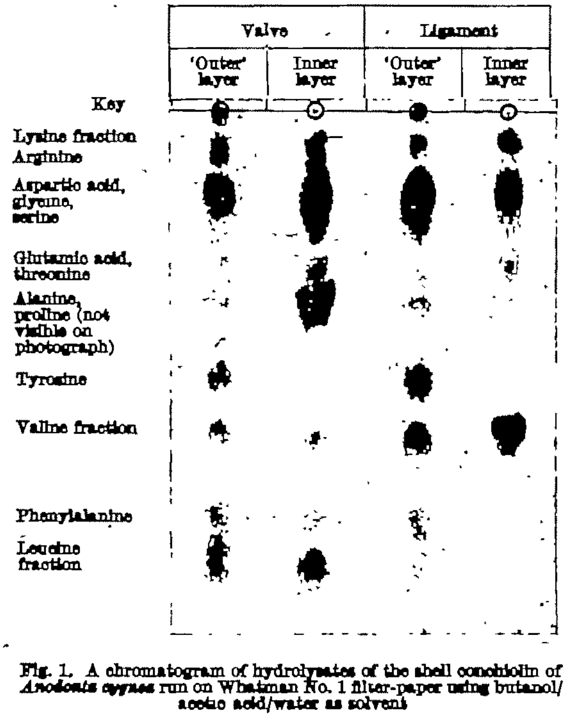

Fig. 1. A chromatogram of hydrolysates of the shell conchiolin of *Anodonta cygnea* run on Whatman No. 1 filter-paper using butanol/acetic acid/water as solvent

This work, which will be published in full later, appears to provide further evidence for the homology established on morphological grounds between the layers of valve and ligament. Moreover, the difference in composition between the conchiolin of the inner layers of valve and ligament and that in the rest of the shell, as indicated by its staining properties in sections, is reflected by the results of the histochemical tests and chromatographic analyses carried out.

I wish to thank Prof. P. G. 'Espinasse and Mr. E. R. Trueman for help and guidance and the authorities of the University of Hull for the research scholarship which has made this work possible.

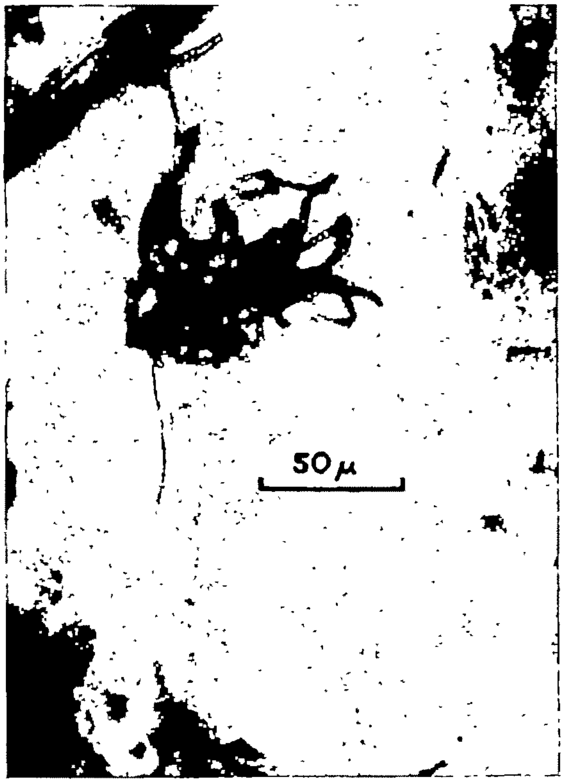
Examination of Soil Micro-organisms in their Natural Environment

PRESENT information on the distribution and growth of micro-organisms in the soil has been obtained almost entirely by plating dilute soil suspensions on to nutrient media, the Rossi–Cholodny[1] buried slide technique, Jones and Mollison's[2] soil suspension preparations and similar indirect methods. Kubiena[3] has developed methods of examining soil organisms *in situ* using reflected light, but his observations are necessarily confined to soil surfaces. So far as we are aware, the technique of preparing thin sections of soils and non-coherent rocks for microscopical examination by transmitted light has not previously been applied to the study of soil micro-organisms in their natural environment.

In the present method, standard soil sampling and rock slicing techniques have been modified with the object of keeping the soil and soil micro-organisms as nearly as possible in their natural state. This involves keeping the stresses acting on the sample small and the temperature low. Small soil samples are taken in a polythene tube fitted with a detach-



able metal shoe and are kept in the tube throughout the staining, drying and impregnation processes. Stains and wash liquids, if used, are soaked through the samples by capillarity. The sample is rapidly dried under vacuum and vacuum-impregnated at a low temperature by a drip method using a 'Marco Resin' mixture (an unsaturated polyester manufactured by Scott Bader and Co., Ltd.).

Once the resin has matured, the sample is hard enough to be cut by the usual rock-slicing techniques without disturbance and tough enough for slices 1 mm. thick to be removed using a fairly slow speed (140 r.p.m. for a ten-inch disk) and 'Carborundum' of about 100 grade. The slices are rubbed down to any desired thickness and polished using 'Carborundum' and water; they are mounted and covered with pure canada balsam.

When sampling and impregnation are carefully carried out, there is no detectable disturbance of the soil except for a little drag at the contact of the sampler and soil, and the samples are thoroughly impregnated. The accompanying photograph of a conidial head of *Aspergillus niger* van Tiegh. in an interstitial space shows that only slight disturbance of the conidial chains has occurred during sampling and impregnation.

Sections of sandy loam and sandy clay loam prepared by this technique have a moderate to high degree of translucency even at thicknesses of several hundred microns. Algæ, fungal hyphæ and fructifications, etc., in the soil pores and on the surfaces of the mineral particles are clearly visible. Fine hyaline hyphæ, difficult to see under conditions of bright-field illumination, can be seen more easily by phase-contrast microscopy. Preliminary trials suggest that staining of the soil sample before impregnation may increase the value of the method when fine hyaline mycelia and bacteria are to be studied.

The whole process from taking the sample to examining the finished slide takes two to three days—no longer than the standard biological technique of wax embedding and microtoming. The equipment required is simple and readily made up from standard laboratory materials. A more detailed description of the method will be appearing elsewhere.

The Second Ecdysis of Infective Nematode Larvæ

ALTHOUGH the second ecdysis of certain species of nematodes which parasitize sheep is known to take place in the alimentary tract of the host, the actual site is not definitely known. In the horse, some knowledge of this subject has been gained by placing larvæ in fluid from various parts of the intestinal tract[1]; but this method has not always been successful with sheep. However, it has been reported that the abomasal fluid plays a part, at least in so far as *Haemonchus contortus*[2], *Trichostrongylus colubriformis*[3] and *T. rugatus*[3] are concerned.

At this laboratory the site of exsheathment of several species has been studied in the sheep. Infective larvæ were placed in the contents of the rumen, abomasum, duodenum and ileum, and incubated at 38° C. Larvæ in 'Cellophane' sacs were also placed directly into the rumen through a rumenal fistula, and after laparotomy, into the abomasum, duodenum and ileum.

Preliminary study of the results suggests that the infective larvæ of species normally parasitic in the sheep commence to exsheath in that portion of the intestinal tract which immediately precedes the region in which the adults are normally found. *H. contortus*, *Trichostrongylus axei* and *Ostertagia circumcincta*, parasitic as adults in the abomasum, were observed to exsheath in the rumen. *T. colubriformis* and *Nematodirus* spp., parasitic as adults in the small intestine of the sheep, failed to exsheath in the rumen, but exsheathed in the abomasum, although at different rates. Whereas after an hour 90 per cent of *T. colubriformis* were exsheathed, less than 10 per cent of *Nematodirus* were exsheathed.

Oesophagostomum columbianum, a parasite of the large intestine, was not observed to exsheath in the rumen, abomasum or small intestine, although Veglia[4] has recovered exsheathed larvæ of this species from the abomasum and small intestine of the sheep.

With the exception of *Nematodirus*, larvæ normally exsheathed very rapidly, and after an hour the process may be complete in more than 90 per cent. However, considerable variations were noted in the rate of exsheathment of *H. contortus* in the rumen.

Strongyloides papillosus, a contaminant in some cultures, was observed to die if retained in the rumen for more than half an hour. This species is a skin penetrator, and its inability to survive in the rumen suggests that the success of oral infestations may be dependent on the ability of larvæ to penetrate the epithelium of the mouth, or alternatively to pass through the rumen in less than half an hour.

It is possible that the second ecdysis plays a part in determining the region of the host's intestinal tract in which the worms develop. Thus, *T. axei* is the only member of this genus to live in the abomasum, and is the only member to enter that organ exsheathed. Differences in the rate of exsheathment between *T. colubriformis* and *Nematodirus* spp. in the abomasum may be a significant factor in the relative position of these species in the small intestine, since Tetley[5] has shown that the maximum numbers of *Nematodirus* spp. are always posterior to the maximum numbers of *T. colubriformis*. The relative inability of some species of nematodes to parasitize a host, in which another species of the same genus is commonly found, may possibly be determined by differences in the rate of exsheathment within the host. Further work to elucidate these and other aspects is in progress.

I thank Mr. H. McL. Gordon, of the McMaster Laboratory, for helpful advice, and Mr. F. J. Hamilton, also of the McMaster Laboratory, for assistance with the necessary surgical operations.

Occurrence of *Paracentrotus lividus* (Lamarck) in Scotland

Paracentrotus lividus is a littoral sea-urchin well known in the Mediterranean and on the Atlantic coasts of Europe. In the British Isles it has been recorded only in Ireland, where it is common on the south and west coasts, and occasionally in Devonshire and Cornwall[1].

It is therefore of interest to place on record that three specimens were found in 1939 in the intertidal zone of the Isle of Muck, Inverness-shire. These came from two distinct localities and the animals were living in situations similar to those inhabited by *Psammechinus miliaris* in crevices and under stones. Possibly the rock is here too hard for the urchins to burrow as is their habit in so many other localities[2]. The spines, while of the typical purple colour, are shorter and stouter than in some Irish specimens in our collection. The animals resemble closely a specimen presented to one of us by the late Prof. J. H. Orton which he collected at Looe in Cornwall in 1913.

Effect of Alpha-Particle Bombardment on Creep in Cadmium Single Crystals

BOMBARDMENT of stressed single crystals of cadmium by alpha-particles was found by Andrade[1] to cause a marked increase in the rate of glide under certain conditions. The crystals were stressed so as to produce a creep-rate of about 0·05 per cent per min., and increases in rate of up to five times were recorded on bringing up the alpha-particle sources during the early stages of the creep curve. The effect was attributed by Andrade to the initiation of new glide planes by the intense local disturbances produced in the surface of the crystal during the impact of the energetic alpha-particles.

The present creep tests were undertaken to throw further light on this hypothesis, and in particular to determine if the effect occurred on clean crystals or whether a thin oxide film was necessary. The apparatus is very similar to that used by Andrade with the exception that the strain is measured with an optical-lever device having a magnification of 200. A cylindrical polonium alpha-particle source with an initial strength of 140 mc. produces a maximum flux of 5×10^8 particles per sq. cm. per sec. at the surface of the crystal. The flux used by Andrade was about $1{\cdot}5 \times 10^8$ particles per sq. cm. per sec.

It has not proved possible to repeat the phenomena described by Andrade. Tests have been carried out on both standard (99·9 per cent) and spectroscopic (99·99 per cent) purity cadmium crystals, 1 mm. in diameter under a variety of surface conditions produced by oxidizing the clean 'as-grown' crystals in the atmosphere for various lengths of time at 240° C. Crystals have been tested with a range of orientation ψ, the angle between the glide plane and the specimen axis, between 10° and 45°. The effect of dissolved nitrogen has also been investigated. The majority of the specimens have been tested at 0·05 per cent per minute—the rate quoted by Andrade—but tests have also been made at various rates between 0·013 and 0·26 per cent per min. The bombardment was usually initiated after about 0·5 per cent glide and the sources were brought up and removed from the specimen several times during the course of a test. A small elongation of the crystal sometimes occurred on moving the alpha-particle sources; this was traced to vibration in the apparatus and could be reduced to a minimum by very careful handling.

In specimens in which marked geometrical softening occurred as glide proceeded, due to the rotation of the glide planes towards the specimen axis with a consequent increase in shear stress, it was observed that the elongation produced by vibration would sometimes cause an increase in the rate of creep. This behaviour was observed in specimens in which the angle ψ was large and also in annealed crystals containing dissolved nitrogen. The increase in creep-rate under these conditions was independent of the position of the alpha-particle sources. In the majority of the tests, however, no change in creep-rate was detectable on bringing up or removing the sources from either the clean or the oxide-coated crystals.

Bombarding for longer periods under no load has been found to harden the crystal slightly. In one case the creep-rate of a clean spectroscopically pure crystal was reduced from 0·08 to 0·05 per cent per min. after bombardment for 2 hr. It is possible that this effect is due to the oxidation of the crystal by the oxygen ions or ozone produced in the air by the passage of the alpha-particles.

A full account of these experiments is being published elsewhere.

The 'Oxygen-Effect' in Ionizing Irradiation

It is a well-established fact that ionizing irradiation damages a variety of cells to a greater extent if the irradiation takes place in presence of oxygen than under anaerobic conditions. The mechanism of this 'oxygen-effect' is not yet fully understood. It is generally believed[1-4] to be due to the deleterious effect on cells by the strongly oxidizing radical HO_2 and, to some extent, by hydrogen peroxide, which are formed on X-ray irradiation in aqueous media containing oxygen, as compared with the less powerful OH radical which, in addition to reducing hydrogen atoms, is formed on irradiation in nitrogen. The exception, so far, is a bacteriophage, for which evidence has been adduced[5,6] that it has a far greater sensitivity to reducing than to oxidizing radicals.

In the work, which is reported here, bacteria representing strict and facultative aerobes and anaerobes, as well as some yeasts, were exposed to X-rays in order to study whether the 'oxygen-effect' requires the maintenance of normal respiration during irradiation and whether it bears any relation to a particular type of cellular metabolism.

Known concentrations of washed cells, suspended in phosphate buffer + glucose, were irradiated (190 kVp., no added filtration, dose-rate $6 \cdot 5 \times 10^3$ r./min.) at doses of $6 \cdot 5$–$26 \cdot 0 \times 10^3$ r. (1–4 min. irradiation). The liquid phase, during irradiation, was either free from dissolved oxygen (the gas space containing nitrogen or hydrogen) or it was in equilibrium with oxygen of decreasing percentage (100 per cent oxygen; 20 or 5 per cent oxygen in nitrogen). In some experiments with 20 per cent and 5 per cent oxygen the nitrogen was replaced by carbon monoxide. Immediately after irradiation a known amount of cells was transferred either into fresh buffer solution + glucose or into a nutrient medium in manometer flasks, and the rate of some metabolic processes measured for up to ten hours. These included: oxygen uptake, carbon dioxide production, aerobic and anaerobic fermentation or acid production and utilization of hydrogen (*Vibrio desulphuricans*). In a nutrient medium the increase, for example, in oxygen uptake or anaerobic acid production with time is proportional to the increase of dry weight of bacteria, that is, it is a true reflexion of growth.

None of the metabolic reactions measured was significantly affected by irradiation, when measured in washed non-growing cells, except aerobic fermentation of baker's yeast, which was slightly inhibited. All cells examined, however, when transferred into growth-promoting media, showed an 'oxygen-effect', that is, a stronger inhibition of growth on irradiation in presence than in absence of oxygen. The relative sensitivity for oxygen-treated as compared to nitrogen-treated samples was approximately threefold for aerobic cells, which agrees with data in the literature[1,3,4]. It was much greater, however, for a strictly anaerobic organism (*Vibrio desulphuricans*) and for spores of an aerobic organism (*B. subtilis*), which were not affected by irradiation of up to 26,000 r. in nitrogen, that is, they gave rise to vegetative forms at the same rate as the controls, while growth after irradiation in presence of oxygen (air) was strongly inhibited.

In the case of *Sarcina lutea* it has been possible to abolish almost completely the 'oxygen-effect' at doses up to 26,000 r., if cell respiration was inhibited by respiratory poisons during the irradiation. Thus, after removal of the poison, the cells behaved as if they had been irradiated in nitrogen, when judged by the degree of growth inhibition and subsequent rate of recovery. The effective inhibitors were carbon monoxide, potassium cyanide, hydroxylamine and sodium azide. Urethane did not diminish the 'oxygen-effect'.

The mode of action of the effective poisons in their role as respiratory inhibitors is known[7-9]. They all block hydrogen transfer through the respiratory enzymic system by combining with cytochrome a_3 and stabilizing the remaining respiratory enzymic chain in the reduced form. Taking this mode of action as a guide in advancing a possible explanation for the 'oxygen-effect' in irradiation, it is suggested, at least for this bacterium, that the enhancement of irradiation damage (1) involves the enzymic respiratory mechanism, (2) requires at least part of the enzymic respiratory chain to be in the oxidized form during irradiation. This makes it possible that the impedance has been caused by a reducing agent.

The results form part of a body of work which will be reported fully elsewhere.

Effects of Crystallization on the Glass–Rubber Transition in Polyethylene Terephthalate Filaments

Multifilament yarn spun from polyethylene terephthalate polymer ('Terylene' polyester yarn) is non-crystalline and almost unoriented. After drawing, it becomes highly oriented and moderately well crystallized[1], and in this state at room temperature it has a high initial tensile modulus, and recovers almost completely from strains of up to 1 per cent[2].

It has recently been suggested[3] that the mechanical and electrical transitions in a number of substituted acrylic polymers are characteristic of the molecular structure: the results which are given here of our investigation into the tensile behaviour of polyethylene terephthalate filament yarn show, in addition, that the visco-elastic properties of a given polymer can be considerably modified by molecular orientation and crystallization. In particular, a con-

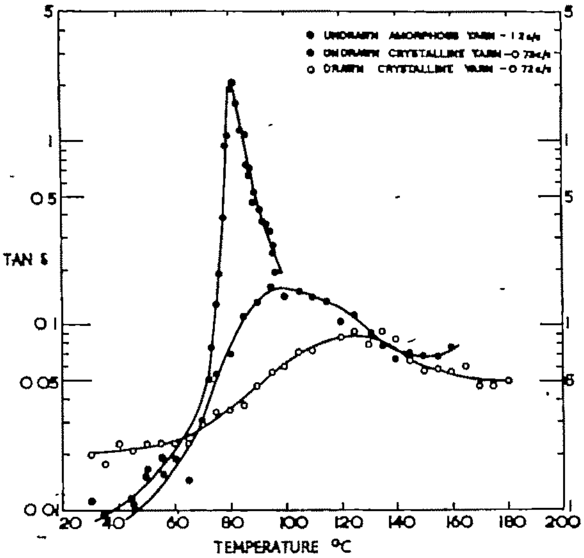
	Density (gm./c.c.)	Infra-red estimate of crystallinity[4] (per cent)	Birefringence	Transition temperature (° C.)	Half-width of loss peak curve (° C.)	Maximum value of loss tangent	Young's modulus (dynes/cm.² × 10¹⁰)	
							Below transition	Above transition
Unoriented amorphous	1·336	2	+ 0·00	81	10	2·0	1·9	0·012
Unoriented crystalline	1·383	48	− 0·01	100	70	0·16	2·6	0·29
Oriented crystalline	1·391	65	+ 0·22	125	45	0·09	12·1	3·5

siderable movement of the 'second-order transition point' has been noted.

A temperature-range of 20°–180° C. and frequencies from 10^{-3} c./s. to 10^{4} c./s. have been used, the frequency-range being divided into three sections to permit the use of convenient experimental methods. At low frequencies (10^{-3} c./s. to 10 c./s.) forced vibration was used for obtaining the load-extension hysteresis loop for strain amplitudes of up to 1 per cent. In the intermediate range (10 c./s. to 500 c./s.) the decay of free oscillations of a mass supported by the yarn is observed, while for still higher frequencies a longitudinal wave pulse propagation technique is employed. Since experimental limitations demand a decrease in amplitude with increasing frequency of vibration, it is not necessarily possible to make a direct comparison between the results from each frequency range; but there does appear to be reasonable agreement in regions of overlap.

The low-frequency range has been chosen for a detailed investigation of the effects of frequency and physical structure on the glass–rubber transition using a constant strain amplitude of 0·7 per cent. The load-extension loop is an ellipse, the slope of the major axis and the width being determined by the Young's modulus and the phase difference between the load and the applied extension (loss angle). The temperature dependence of these two quantities is used to determine the position and nature of the transition.

For all the yarns tested, the modulus decreases with increasing temperature, and the resultant tension becomes increasingly out of phase with the applied extension, until the foot of the sigmoidal modulus–temperature curve is reached, when the phase difference decreases again. In undrawn, amorphous filaments, this 'glass–rubber' transition is sharply defined by a drop of a factor of 100 in Young's modulus, whereas drawn crystalline filaments have a much broader transition with only a fourfold drop in modulus, occurring at a higher temperature.



The effect of increasing frequency is to increase the modulus and change the loss angle in the transition region, so that the maximum loss angle occurs at a higher temperature. For undrawn amorphous or slightly crystalline filaments this shift in loss peak is about 3·5° C. per decade, corresponding to an apparent activation energy of 170 k.cal./mole, whereas for highly crystalline drawn filaments the figures are 7° C. per decade and 90 k.cal./mole.

Increasing the crystallinity of undrawn yarn results in a broadening of the loss angle curve and a shift of its peak towards higher temperatures, together with a considerable reduction in its peak value, while the Young's modulus at temperatures above the transition region is considerably increased. The curves are further modified in a similar way in the more highly crystalline drawn yarn, the relative data being given in the accompanying table. This briefly summarizes the major influence of orientation and crystallization upon the physical properties; the two effects, however, cannot be completely separated owing to their close interdependence. The diagram shows the effect of crystallinity and orientation on the loss angle–temperature curves.

It is hoped to publish this work in more detail elsewhere.

Magnetic Susceptibility of Vanadium Dioxide

We have found that the reduction of vanadium pentoxide (V_2O_5) as described below gives a form of vanadium oxide (VO_2) which has not the magnetic discontinuity (at 341° K.) reported in the literature[1,2].

Reduction of vanadium pentoxide, prepared from 'Analar' ammonium metavanadate, with hydrogen below 530° C. yields a blue-black powder. Oxide compositions in the range $VO_{1\cdot92}$ to $VO_{2\cdot3}$ have been prepared in this way and their magnetic susceptibilities measured in a nitrogen atmosphere. The compositions were checked from (i) the loss in weight on reduction from the pentoxide, (ii) the quantity of hydrogen used in reduction, and (iii) by titration with permanganate before and after measurement.

The oxides were examined in the range 20°–450° C. and the values of mass susceptibility χ_m of the vanadium oxide present, assuming them to be mix-

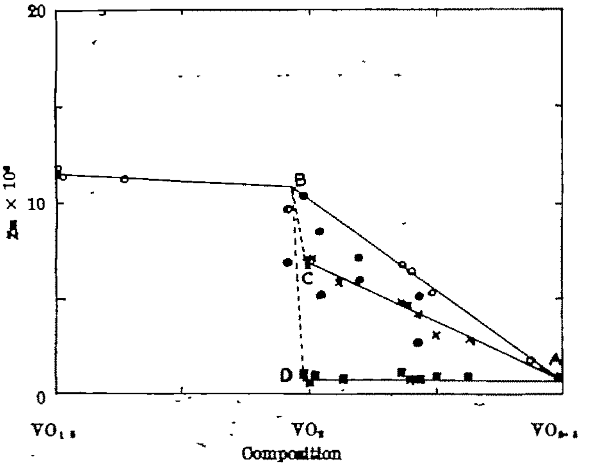

Fig. 1. Mass susceptibility of vanadium oxides. ○ (no discontinuity), at 340° K.; ● and ◑, at 335° K., 345° K., respectively (discontinuity at 340° K.). The line *AB* fits the points ○. Results for sintered oxides. □ (at 335° K.) and × (345° K.) for the various compositions. Lines *AD* and *AC* fit these points fairly well

tures of VO_2 and V_2O_5, were plotted for each oxide and above 345° K. were found to obey the Curie–Weiss law:

$$\frac{1}{\chi_m} = \frac{T - \theta}{C_M}.$$

Only slight discontinuities were noted at 340° K., and the values of θ and p_B (derived from C_M) for the V^{4+} ion were in the ranges $\theta = -350°$ to $-450°$ K. and $p_B = 1\cdot8$ to $2\cdot2$ Bohr magnetons for observations above 345° K. The results are plotted in Fig. 1.

These values were not inconsistent with the theoretical value of $p_B = 1\cdot73$ for the spin only state of V^{4+}.

The actual values of χ_m were generally too high (for example, $VO_{1\cdot90}$, $\chi_m = 9\cdot15 \times 10^{-6}$ at 335° K.; $11\cdot15 \times 10^{-6}$ at 345° K.; and $VO_{1\cdot8}$ $\chi_m = 13\cdot9 \times 10^{-6}$ at 335° K.) for these oxides to be mixtures of V_2O_3 and V_2O_5. They show no ferromagnetism.

When the oxides $VO_{2\cdot0}$–$VO_{2\cdot2}$ were fused at 750° C. in nitrogen, or V_2O_3 and V_2O_5 were fused together in the appropriate proportions at 750° C. in nitrogen, in a sealed silica tube, the resulting crystalline oxides had large discontinuities in susceptibility at 341° K. similar to, but more pronounced than, those reported by Perakis and Wucher[2]. The susceptibility curves were exactly reversible on cooling down again through 341° K. The V^{4+} ions in these oxides gave $\theta = -1,200°$ to $-1,400°$ K. and $p_B = 2\cdot8$–$3\cdot1$ Bohr magnetons, above 345° K. The value of $p_B = 3\cdot0$ corresponds to the presence of an unquenched orbital contribution in addition to the spin contribution. The values of χ_m for $VO_{2\cdot00}$ were $1\cdot2 \times 10^{-6}$ at 335° K. and $7\cdot75 \times 10^{-6}$ at 345° K. with the main discontinuity at 341 ± 2° K. The results for sintered oxides are plotted in Fig. 1.

The existence of a sharp increase in electrical conductivity and a decrease in thermoelectric e.m.f. (cold junction negative throughout), when the temperature rises from 330° to 350° K., has been noted for the fused $VO_{2\cdot00}$. No sharp changes in these properties have been observed for the powder form of this oxide.

These results suggest the existence of two different forms of VO_2, depending on whether the oxide has been sintered during preparation or not. This is in line with the results of Flood and Kappa[3] on vanadium oxide prepared by sulphur dioxide reduction of the pentoxide. We are unable to agree with these authors that VO_2 is formed in this latter process, as samples we have prepared at 480°–640° C. all analysed as $V_{12}O_{26}$ (allowance being made for any sulphur dioxide adsorbed on the final oxide). Rate measurements indicated that some sintering occurred between 600° and 640° C., however.

It would appear that oxygen can be removed from the V_2O_5 lattice until the composition VO_2 is formed; but the rutile structure is not attained unless the temperature is raised above about 620° C.

The results of Perakis and Wucher[2] suggest that the oxide they examined was a mixture of the two phases, and the non-reversible curve obtained on cooling after heating suggests either oxidation or a change in the proportions of the two phases. All our curves were reversible on cooling, except when the measurements were extended above 400–450° C. (in nitrogen).

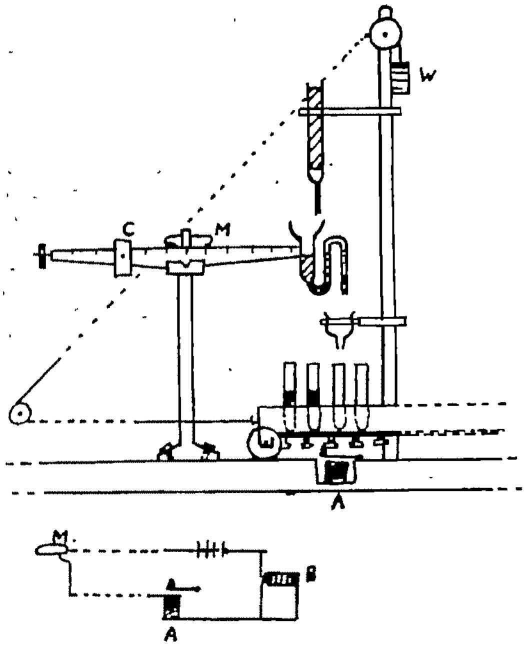
Simple Automatic Fraction Cutter

The automatic fraction cutter described below is of extremely simple design and inexpensive to make, and yet works as efficiently as any commercial model. In contrast to those which have been described previously[1,2], where a twisted string provided motive power, this cutter uses a descending weight, which is not only more dependable but also can be readily adjusted.



The column delivers into a small siphon attached to one end of a balance beam, and a counterweight C on the other side of the beam is used for adjustment. A mercury switch clipped to the top centre of the beam makes contact when the weight of liquid in the siphon tilts the beam. At the moment contact is made, a relay A underneath a trolley of test tubes is operated, and a lagged relay B, taking small current, switches this off very quickly afterwards. The trolley is moved along one division in this time by a weight, W, and pulley system. The siphon empties shortly after this, thereby releasing relay B; but this simply switches off the current and there is no movement of the trolley. During this time, and while the siphon is refilling, any last drips from the siphon are collected in the same tube.

The trolley in use has only sixteen holes drilled for test tubes spaced 1¼ in. apart. The design of the trolley may easily be modified to take more tubes or even flasks if a larger volume is required. Beneath the holes a strip of ¼-in. steel has been drilled and tapped for 16 6.B.A. 'cheesehead' bolts which connect with the catch of relay A.

The volume that the siphon delivers can be adjusted with glass beads, and the counterweight moved accordingly.

Measurement of Small Differential Pressures at Low Absolute Pressures

In the course of a study of the flow of gases through powders at reduced pressures, it was necessary to be able to measure pressure differences of the order of 1–60 microns mercury in the absolute pressure range 1–100 microns mercury. Such small pressure differences have been measured by using two McLeod gauges, and the method has been reported elsewhere[1]. It was found that pressure differences of a small order could not be accurately measured using two separate McLeod gauges, even when a cathetometer was used for reading the mercury levels. Consequently, an alternative method and apparatus were developed and their principles are described here.

The apparatus (Fig. 1) consists basically of two McLeod bulbs connected on each end of a capillary oil manometer. The pressure difference applied between A and B is initially shown as a minute difference in the levels of the manometer filled with high-vacuum oil. Mercury contained in the reservoirs driven by the atmospheric pressure fills the bulbs and encloses the volumes of gas above the level YY. The final mercury level is reached at XX (approximate height of mercury 76 cm.). Thus the gas which originally occupied the bulbs and capillary tubes up to the level XX is compressed into the capillary manometer tubes above the oil. In the apparatus built in our experiments the compression ratio was about 20 : 1, thus increasing the observed differential pressure about twenty times, which was easily read with the cathetometer.

A simple theory of this apparatus is as follows. Let the actual pressure drop be $\Delta p = P_A - P_B$.

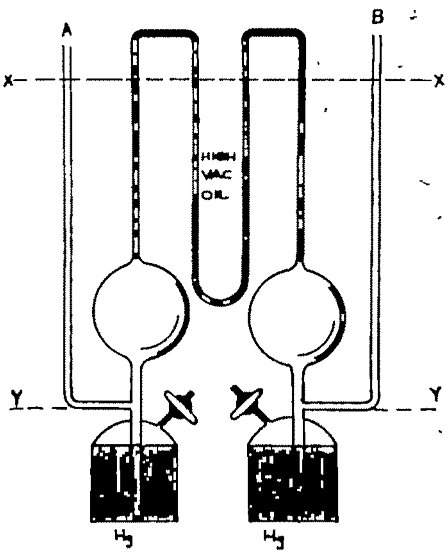

Fig. 1

Left-hand side : V_1 = volume of bulb + capillary between the levels XX and YY.

V_2 = volume of capillary between XX and oil level.

Right-hand side : V_3 = volume of bulb + capillary between the levels XX and YY.

V_4 = the volume of capillary between XX and oil level.

When the gas is compressed by raising mercury into the bulbs and up to the level XX, the following relation applies :

$$P_A\,(V_1 + V_2) = P_A'V_2\,;\ \text{that is, } P_A' = \frac{V_1 + V_2}{V_2}\,P_A$$

$$P_B\,(V_3 + V_4) = P_B'V_3\,;\ \text{that is, } P_B' = \frac{V_3 + V_4}{V_3}\,P_B$$

If $V_3 \approx V_2$ and $V_4 \approx V_1$ and $V_2 \ll V_1$;

$$\Delta p' \approx \frac{V_1}{V_2}\,\Delta p.$$

Hence the actual pressure drop Δp can be magnified by the ratio of the volumes of the bulb to that of the capillary manometer.

When $(V_3 - V_2)$ and $(V_4 - V_1)$ are not zero, then a plot of $\Delta p'$ versus Δp at different values of P_B will give the value of the expression :

$$\frac{(V_3 - V_2) + (V_4 - V_1)}{V_2}\,.$$

The differential pressures at low pressure may thus be obtained either from the final equation or from a graph and converted into the mercury readings applying the known density ratio of mercury to the oil.

In order to ensure complete pressure equilibrium, a period of ½–1 hr. was allowed to lapse between the compression of the gas and the final measurement of the oil levels. The method itself gives very reproducible results and is simple in operation.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, October 18

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Electricity in the Future".

Physical Society, Acoustics Group (in the Physics Department, Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 5.30 p.m.—Mr. N. Fleming: "Techniques for Objective Noise Measurement".

Institute of Metal Finishing (at the Northampton Polytechnic, St. John Street, London, E.C.1), at 6.15 p.m.—Dr. R. R. Kressman: "Ion Exchange in the Metallurgical Industries".

Royal Institute of Chemistry, London Section (at Dartford Technical College, Dartford), at 7.30 p.m.—Mr. W. S. Wood: "Manufacture and Uses of Hydrogen Peroxide".

Tuesday, October 19

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. H. E. Lewis: "The British North Greenland Expedition, 1952–54".*

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. F. H. Allen, Mr. W. A. Price and Sir Claude Inglis, F.R.S.: "Model-Experiments on the Storm Surge of 1953 in the Thames Estuary and the Reduction of Future Surges".

Institution of Electrical Engineers, Measurements Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. M. Whitehead: Chairman's Address.

University of London, British Postgraduate Medical Federation (in the Beveridge Hall, Senate House, London, W.C.1), at 5.30 p.m.—Prof. A. V. Hill, F.R.S.: "Why Biophysics?" (From a series of lectures on "The Scientific Basis of Medicine".)*

Society of Chemical Industry, Plastics and Polymer Group (in the Rooms of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. C. H. Bamford: "Recent Investigations in the Field of Vinyl Polymerization".

Institution of Mechanical Engineers, Steam Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "Measurement of the Wetness of Steam".

Royal Society of Medicine, Pathology Section (at 1 Wimpole Street, London, W.1), at 8.15 p.m.—Prof. L. P. Garrod: "Chemicals versus Bacteria" (Presidential Address).

Wednesday, October 20

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. H. Harris: "Biochemical Genetics".*

Royal Meteorological Society (at 49 Cromwell Road, South Kensington, London, S.W.7), at 5 p.m.—Scientific Papers.

Royal Society of Medicine, Comparative Medicine Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Sir Weldon Dalrymple-Champneys: "Non-specific Physiological Factors Controlling the Phenomena of Parasitism" (Presidential Address).

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. S. Chandrasekhar: "Infant Mortality in India, 1901–1951—a Demographic Revolution".*

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. J. N. McArthur: "A Contribution to Microscope Design".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 7.45 p.m.—Mr. Engel Lund and Mr. Ferdinand Rauter: "Folk Songs of Many Lands".*

Thursday, October 21

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. P. E. Hodgson: "Nuclear Disintegration".*

Physical Society and the Institute of Physics (at the Research Laboratories of the General Electric Co., Ltd., Wembley), at 2 p.m.—Joint Colloquia on "Modern Materials for Thermionic Cathodes".

Medical Research Council (at the National Institute for Medical Research, Mill Hill, London, N.W.7), at 5 p.m.—Dr. J. H. Hanks (Harvard Medical School, Boston): "The Application of Metabolic Study to Leprosy Research".

Institute of Refrigeration (joint meeting with the Low Temperature Group of the Physical Society, at the Science Museum, South Kensington, London, S.W.7), at 5.30 p.m.—Dr. N. P. Allen: "The Properties of Metals at Low Temperatures".

University of London (at Birkbeck College, Malet Street, London, W.C.1), at 5.30 p.m.—Prof. R. S. Krishnan (Bangalore): "Colloid Optics" (University Lectures in Physics. Further Lectures on November 24 and 25).*

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. B. S. Platt: "Protein Malnutrition". (From a series of lectures on "The Scientific Basis of Medicine".)*

Society of Chemical Industry, Road and Building Materials Group (in the Lecture Hall of the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. P. M. Davidson: "The Manufacture and Applications of Glass in the Building Industry".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. R. B. Heisch: "Epidemiology of an Outbreak of Kala-azar in Kenya".

Textile Institute (at 10 Blackfriars Street, Manchester 3)—Symposium on Transactions Papers.

Friday, October 22

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. W. van Krevelen (Holland): "Heterogeneous Reaction Processes. 2: Gas-Solids Reaction Processes".*

Society for Analytical Chemistry, Physical Methods Group (joint meeting with the London Section of the Royal Institute of Chemistry, in the Physical Chemistry Laboratory, South Parks Road, Oxford), at 7.15 p.m.—Dr. J. E. Johnston: "Assay Equipment for a Radiochemical Laboratory"; Dr. D. E. Palm: "The Determination of Gamma Isomer in Crude Benzene Hexachloride by a Carbon-14 Isotope Dilution Method"; Mr. R. H. Burns: "The Physical and Analytical Control of the Radioactive Effluent from A.E.R.E., Harwell".

Saturday, October 23

British Psychological Society, Education Section (at the Institute of Education, Malet Street, London, W.C.1), at 2.30 p.m.—Mr. G. T. Sare: "Cybernetics and Teaching".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Kenneth P. Oakley: "Piltdown Man".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with an honours degree in mining and preferably with practical experience in the mining industry) in Mining Engineering—The Registrar, The University, Nottingham (October 23).

Mathematician (with a good honours degree, and preferably with some practical experience in the design of experiments), to design and analyse laboratory and small-scale plant experiments—The National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting TT/851 (October 23).

Scientific Officer (with a good honours degree in botany or agricultural botany) at the hill research farm of the Hill Farming Research Organization, Sourhope, Roxburghshire—The Secretary, Hill Farming Research Organization, Broomhouse Drive, Edinburgh 11 (October 23).

Assistant Experimental Officer (with a pass degree or at least the general certificate of education at advanced level) in the Plant Breeding Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (October 25).

Lecturer (with a good honours degree) in Physics, and a Lecturer (with a good honours degree) in Botany, at Fourah Bay College, Sierra Leone (University of Durham)—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (October 25).

Lecturers (2) (with a good honours degree) in Physics at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (October 25).

Assistant Lecturer (with special qualifications in pure mathematics) in Mathematics—The Registrar, The University, Manchester (October 30).

Lecturer in the Department of Clinical Chemistry—The Secretary, The University, Edinburgh (October 30).

Lecturer (with a degree in engineering and preferably with experience or interest in some aspect of heavy power electrical engineering such as modern methods of system analysis or some aspects of electrical design) in Electrical Engineering, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London (Australia, October 30).

National Research Development Corporation Scholarship tenable in the Computing Machine Laboratory—The Registrar, The University, Manchester (October 30).

Lecturer in Anthropology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, October 31).

Assistant Lecturer in Bacteriology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (November 1).

Assistant Lecturer (with an honours degree with good qualifications in agricultural chemistry, chemistry or biochemistry, and preferably with previous experience of teaching or research in soil science) in Agricultural Chemistry—The Registrar, The University, Reading (November 1).

Chair of Islamic Archæology—The Dean, Faculty of Arts, Cairo University, Cairo (November 1).

Chair of Animal Husbandry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, November 6).

Senior Research Officer or Research Officer (with a degree in veterinary science and postgraduate research experience in bacteriology or immunology, or equivalent qualifications) at the Animal Health Research Laboratory, Commonwealth Scientific and Industrial Research Organization, Parkville, Victoria, to carry out researches on approved aspects of bovine contagious pleuro-pneumonia and to take over the supervision of bovine production—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 201/74 (November 6).

ASSISTANT LECTURERS (with special qualifications in physical chemistry) IN CHEMISTRY—The Registrar, The University, Manchester (November 13).

LECTURER (graduate with some experience of teaching, and preferably with a higher degree suited to the training of teachers) IN EDUCATION, at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, November 15).

SENIOR LECTURER IN PHYSICAL CHEMISTRY at Canterbury University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, November 15).

SENIOR LECTURER IN PHYSICS at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Hong Kong, November 30).

BIOCHEMIST (Senior grade) (preferably with experience of recent methods used in general medical clinical biochemistry)—The Medical Superintendent, Morriston Hospital, Swansea.

BRADFORD DYERS' ASSOCIATION RESEARCH FELLOW (with high qualifications in science) to undertake research in tinctorial chemistry, textile chemistry, or an allied subject—The Principal, Technical College, Bradford 7.

CHEMISTS (with an honours degree in chemistry, chemical engineering, A.R.I.C., A.M.I.Chem.E. or equivalent qualifications), at Windscale Works, Sellafield, Cumberland, to undertake experimental work on chemical and chemical engineering problems in connexion with the development of new chemical processes—The United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 676.

ELECTRONIC ENGINEER or PHYSICIST, to assist in installation and operation of an electronic digital calculator—The Secretary, Birkbeck College, Malet Street, London, W.C.1.

EXPERIMENTAL OFFICER or ASSISTANT EXPERIMENTAL OFFICER (graduate in physics or chemistry) required for the Soil Survey of England and Wales, to work on clay mineralogy by X-ray and thermal methods—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

HYDROLOGISTS (with an honours degree in applied science or engineering and at least two years postgraduate experience) in the Public Works Department, Kenya, for investigations of surface and underground water resources, including stream gauging, studies of rainfall and run off, and of ground water reservoirs, etc.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.112/7/01/T.

JUNIOR LECTURER (graduate in science, agricultural science or horticultural science) IN INORGANIC CHEMISTRY AND SOIL SCIENCE at Massey Agricultural College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1.

MECHANICAL ENGINEERS, AERODYNAMICISTS, PHYSICISTS, an ELECTRICAL ENGINEER, a CHEMICAL ENGINEER, and a MATHEMATICIAN (with a first- or second-class honours degree or equivalent qualification in an appropriate subject) at the Ministry of Supply National Gas Turbine Establishment, near Farnborough, Hants—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.272/54A.

METALLURGIST (with an honours degree in metallurgy, A.I.M., or equivalent, and with considerable industrial experience, preferably in both the ferrous and non-ferrous fields), to advise on all metallurgical problems arising in the design, manufacture and inspection of specialized plant, including nuclear reactors, and to maintain liaison between design offices, other headquarters groups, and various research and development laboratories—The United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 685.

PHYSICIST (with a first- or second-class honours degree or equivalent in physics) at the Ministry of Supply Radar Research Establishment, Malvern, Worcs, for the design of high temperature electronic components for guided weapons, for use under severe vibration and climatic conditions—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 265/54A.

PHYSICIST (with a good honours degree in physics and at least two years research experience, and ability to extract information from laboratory records, repeat experiments and write suitable articles for the technical press)—The Delawarr Laboratories, Oxford.

RESEARCH ASSISTANT IN THE DEPARTMENT OF CHEMICAL ENGINEERING to investigate certain aspects of the inflammability of gases—Dr. J. H. Burgoyne, Imperial College of Science and Technology, London, S.W.7.

SCIENTIFIC OFFICERS (with a first- or second-class honours degree in physics, electrical engineering or mathematics) at the Royal Aircraft Establishment, Farnborough, Hants, for theoretical and experimental work on flight instruments for high speed aircraft, and investigations into stability and control of aircraft when flown with automatic pilots, etc.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.264/54A.

POWER AND INFLUENCE IN THE MODERN STATE

THE autobiography which Lord Beveridge published last year under the title "Power and Influence"* is, like that of Lord Reith published earlier†, of historical interest. Both books fail to throw as much light as might have been expected on the developments with which their authors are most closely and enduringly associated: Reith, because his greatest achievement was to him of little interest compared with his brief career in ministerial office; Beveridge, in part, because the origins of the Beveridge Report were left to be told more fully in Lady Beveridge's subsequent book. They are, of course, authoritative in their particular fields, but through them both runs a note of disappointment and frustration. While this may sometimes lead the reader to ask questions about our ability to make use of talent, it also induces reflexions on the theme around which Beveridge in particular has written his book, and indeed about the whole nature of government, the way it works, the limits of autocracy and democracy, the place of the expert in democracy, the efficacy of discussion and persuasion and the adaptation of society to the new powers and influences to which it is subjected by technological change. It is not the frustration, which Reith and Beveridge are inclined to take tragically, that leaves the dominant impression, but the deeper issues that are opened up by the title Lord Beveridge chose for his book, and that lie at the root of the functioning of democracy in a world in which such immense concentrations of power are possible. To the questions of leadership in the modern State, the source of power and the process of influence, Lord Beveridge's book is highly relevant, and it may be surmised that if either he or Lord Reith were induced to lecture on leadership, they might contribute some dicta at variance with those hitherto enunciated in the Walker Trust Lectures.

The conceptions of leadership which find expression in these two books, to some extent complementary, are indeed imperfect or incomplete. Lord Beveridge does not seem to appreciate how closely this question of leadership is related to his theme. Power, as he uses the word, means ability to give to other men orders enforceable by sanctions, punishment or control of rewards, and—especially the power of government—the making and enforcing of laws, using the instrument of fear. He recognizes that if power is to be used for good, it must be guided by reason and accompanied by respect for other men, and that in any advanced society there is also the power of money, working through self-interest—greed rather than fear. By influence, on the other hand, he means changing the actions of others by persuasion and by appealing to reason or to emotions other than fear or greed; and to him the instruments of influence are words, spoken or written, while for influence to be for good it must rest on knowledge. Influence, in fact, is set in antithesis to power as the alternative means of getting things done. They are not seen as complementary. Influence, it is true, is not government, but Lord Beveridge suggests that the pursuit and exercise of power do not consort naturally with the pursuit of knowledge or the appeal to reason.

---

* "Power and Influence". By Lord Beveridge. (London: Hodder and Stoughton, 1953.) 30s.

† "Into the Wind". By Lord Reith. (London: Hodder and Stoughton, 1949.) 25s.

Power as a means of getting things done appeals to that which men share with the animals, to fear and to greed; it leads those who wield it to desire it for its own sake, not for the service it may render, and to seek its continuance in their own hands. Influence, on the other hand, he argues, as a means of getting things done, appeals to that which distinguishes men from animals; and the way out of the world's troubles to-day is to treat men as men, to enthrone influence over power, and to make power revocable. It is no longer more knowledge that the world chiefly needs: power is now in the hands of men whose intentions, by any standard of respect for humanity, justice and freedom, are suspect.

Although Lord Beveridge considers the heart of the world's problem to-day is to find the right means of controlling the exercise of power and securing a place for influence, and asks some pertinent questions about democracy and the exercise of power in a democracy by particular groups, his antithesis between power and influence seems to lead him astray. It was one of his own staff at the London School of Economics who laid it down as a principle of legislation that the channels of assent could not be dug too deep, and the problem of the responsible exercise of power turns in part on this question of assent or persuasion and discussion.

Even more, it turns on personality, and this factor Lord Beveridge tends to discount or ignore. When he writes, "to use on administration the time of a great teacher or researcher is misuse of rare faculties; it is misuse which men of the highest gifts as a rule take care to avoid", he is directing attention to a danger to which scientists at least, as Sir Cyril Hinshelwood's address at the British Association meeting in Edinburgh testified, are increasingly conscious. But it is only one side of the truth. Harm and waste would equally result if no such men brought to the task of administration the imaginative insight which only their genius can confer. Government is more than administration, and administration is something more than the mechanical organization of work, the breaking up of complex tasks into simple processes, the assignment of responsibility and the provision of means for accomplishing the task assigned, to which Lord Beveridge appears to limit his conception.

In this mechanical aspect of administration Lord Beveridge himself excelled; but the government or leadership of men demands also something else, which John Buchan expressed so admirably in his lecture on Montrose and leadership and which, more prosaically, is embodied in Lieutenant-Commander A. H. Leighton's principles for the governing of men. This communication of purpose, this vision or contagion of greatness is the essence of leadership, and it springs from that indefinable personality in which Lord Beveridge is not interested as such, for all the affinity between his own definition of the art of leadership—"making common men do uncommon things"—with that of Buchan. That factor cannot be ignored in any study of government, of the relations between power and influence. Without it, integrity, intellectual ability and the capacity for sustained hard work can be ineffective—the tools of tyranny as readily as of freedom. Nor without it is experience alone likely to engender that sense of timing and of what is appropriate and possible which lies at the root of wise administration and government by consent. To arrive at a solution of this problem of power and influence, we must at least consider the processes by which such gifts are developed or acquired and also the conditions under which they are most effectively exercised. No reader of Lord Reith's "Into the Wind", for example, could imagine that the author was lacking in personality, or that he underrated the factor which Lord Beveridge discounts. The clue to Lord Reith's frustration is to be sought rather in the conditions in which personality is exercised, and his book might equally suggest an inquiry into the nemesis of power.

The right relations of power and influence turn as much on this question of personality as they do on the relations between knowledge and power. The task of government at any level to-day, from the international to the local level, involves increasingly the wise use of experts. Decisions and policy must be based on accurate knowledge and technical considerations, though not solely on these. If, however, such considerations are ignored, or the facts wilfully disregarded, disaster may well ensue.

The real challenge of the atom bomb or the hydrogen bomb comes into this context; only secondarily is it a moral challenge. Primarily it is a challenge to the hard thinking required to reshape institutions and policies to take full account of facts that do not consort with the form or practices in which ideas or prejudices have been expressed. If the expert is to be used effectively, he must himself give some attention to the expression of his ideas and to the persuasiveness with which he presents his conclusions as to the kind of policy that his expert knowledge suggests.

For this reason we require not merely experts, in spite of our need of more expert knowledge than ever; we also need men and women with personality, with faith and courage. It is curious that Lord Beveridge, who recognizes clearly enough that, behind his theme of power and influence lies this factor of change and the shaping of institutions and society to meet the needs of a new situation in which action and policy must be determined by knowledge and not prejudice, sees a somewhat false dichotomy between the scientist and the administrator or statesman. His view that the scientist is necessarily unpractical and indecisive will certainly be challenged, nor does it follow that those whose whole energies are spent in advocating some practical reform need be unscientific. The latter depends in part on whether the reform they advocate is based on knowledge rather than prejudice or whim, and in part on the outlook their training has given them. If, indeed, members of Parliament cannot be scientific and impartial, the prospects of democracy are indeed dim.

Lord Beveridge, it is true, insists that to acquire something of the scientific spirit is vital, and one remark he makes in relation to the chairmanship of the Unemployment Insurance Statutory Committee, which he held during 1934–44, is apposite: "In a world of regulations and controls it seems increasingly worth while to give to those subject to control a chance of expressing their views neither to a preoccupied Minister nor to a permanent official, but to a body of just men with time and independence and the right of making their judgments known". He sees, in fact, as the title of his epilogue tells us, that democracy, which has nothing to say about equality, but refers solely to power and the control of power, is a matter of mental climate. What he does not fully recognize is that the real issue is between two different tempers of mind—the spirit and temper of accommodation and the spirit and temper of intransigence; and his view of the way in which such climates of opinion are formed and changed is colourless and mechanical, lacking the vital quality of personality.

That quality is important, moreover, for yet another reason. The extent to which technical factors enter into sound political decisions means that the efficiency and even the possibility of government depend upon the removal of many such decisions from the range of popular choice. Even when the electorate is competent to make a sound choice, security considerations, as, for example, in the development of the hydrogen bomb and other atomic weapons or guided missiles, may make it impossible for the electorate to be given all the information required as a basis for wise decisions. To some extent that applies to its representatives in Parliament, and that is one reason for viewing with concern the growth in power of the political party system and the tendency to restrain Government policy and decisions within limits set by purely party bodies outside Parliament rather than on the corporate feeling of Parliament itself.

What has to be recognized is that any such removal of decisions from the control of Parliament exercising its corporate sense of the public interest is just as real a threat to liberty as the domination of Parliament by a single class or party. The distinguishing feature of the British constitution hitherto has been he practice of government by discussion between epresentatives who both possessed the confidence of he people and were free from their detailed control. f a new system is to be evolved or substituted in which decisions and policy are determined by technical considerations and expert knowledge, whether scientific or not, the implications must be faced and n attempt made to solve the problems of persuasion nd consent. Failure to do so will destroy the spirit f accommodation and lead to intransigence and tyranny just as surely as the attempt to make Parliament the instrument of a single class or section, sterilized against the conception of the public interest.

There is a further point also which Lord Beveridge has missed. Whether power is gained by accident or design and wielded brutally or responsibly, influence can only be won, and it is exercised continually by personal impact: it is dynamic not static, as so many professional associations forget. This point has a vital bearing on the responsible exercise of power and the place of the expert in government, and Sir Ernest Barker's analysis in his "Reflections on Government" goes much deeper than some current discussions on the adaptation of Parliamentary procedure and organization to the needs of to-day.

In the first place, we need to distinguish between the authority of the expert and that of the government itself. The first resides in the knowledge of the expert in the particular field in which he is qualified, and within which he has both the right and the duty to speak. It is an authority based on knowledge, and limited to that particular subject. The second resides in the competency of a person or body of persons to issue compulsory orders in the political field, and depends on the fulfilment of the conditions under which it was given and the cogency of those conditions in changing political circumstances. It depends accordingly to some extent on sound judgment, based on experience, rather than scientific knowledge, as to the continuing validity of the conditions under which the authority was originally given.

While the personal factor comes in at this stage on the political or government side, on that of the scientific expert it comes in at a different level. First, information, however authoritative in regard to even the most important particular field, must necessarily be compared with, and adjusted to, information in regard to other fields. No issue in politics falls within one field of science and one only. It is here, however, that the claim of the scientific expert is commonly misunderstood. It is not a claim as such to a place in the task or authority of government: it is a claim that those responsible for the task of government should be qualified and competent to assess the significance of particular scientific or technical factors, and to evaluate them along with the other factors involved in matters of public policy.

Second, not only is the information supplied by the expert in regard to his field confined on the whole to knowledge at that particular time: in the main it deals with measurable things, with questions of fact. It is quantitative and is not intended to solve problems of action, other than setting limits within which action is possible. The solution of such problems, which is the task of government, depends on more than the measurement of data and the results which such measurements can give. It may involve also the extrapolation of data to assess the probability of change within the time factor involved in political action. It involves at least a process by which the different but immeasurable claims of right and acknowledgments of duty are made sufficiently commensurable for adjustment to one another and are set to give information about themselves and in so doing to reconcile themselves to one another in a mutually acceptable solution.

Obviously, the scientist can only make his full contribution through those who possess not only an understanding of the way in which science works, but also sufficient knowledge to assess the validity of recommendations coming from within a particular field. Such persons must combine personality with their general or particular scientific knowledge, and they must also have a clear perception of the limits of scientific and technical knowledge and of the way in which the methods of open discussion and voluntary agreement function in a parliamentary democracy.

As Sir Ernest Barker points out, democracy which rests merely on the will of numbers rests merely on force. When, for example, a parliamentary government ceases to take account of public opinion or of parliament as a whole and reflects purely the views and wills of the party in a majority, it verges on the autocracy of a totalitarian regime. It ceases to be a democracy in the sense in which that word has hitherto been employed in Britain. The force which democracy can employ is inadequate merely as force, because democracy must consort with, as it is based upon, the free and full development of personality. It is not the majority, as a majority, that matters, but each human being as such; and the form of government which we have to find to-day is one which so far as possible elicits and enlists the thought, will, and general capacity, not of a majority but of every member. Such a government depends on mutual interchange of ideas, on mutual criticism of the ideas interchanged, and on the common and agreed choice of the idea which emerges triumphant from these processes. In such a government the influence of the scientific expert can be exerted in the way that is required and that consorts with the method of science itself. It will be a government which rests not on force or on numbers or even on knowledge, but on the spiritual quality of the processes by which it operates; and the effectiveness with which it works depends above all on the personality of those to whom the functions and authority of government are entrusted and the persuasiveness with which they can continuously enlist the understanding, goodwill and participation not of a minority—or even of a majority—but of all the governed.

DE BROGLIE ON QUANTUM THEORY

The Revolution in Physics

A Non-Mathematical Survey of Quanta. By Louis de Broglie. Pp. 310. (London: Routledge and Kegan Paul, Ltd., 1954.) 18s. net.

LOUIS DE BROGLIE has a unique place in the history of science as the man who in 1923 propounded the hypothesis of the wave character of material particles and thereby initiated the great movement of thought concerned in the passage from the 'old' to the 'new' quantum theory. His ideas also led directly to vital technical developments represented, in particular, by the invention of the electron microscope. Since then, besides carrying on his own scientific work, he has taken a leading part in scientific education and administration in France. In addition, he has attained eminence as a scientific writer. The present book is a translation by Ralph W. Niemeyer of one of his most notable expository works (with certain additions). Apparently the main text was written in 1936 and revised in 1946, and a few sections added in 1952.

The book may be described as an exposition, following the historical development, of the whole of quantum theory excluding (apart from brief references) the modern quantum theory of fields and modern nuclear theory. The treatment is strictly non-mathematical, but some descriptive indication is given of the mathematical structure of the theory. The work will appeal to several classes of reader. Presumably it is intended primarily for the general scientific reader, other than the mathematician or physicist, who seriously wants to understand the "revolution in physics" that has taken place in the present century. Such a reader will be well rewarded for the attentive study that the author's thorough explanations invite from him. But, since something like classical physics and something like quantum physics must always be necessary, not only for the sake of their appropriate applications, but also on account of the very nature of physical experience, it is essential to understand as well as may be the relation between these two systems; and since a special feature of the book is the statement of this relation as it stands at present, it should also be of much service to the present-day student of physics. Finally, in view of the central part played by the author himself, the book has special significance as a historical record. In this regard, it can be read as an interesting supplement to the recently published second volume of Sir Edmund Whittaker's "History of the Theories of Aether and Electricity", which also supplies the documentation not included in M. de Broglie's account.

Even in describing his own accepted contributions, M. de Broglie avoids the use of the first person singular. He reserves this form of expression for the statement of a few individual speculations and criticisms. These serve to remind us that, great as have been the successes of the theories described, the "revolution in physics" must never be assumed to have resulted in a settled régime.

W. H. McCrea

AN ASSORTMENT OF PROTEINS

The Proteins

Chemistry, Biological Activity, and Methods. Edited by Hans Neurath and Kenneth Bailey. Vol. 2, Part A. Pp. x+661. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1954.) 14 dollars.

THE nine articles that make up this third volume of a four-volume work are, for the most part, good; the information contained in them is well selected and the authors generally approach the statements they are reporting in a pleasantly critical manner. It is therefore more than usually important to consider what the advantage is of having all the articles bound together in one volume, for the consequent restriction on their distribution would matter less if it were not so obvious that much valuable time has gone into the writing. Papers appear higgledy-piggledy in scientific journals by tradition; because their classification would probably involve the editors in unnecessary argument; and because separate reprints are generally looked on by librarians as awkward things to handle. Some of the same arguments justify disorder in annual reviews and similar publications; their contents are united by their ephemeralness and little more is needed. The shortest article here runs to only twenty-five pages, which is perhaps too short to justify separate publication, but two of them run to more than a hundred pages and they would have made admirable books along the lines of the "Monographs on Biochemistry" that were such a valuable feature of the first third of this century. Had they come out in this form it is certain that they would have found more purchasers and probable that they would have found more readers.

Markham and Smith give a clear account of the history of research on the nucleic acids, nucleoproteins and viruses; and they point out how often apparently new methods had already been used by the older worker. Their criticisms of recent work are in the main valuable, though sometimes a little facile. The section on bacterial viruses is particularly good because it brings out the nature of the actual observations made; these have often recently been lost sight of in a fog of interpretations.

Work on the oxidizing enzymes has been more thoroughly integrated than any other part of biochemistry. Singer and Kearney classify it under the four main prosthetic groups, copper, pyridine nucleotide, flavine nucleotide and thiamine. They are careful to avoid the generalizations that loom so large in less specialized text-books and emphasize the importance of always mentioning the source of an enzyme in its name. Enzymes from different sources often have widely different properties though catalysing the same action, and the stress laid on this will help to focus attention on the nature of the minimum structure needed to bring about an action.

A straightforward, if pedestrian, article on respiratory proteins is followed by van Heyningen on toxic proteins. This is a well-planned account of an unusual subject; the main criticism of it is that some of the physiological and zoological jargon will not be comprehensible to chemically trained readers. He discusses critically the mode of action of these toxins, the evidence that they are useful to the organisms making them on account of the properties that we investigate, and the dangers underlying the assumption that, because a protein can do something, that is necessarily what it does do *in vivo*. McMeekin, on milk proteins, is less successful in resisting the allure of teleology. His article, and also the two on egg and seed proteins, brings out clearly the manner in which protein preparations, which appear to be homogeneous by two or three different criteria, are often shown to be inhomogeneous by the application of a third or fourth. The general recognition that homogeneity is not a property that can be demonstrated in proteins because it is, strictly speaking, only the absence of a defined type of inhomogeneity, is one of the most satisfactory aspects of research during the past decade.

Steward and Thompson have a completely different conception of the general character of the book from that shared by most of the other contributors. Their article is called proteins and protein metabolism in plants, but it is in fact a comprehensive and uncritical review of the greater part of the broader field of nitrogen metabolism in plants and much of it is only tenuously connected to proteins. If it makes more biochemists aware of the value that a plant's metabolic plasticity has in research, it will be useful.

Finally, Li describes the protein hormones in a straightforward and factual way. In the section on insulin he discusses species differences and the extent to which an activity can be shared by several different structures. It is a pity that this point, so well emphasized by Singer and Kearney, is not stressed for the other hormones too. There is generally no clear statement whether those made by different organisms are supposed to be identical or not.

The editors are to be congratulated on a book nearly free from printing errors, but they seem to have made little attempt to prevent overlapping or to put in cross-references where it does occur. There is, for example, more about the L-amino-acid oxidase of snake venom in the chapter on oxidizing enzymes than in that on toxic proteins, but neither mentions the other. To revert to the argument in the first paragraph of this review, one possible advantage of binding several articles in one volume has therefore been missed. Those who think of buying only one volume out of the four, because their tastes are catered for by the accidental grouping of articles in it, have been partly defeated by the editors. They have reserved the index for the last volume. The adequacy of the index cannot therefore be commented on.

N. W. PIRIE

THE WAY OF SEX

Sex and the Nature of Things

By Dr. N. J. Berrill. Pp. 256. (London: Victor Gollancz, Ltd., 1954.) 13*s*. 6*d*. net.

Reproduction and Sex

By Dr. G. I. M. Swyer. (Survey of Human Biology.) Pp. viii+280. (London: Routledge and Kegan Paul, Ltd., 1954.) 25*s*. net.

THESE two books are complementary and are both excellent expositions. Neither is meant for specialists, so biologists and endocrinologists should avoid them; but those whose subjects lie in other directions will find them enjoyable. Dr. Berrill's reminds one of those pleasant essays which Sir Ray Lankester published in the days of our youth, called "Science from an Easy Chair". However, his were on general biological topics, whereas Dr. Berrill's is really a history of the evolution of sex from the most primitive appearance of it as hermaphroditic reproduction in tunicates to the complication of placentals.

In some ways, Dr. Berrill disagrees with the usually accepted theory. For example, he believes that the giant reptiles, such as the dinosaurs, were exterminated by an increase in the temperature rather than by cold. It was this which caused the evolution of mammals by the shedding of reptilian scales, the development of sweat glands, and the growth of hair as an insulating medium, the production of heat by the muscles and the control of its loss by the nerve supply to the cutaneous blood vessels. He suggests that the first mammals were nocturnal animals because of their dull coloration and lack of colour vision, which contrasts with the birds and reptiles.

However, the book is not primarily concerned with such theories, interesting though they are, but with the evolution of sex, and he deals at length with the choice of a mate, mating behaviour, sexual dances of birds, and the sexual conduct of reptiles and mammals.

I have noticed only one tiny slip. On p. 128 Dr. Berrill suggests that a man's interest in the female disappears when he has insufficient male hormone; this is not necessarily true—it is, however, a triviality.

Dr. Swyer's book is not concerned with the evolution but with the manifestation of sex in the human. He gives first of all an outline and then goes on to describe reproduction in the male, the function of the adrenal cortex, and the female reproductive cycle. After this he deals with disorders of menstruation and the climacteric, and then with anomalies of sexual development. He describes conception, pregnancy and its special problems, childbirth and the problems associated with it, and breast feeding. He gives a chapter on fertility and infertility. Finally—most unusual in a book of this kind—Dr. Swyer devotes space to the psychological side of sexual behaviour and its development as well as the sexual anomalies and disorders. There are two appendixes: one on the anatomy of the reproductive organs and one on tubal patency.

There are innumerable popular books on the physiology of sex, but what makes Dr. Swyer's different from the usual 'outline' is that it is written by a specialist who is not only an endocrinologist, but also is consultant to the obstetric department of a large London hospital. He is thus able to approach the exposition of his subject with an intimate knowledge of both endocrinology and obstetrics, which the usual 'popularizer' lacks. The masterly way in which he explains the more complicated elements of female endocrinology in such conditions as menstruation, pregnancy and lactation makes his book well worth reading. Medical men who have lost touch with recent developments of sexual endocrinology could use his volume as a useful introduction; but it is so clearly written that it should be comprehensible to any educated person.

Once the subject of sex was regarded as scarcely a topic to be studied by the layman and not quite respectable. We have fortunately passed by such foolishness, and books such as these show that the ordinary man can be properly informed as to how sex was evolved and how it works. He will find the whole subject fascinating. CLIFFORD ALLEN

ASPECTS OF BIOCHEMISTRY

Essentials of Physiological Chemistry

By Prof. Arthur K. Anderson. Fourth edition. Pp. vii+480. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 40*s*. net.

Dynamic Aspects of Biochemistry

By Prof. Ernest Baldwin. Second edition. Pp. xx+544. (Cambridge: At the University Press, 1952.) 30*s*. net.

General Biochemistry

By Prof. Joseph S. Fruton and Prof. Sofia Simmonds. Pp. xii+940. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 80*s*. net.

It would be difficult to find three such dissimilar books dealing with the same branch of science. In the handling of the subject-matter and in the scope of presentation each book differs sharply from the others, but each has its own distinctive part to play in the biochemical literature.

Prof. Anderson's book is an elementary text of moderate size which first appeared in 1935 and which has now demonstrated its popularity, particularly in the United States, by reaching its fourth edition. It is essentially a book in which the beginner is introduced to biochemistry by the classical sequence of chemical structure of carbohydrates, lipids and proteins, their digestion, their metabolism and the excretion of the final products. The bias is heavily in favour of animal biochemistry, the physiological side is stressed—and rightly so in an introductory text—and the book is thus set to the level of the second-year medical student.

For the reader who has mastered Anderson—or its equivalent—Baldwin is the next logical step in his biochemical education, and the second edition of this remarkable book will be greeted with all the greater interest since the first edition achieved the unusual distinction of becoming a biochemical best seller. In spite of Prof. Baldwin's contention that this book is an elementary text-book, the reviewer cannot agree that it is an introduction to the subject, for the story does not begin at the beginning, and the reader who has not progressed to Baldwin from a more elementary text will soon find himself in difficulties. The book, moreover, does not attempt to cover the whole field of biochemistry, but deals briefly but comprehensively, at what is essentially an intermediate level, with the very body and bones of the subject—enzymology and metabolism, using the latter word in its broadest sense. The loose ends in the first edition have been tidied up and recent developments, including energetics, have been included with the same characteristic clarity and vigour of presentation as made the first edition so widely popular. In spite of the minor weakness due to the inadequate size of the bibliography, Baldwin's "Dynamic Aspects" has by now reached such an established place that no biochemical education is complete without it.

While Baldwin deals with aspects, Fruton and Simmonds cover the whole field, at what might be called a sophisticated level. As befits a text for advanced students, it plunges straight into the proteins before progressing through the enzymes and biological oxidations to a detailed study of intermediate metabolism. To attempt to write a comprehensive advanced treatise on a subject which is advancing and changing with disconcerting speed is a formidable task which few have attempted, but which has in this case been achieved with outstanding distinction. Of the two salient features of the book, one is its characteristic freshness of presentation; the authors have been fettered by none of the classical traditions which tend to stamp a pattern of uniformity on older books of a similar type, but have covered modern biochemistry in the way which seems to them—and to the reviewer—to be logical and systematic. The layouts of formulæ, figures and diagrams are entirely modern. The other characteristic feature is the wealth and breadth of documentation with chapter and verse given for each statement up to a remarkably recent date. Yet this comprehensive treatment of a big subject is compressed into 900 very readable pages. This book deserves to go through many editions—if the authors are prepared to face the formidable task o quinquennial, or even more frequent, revision.

J. N. DAVIDSON

THE ASSOCIATION OF APPLIED BIOLOGISTS (1904–54)

By R. W. MARSH
Research Station, Long Ashton, Bristol

ON November 8, 1904, Mr. Walter Collinge, of the University of Birmingham, called a meeting in the rooms of the Linnean Society, London. The seven workers interested in applied biology who attended agreed to the foundation of the Society that is now known as the Association of Applied Biologists. At this first meeting a total of twenty-seven original members was elected: they included Sir Ronald Ross, Sir Arthur Shipley, Prof. A. H. R. Buller, Prof. Maxwell Lefroy, Prof. F. V. Theobald and Mr. Cecil Warburton, now a centenarian and the only remaining survivor of the group of original members.

When the Association was inaugurated, applied biology was the pursuit of a few scattered workers, most of whom had other official duties. The first British appointments specifically for research in applied biology had been made within the previous two years at Rothamsted and Long Ashton. From 1905 until 1909 a major aim of the newly formed Association was to bring to the notice of government and university authorities the existence and potentialities of applied biology. To achieve this aim the Association became a peripatetic body, holding meetings in Birmingham, Liverpool, Cambridge, London, Edinburgh, Oxford, Manchester and Dublin. Among the subjects discussed in these early years were cereal breeding, the American gooseberry mildew, the Isle of Wight disease of bees, the larch sawfly, and the feeding habits of British birds. By 1909 the proselytizing activities of the Association had induced the enrolment of 132 members and had gained widespread recognition of the importance of applied biological research in the national economy.

This recognition was given tangible form in the constitution of the Development Fund by Parliament in 1909 with an allocation of £2,900,000 for aiding and developing agriculture and rural industries. In 1911 the Commissioners appointed to administer the fund adopted a scheme for the establishment of research institutes, the provision of technical advice, the support of research outside the institutes and the establishment of a scholarship scheme for training scientific workers. These provisions made a secure basis for the enlistment of a number of professional applied biologists, which, in its turn, was reflected in the increased activity of the Association.

By 1912–13 it was felt that the Association would function more satisfactorily if its headquarters were in London and if the existing arrangement whereby members published in the privately owned *Journal of Economic Biology* could be terminated. Stimulated particularly by the energy and vision of Prof. Maxwell Lefroy, the Association launched in May 1914 its own journal, the *Annals of Applied Biology*.

In its new role as a publishing society, the Association was almost immediately confronted with problems arising out of the First World War and its aftermath. With much difficulty, the publication of the *Annals* was maintained; but the other activities of the Association virtually ceased during the war period. The years 1918–21 were marked by recurrent financial crises threatening catastrophe, from which the Association was saved only by the resolute efforts of Prof. W. B. Brierley. He restored the stability of the Association and became editor of the *Annals of Applied Biology* in 1921. For the next twenty-five years, Prof. Brierley piloted the *Annals* to its position of unquestioned prestige.

A second period of major expansion in applied biology followed the 1921 repeal of the Corn Production Acts when, as a solatium to the farming industry, £850,000 was allotted to agricultural education and research in the ensuing five years. Within the agricultural research institutes and the advisory services many developments that had been held in abeyance since 1914 were thus facilitated, and the membership of the Association rose to 250 by 1925. During the next decade the expansion of the Department of Scientific and Industrial Research, the grants made by the Empire Marketing Board, and the attention paid to Colonial agricultural development all led to increases in the number of appointments in applied biology, reflected in demands for more meetings of the Association and for increased provision for publication.

In consequence, the activities of the Association from 1922 to the end of the inter-war period showed steady expansion. In addition to the four meetings or symposia held annually in London—where the Imperial College of Science and Technology has generously acted as host to the Association since 1917—one or more provincial and field meetings were arranged each year at centres throughout the British Isles. The *Annals of Applied Biology* was expanded from a volume of 359 pages and 14 plates in 1922 to one of 940 pages and 51 plates in 1937.

During the Second World War the expansion of the Association continued; but Prof. Brierley had to meet the problem of maintaining the publication of the *Annals* in spite of drastically reduced paper supplies and rising costs. He overcame these difficulties so successfully that at the end of the War it could be recorded that the *Annals of Applied Biology*, almost alone among British scientific quarterlies, had maintained the issue of four numbers a year in unbroken succession. During the War, the printing order for each issue remained restricted to seven hundred copies: this figure has now risen to 1,800.

Membership of the Association, now approximately seven hundred, includes on an equal footing research, advisory and teaching workers in government service and in industry, in Britain, the Commonwealth and Empire, and in many other countries throughout the world. The interests of the members, which are reflected in the *Annals of Applied Biology*, include all aspects of plant pathology (in its widest sense), the problems relating to stored products, plant and animal physiology and the application of statistical methods in biology.

Over the past fifty years the ever-increasing diversity of the elements making up applied biology has emphasized the need for bridging and integration in this field. The correlation of pure science with practice and the maintenance of the links between the interests included in applied biology has been and remains a major contribution made by the Association to the advancement of scientific knowledge.

JUBILEE CONFERENCE ON SEPTEMBER 13–17

THE Golden Jubilee of the Association of Applied Biologists was celebrated by a programme of lectures and symposia held at the Imperial College of Science and Technology, London, during September 13–15, followed by visits to research stations on September 16 and 17. Registered members of the Conference numbered 430, including 62 from twenty-one countries outside the United Kingdom.

At the opening meeting in the Jehangir Hall of the Imperial Institute, the president, Prof. William Brown, read the messages that had been sent to H.M. the Queen, to Prof. W. Brierley, and to Mr. Cecil Warburton, the only surviving original member of the Association. After giving a brief history of the Association, he welcomed the members and visitors. Dr. E. Gram (Denmark) responded on behalf of the visitors from Europe, and Dr. Starr Chester, replying for the North American visitors, conveyed the greetings of the American Phytopathological Society.

The inaugural address was delivered by Sir John Russell on "The Changing Problems of Applied Biology". Sir John recalled the early developments of the subject: the writings of Berkeley, Curtis and Miss Ormerod, the pioneer course in agricultural chemistry given by Prof. Liveing at Cambridge in 1891, and the establishment of Wye College under A. D. Hall in 1894.

In tracing the subsequent advances in applied biology, he attached major importance to the effects of the growth of technological organic chemistry that started during the First World War. Among the repercussions of this development were the far-reaching advances in all aspects of the work on crop protection products and growth-regulating substances. Another major impetus was given by the work of R. A. Fisher on the application of statistics to applied biology. The study of virus diseases of plants formed an outstanding example of advances in a field that was completely unexplored fifty years ago.

Sir John stressed the danger that specialists in applied biology may easily lose touch with each other, a danger that the work of the Association has done much to avert.

The guest lecturer on the evening of September 13 was Prof. E. C. Stakman, of the University of Minnesota. Taking as his subject "Progress and Problems in Plant Pathology", he emphasized the gravity of plant disease losses in an underfed world and listed the major contributions made by plant pathologists in reducing these losses.

Dealing with the control of black rust of wheat, Prof. Stakman showed that the eradication of 260 million barberry bushes in the United States between 1918 and 1941 had restricted the number of important races of the rust in North America to four. Wheat varieties resistant to these strains were bred and provided a satisfactory solution of the rust problem from 1938 until 1949, when the new race 15B attacked the hitherto rust-resistant varieties.

Prof. Stakman dealt with the possible means of origin of such new races from uredospore crosses. In maize smut, which can be grown in culture, mutant forms can be induced by using uranium nitrate, and these show a range of pathogenicity and of resistance to fungicides.

Prof. V. B. Wigglesworth (Cambridge) gave the evening lecture on September 14 on "The Contribution of Fundamental Research to Applied Biology". He attributed most practical advances to empirical attack, the function of fundamental research being to contribute fresh outlooks stimulating new methods of approach. A major difficulty in supporting basic research lay in the impossibility of determining which ideas would lead on to fruitful results. Karl Pearson, for example, writing in 1892, had selected the newly-described Hertzian waves—the waves of radio—as one discovery that could never be of any practical value.

The increasing cost of research work has made universities more and more dependent on the funds provided by the research councils, which are naturally aiming at practical objectives. There is therefore a danger of the neglect of fundamental research in biology, with the consequent loss of the source of new ideas. Prof. Wigglesworth commended the suggestion of Prof. Paul Weiss in the United States, that organizations supporting applied research should devote a fraction of their budgets to the cost of completely unfettered fundamental studies.

The closing lecture was delivered by Dr. K. W. Neatby, director of the Canadian Department of Agriculture Science Service, on "The Application of Biological Research to Canadian Agriculture and Forestry". In a survey of the history and organization of applied biology in Canada, he stated that the preponderating contributions were made by workers in government service—applied biology is still a relatively neglected subject in Canadian universities.

After dealing with problems of insect balance in orchards and climatological factors in tree diseases, Dr. Neatby described a method used at Ottawa for accelerated wheat breeding, enabling three generations a year to be raised in controlled-temperature chambers. The baking quality of small amounts of the newly-bred wheats can now be rapidly assessed by measuring the expansion of balls of fermenting dough in weak salt solution, and milling properties are to be tested in a micro-mill which is being constructed to produce flour from less than an ounce of wheat.

The remaining papers presented at the Conference were grouped into ten symposia. The topic of "International Co-operation in the Field of Crop Protection" was introduced by Mr. W. C. Moore (Plant Pathology Laboratory, Harpenden). As an example of progress already made, he referred to the International Plant Protection Convention, sponsored by the Food and Agriculture Organization in 1951 and now accepted by forty countries undertaking to collect and exchange phytopathological information, to carry out plant health inspections and to issue export certificates conforming to an agreed standard. The European Plant Protection Organization has since 1950 studied and recommended means of restricting the spread of pests and has organized the campaigns against the Colorado beetle.

These campaigns were described by Dr. V. E. Wilkins (director-general of the European Plant Protection Organization). He recounted the early devices for arousing public interest and showed the benefit derived by Britain from the reduction of infestation in the Cotentin peninsula and in the Pas de Calais. Eradication of the musk rat in Holland is also being attempted by the Organization. The fall webworm (*Hyphantria cunea*) spread in 1951 from Hungary to Yugoslavia, where it caused defoliation of fruit and forest trees. By 1953 the control campaign had averted the threatened spread of this pest to the rest of Europe.

Dr. E. Gram (State Plant Pathology Institute, Denmark) surveyed the problems of preventing the introduction of pests and diseases on plants sent from one country to another. He considered that air transport of plants and the world trade in grain need more supervision by plant health authorities. Dr. Gram advocated an extension of pest and disease surveys, of field inspection services and of fumigation before shipping. Improvements in these matters should make it possible to simplify some of the present quarantine procedures.

In the symposium on "Insect Pests of Stored Products", Mr. F. R. Cann, of the Infestation Control Division, Ministry of Agriculture and Fisheries, spoke on the biological aspects and economic problems of the entomology of stored products in temperate countries. He divided these pests into three groups—hose endemic in Britain, pests introduced from other temperate countries, and those arriving from the ropics. The 'temperate group' increases very rapidly in the warmer months and their attacks can be reduced by cool storage (40–50° F.). Some introduced tropical species, such as Pharaoh's ant, can continue to breed in bakeries and other heated buildings.

Dr. E. A. Parkin (Pest Infestation Laboratory, Department of Scientific and Industrial Research, Slough) reviewed progress in the control of insects infesting stored foodstuffs. After stressing the importance of cleanliness and order in the food-store, he surveyed developments in fumigation by ethylene oxide, methyl bromide and chlorinated hydrocarbons; he then dealt with the use of contact insecticides—pyrethrum, DDT, 'Gammexane' and inert mineral dusts. Concerning future developments, Dr. Parkin considered that the biggest gain would come from focusing attention on the biology and behaviour of a particular insect in specific products.

Dr. D. W. Hall, from the same Laboratory, dealt with problems of food storage in tropical countries. Here, major difficulties arise from the unsuitability of the traditional types of storage and the lack of rained staff. After only five years work, considerable advances have been made in Africa in developing methods of storing grain in sealed pits and in silos. Fumigation under gas-proof sheets has been successully applied to groundnuts in Nigeria since 1949 and is now being adopted for maize in Tanganyika and Nyasaland. Efficient storage techniques in the tropics are essential as a defence against malnutrition nd famine.

A symposium on "Plant Viruses and Virus Diseases" was held on the morning of September 14. Dr. Kenneth Smith (Agricultural Research Council Plant Virus Research Unit, Cambridge), surveying past nd present trends in plant virus research, said that two outstanding advances have been the recognition f latent infections and the proof of virus multiplication within the insect vector. Since 1935 the focus has been on the virus itself, facilitated by the electron microscope. Progress is now being made in determining the part played by nucleic acid in virus multiplication.

Prof. E. van Slogteren (Laboratory for Bulb Research, Netherlands) spoke on serological diagnosis of plant virus diseases. He described the development of the methods used in Holland and gave details of the organization and techniques used for the large-scale examination of potatoes to test their freedom from virus infection.

Dr. F. O. Holmes (Rockefeller Institute for Medical Research, New York), in a paper on additive resistance to virus diseases in plants, took as his principal example the susceptibility of *Nicotiana* spp. to tobacco mosaic. Plants of *N. glutinosa* can be readily infected, but permit little spread of virus in the tissues and show very low capacity for virus liberation. Crossing *N. glutinosa* with *N. tabacum* gives hypersensitive plants which do not act as sources of infection and so provide a means of controlling mosaic in the field.

Mr. F. C. Bawden (Rothamsted Experimental Station), speaking on the spread and control of plant virus diseases, made the point that the nearest relatives to viruses are normal nuclear proteins. Genetic crosses may conceivably give rise to completely new viruses. In the past fifty years, control measures based on inspection and certification schemes have gone far to free the British potato crop from leaf roll and virus Y. Insecticides have not prevented insect transmission of viruses: what is needed is a 100 per cent effective repellant. Infection by the contact-spread mosaic of tomato can be inhibited by a protectant spray of skim milk. Isolation cannot be considered a trustworthy means of maintaining virus-free stocks of plants until the host range of the relevant viruses is established.

The symposium on "Plant Growth-regulating Substances" opened with a paper by Prof. R. L. Wain (Wye College, University of London) on a new approach to selective weed control. He gave an account of his fundamental investigations on the breakdown of the side-chain of members of homologous series of certain ω-phenoxyalkylcarboxylic acids within plant tissues. He presented chemical, biological and chromatographic evidence showing that β-oxidizing enzyme systems capable of degrading specific acids of this type may be present in the tissues of certain plant species and not in others. From this finding, Prof. Wain developed his new approach to selective weed control based upon enzyme make-up. The results of preliminary experiments along these lines are so promising that it now seems certain that various γ-phenoxybutyric acids, for example, have a part to play in controlling weeds in such crops as celery, parsnip, carrot, clover, lucerne and peas, and have little or no phytotoxic effect.

Dr. W. G. Templeman (Jealott's Hill Research Station), speaking on the uses of plant-growth substances, gave an account of their employment in rooting of cuttings, inhibition of bud-growth, production of parthenocarpic fruits and prevention of fruit-drop. The date of pineapple harvest in Hawaii can now be accurately regulated by a single application of α-naphthylacetic acid to induce flower primordia formation. Dr. Templeman recorded the detailed sequence of the British and the

American discoveries of growth regulators as selective herbicides.

The activity of plant-growth regulators was discussed by Prof. H. Burström (University of Lund). He said that the effects of certain *iso*butyric acids that have been termed anti-auxins might be expected to be the reverse of those of the auxins (β-indoleacetic acid, etc.). However, in certain circumstances these anti-auxins behave like the auxins in increasing cell multiplication, enhancing cell-wall extensibility and, when in high concentrations, inhibiting root-growth. He suggested that the auxins, the herbicides and the anti-auxins all form one group characterized by the ability, present to a varying degree, to induce specific formative effects.

Prof. L. J. Audus and Mr. K. V. Symonds (Bedford College, University of London) reported further studies on the bacterial breakdown of hormone weed-killers in soils. Using a perfusion technique to examine the persistence of 2 : 4-D, they showed that the herbicidal effect of the soil perfusate remains unchanged for twenty days but then disappears completely in 48 hr. An organism of the *Bacterium globiforme* group was isolated and was shown to utilize 2 : 4-D as a carbon source. They suggest that the bacteria during their early period of proliferation gradually convert 2 : 4-D to another phytotoxic intermediate. Meanwhile, the bacteria are producing an adaptive enzyme system which, at the end of the twenty-day lag phase, destroys the intermediate. This hypothesis is supported by chromatographic studies.

The first paper in the symposium entitled "Problems in Applied Zoology" was by Dr. J. Carmichael (Boarded Barns Farm, Ongar, Essex) on insects of veterinary importance and Colonial development. He pointed out that the tsetse fly, because it transmits trypanosomiasis, denies to man and his domestic animals the use of vast areas of potential cattle-country in Africa. Attempts to eradicate tsetse are being made by selective forest clearing and by aircraft application of DDT and BHC, with and without the use of defoliants. The other important group of insects concerned with the development of the livestock industry in the Colonies are ticks, which transmit many serious diseases. Ticks are being controlled by dips containing arsenic, DDT, BHC and toxaphene.

Dr. T. H. C. Taylor (Anti-locust Research Centre) discussed the biological control of insect pests. He emphasized that the control of pests by introduced natural enemies is, at its best, superior to all other methods in cheapness, efficacy and permanence. However, there have been relatively few examples of completely satisfactory control by this method. It has been most successful on tropical islands: it cannot, as a rule, be combined with chemical methods. There is still an urgent need for studies of the biological and other factors causing fluctuations in insect numbers. Our aim should be to acquire the knowledge needed to ensure that the conditions we create for crop production do not unduly favour potentially harmful species.

The address by Prof. J. B. Cragg (University of Durham) on the natural history of sheep blowflies in Britain gave an account of the species responsible for sheep myiasis and discussed their movements and breeding sites. In describing oviposition studies, Prof. Cragg showed that attractants in traps gave different results from those on sheep, and he postulated that sheep wool provides an olfactory stimulus specific for female *Lucilia sericata*. He reviewed the experimental data on the micro-climate of egg masses in fleece.

"Soil-borne Pests and Diseases" were discussed in a parallel session. Dr. S. D. Garrett (University of Cambridge), surveying a century of investigation of root diseases, recorded that the phase of etiology, starting a hundred years ago, continued into the early years of the twentieth century, to be followed by a phase of environmental studies. With the discovery, around 1930, that other micro-organisms are the paramount factor in the environment of a root-disease fungus, the phase of microbial ecology began. Complete epidemiological analysis of a root disease is essential before biological control can be established on a scientific basis, or integrated with other measures of good crop husbandry.

Dr. J. Rishbeth (University of Cambridge) dealt with root diseases in plantations with special reference to tropical crops. He showed that field observations and experimental work with root-infecting fungi have indicated some possible methods of control. Thus, with tea, ring-barking forest trees before felling considerably restricts subsequent damage from *Armillaria mellea* and, with conifers, painting or creosoting stumps directly after felling reduces infection by air-borne spores of *Fomes annosus*. Stump extraction has also proved valuable, especially with rubber.

Dr. J. Doeksen (Netherlands Central Institute of Agricultural Research) spoke on the development in research and control of some important soil-borne pests. He stressed the importance of maintaining the balance of beneficial and noxious insects in the soil and issued a caution against the indiscriminate use of soil insecticides.

The opening contribution to the symposium on "Education and Extension Services in Applied Biology" was by Dr. L. M. J. Kramer (City of London School). Speaking on the subject of the applied biologist, the child and society, he claimed that present school biology contains insufficient ecology to show how applied biology is essential to maintain the contemporary scale of human society. Investigation of examinations, social phenomena and the education of Civil servants and members of Parliament indicates the potentialities of biology. There are sufficient senior pupils to provide the applied biologists needed, and evidence suggests how they may be guided.

Prof. W. Brown (University of London) pointed out that as biological research becomes more and more physiological the need for training in physics and chemistry increases. Pre-university training in biology is desirable to make good citizens, but may be detrimental to the prospective biology specialist if it is given at the expense of chemistry and physics. At the university the student in pure science (botany or zoology) should be given as good an introduction as possible to the applied branches: this can be achieved by vacation work in farming or horticulture. Such experience is particularly valuable for those who would be taking up administrative or advisory work.

Sir William Slater (secretary, Agricultural Research Council) spoke on biological education for agricultural research. This service needs men trained for research in the laboratory and in the field, and the requirements for both are equally high. Agreeing that the undergraduate being trained for biological research must have physics and chemistry as well as biology, Sir William made a plea for a limitation of the mass of facts now to be memorized in university courses—a burden that is smothering enthusiasm and imagination. A mastery of principles and methods should be the aim of undergraduate training, leaving the detailed study of a specialized branch of biology to the early postgraduate years.

Mr. R. Rae, director of the National Agricultural Advisory Service, described the work of that Service. He summarized its organization, gave details of its work and noted some of its principal achievements since its inauguration in 1946.

The symposium on "Crop Protection" began with an address by Dr. Hubert Martin (Science Service Laboratory, London, Ontario). In considering some basic problems in the application of chemistry to crop protection, Dr. Martin pointed out that the subject of insecticides has extended beyond the confines of chemistry and entomology. It now delves deeply into enzymology and electrophysiology. The possibility that toxicants may act on nuclear proteins, thus inducing phenomena comparable to mutations, is of great significance when highly potent crop-protection chemicals are added to the soil.

A paper by Dr. A. E. Dimond and Dr. J. G. Horsfall (Connecticut Agricultural Experiment Station) was entitled "Fifty Years of Fungicides". In the relatively dry summer climate of the United States, the replacement between 1944 and 1950 of Bordeaux mixture by thiocarbamates as potato sprays was followed by a doubling of yield. Future achievements would probably be in internal therapy of plant diseases. The *Fusarium* wilt of carnations is already being controlled commercially in Connecticut by internal therapeutants.

Dr. W. E. Ripper (Pest Control, Ltd.) discussed the development of methods of application for crop protection chemicals. He showed the importance of size of spray droplet and reviewed the existing types of spray machinery and techniques, with special reference to helicopter and aeroplane applications.

Dr. E. Holmes (Technical Department, Plant Protection Ltd.) spoke on the contribution of commerce to plant protection. After giving examples of fundamental chemical and biological studies made by industry and their contributions of new insecticides, fungicides and weed-killers, he dealt with the cost of developing new products and the economic benefits that their use had conferred on agriculture.

"The Forecasting and Assessment of Plant Diseases" formed the subject of the symposium that was opened by Dr. K. Starr Chester (Battelle Memorial Institute, Ohio), who spoke on scientific and economic aspects of the appraisal of losses due to plant disease. He stressed the advantages that would accrue to the agencies and industries serving agriculture if accurate information on losses due to disease were available. He noted the progress made by North America and Western Europe in plant disease surveys and assessments, and described international co-operation in this field now being developed through the Commission on Plant Disease Losses and the World Reporting Service of the Food and Agriculture Organization.

Mr. E. C. Large (Plant Pathology Laboratory, Harpenden), dealing with methods of measurement and forecasting of plant disease in Great Britain, outlined the methods devised for assessing losses due to tulip fire, apple scab, choke of cocksfoot, common scab of potatoes and potato blight. For the last-named he demonstrated the accuracy of present forecasting methods and showed maps giving accurate measures of regional losses from potato blight in England in a dry season (1952) and in the wet season of 1953.

Dr. D. Hille Ris Lambers (Bladluisonderzoek, T.N.O., Netherlands) spoke on potato aphids and virus diseases in the Netherlands. Seed potatoes in Holland must be lifted by a date that is determined each year by the onset of aphis-spread virus infection. The relation of this date to the yearly fluctuations in aphid population was discussed.

A session on "Plant Nematodes" opened with a paper by Dr. B. G. Peters (Rothamsted Experimental Station) entitled "Nematology in Retrospect and Prospect". He showed that the first small nematodes to be described, free-living in the seventeenth century and plant-parasitic in the eighteenth, are identifiable only from their peculiar habitats; taxonomy came relatively late because adequate optical equipment was a prerequisite. In the study of the free-living and plant-parasitic nematodes, the development of two aspects of taxonomy, figure drawing and mensuration, can be traced in the work of five founders, all of whom were living in 1904: Bastian, Bütschli, de Man, Cobb and Goodey. Possible future developments in the identification of species and strains, the investigation of host–parasite relationships and the training of nematologists were briefly discussed.

Mr. F. G. W. Jones (School of Agriculture, Cambridge) spoke on quantitative methods in nematology. He reviewed the techniques of extracting and counting soil nematodes and discussed methods of assessing the errors in laboratory sampling. In field sampling, there is still little information on which to select the best depth, size and number of samples. Mr. Jones described recent developments in assaying the egg contents of eelworm cysts and egg viability. He emphasized the need for further study of nematological techniques to find how time and effort could be saved without loss of accuracy.

The third paper in this symposium was contributed by Dr. P. Bovien (State Plant Pathology Institute, Denmark), who discussed host specificity and resistance to plant nematodes. He considered that there are degrees of resistance, often specific to host variety. The situation is further complicated by the existence of biological races of eelworms, each with a different host-range. Eventually, non-morphological characters may have to be accepted as defining eelworm species.

A conversazione was held on the evening of September 14 in the Main Chemistry Laboratories of the Imperial College. The ninety-five exhibits were grouped into the following twelve sections: growth and soil investigations, plant breeding and crop improvement, methods in applied biology and taxonomy, medical and veterinary zoology, agricultural zoology, forest entomology and ecology, pests of stored products and of timber, horticultural and agricultural entomology, plant pathology and virology, helminthology, chemical methods of plant and animal protection, and apparatus. The attendance at the conversazione, which was not restricted to members of the Conference, exceeded five hundred.

LOW-TEMPERATURE PHYSICS

EACH year at the meeting of the British Association, the increasing specialization of science is deplored and the perennial half-truth that knowledge advances only at the border of subjects is proclaimed. It was refreshing, therefore, that a whole day at the recent meeting at Oxford could be devoted to low-temperature physics, a specialized subject and one of which the frontiers have steadily retreated from their original position on the edge of chemistry.

It was appropriate that this should happen in Oxford, one of the great centres of low-temperature research, and that the four speakers should be drawn from the Clarendon Laboratory.

The first address, by Sir Francis Simon, surveyed the whole of current low-temperature research and explained why the properties of matter at very low temperatures are of such peculiar interest.

As the temperature of a material system is reduced, its state becomes progressively more ordered; thermodynamically, this is described as a decrease in entropy. Order can be increased and entropy decreased not only by a change in temperature but also by other external influences. The simplest case of this is the isothermal compression of a gas. This change of entropy by mechanical or other non-thermal means is the basis of every method of obtaining lower temperatures; and in general, if a substance possesses entropy which can be lowered by compression, magnetization or any other method, then it can be used as the working substance of a cooling process.

Classical thermodynamics, however, was faced with a dilemma, for the law of equipartition of energy predicted that the specific heats of all substances should be finite at absolute zero. Thus their entropies would be undetermined to the extent of an arbitrary infinite quantity, and the concept of an absolute zero lost much of its usefulness. This dilemma was only resolved by the advent of the quantum theory, which predicted that all specific heats would tend rapidly to zero at low enough temperatures as exemplified by Debye's famous T^3 law.

Sir Francis then stressed the fundamental role of the third law of thermodynamics and its corollary the principle of the unattainability of absolute zero in low-temperature research, remarking in passing that the existence of substances with frozen-in entropy does not constitute a true exception since these are not in equilibrium states.

Sir Francis traced the progressive stages by which entropy is removed as a substance is cooled. First the gas liquefies, then the liquid solidifies. The entropy of the solid will be largely due to lattice vibrations, although in certain substances free rotation of the molecules in the crystal may contribute. In non-magnetic substances the entropy due to all these causes will be almost completely removed at 1° K. In certain magnetic substances, however, the entropy associated with the disordered orientations of the elementary magnetic moments will persist to very much lower temperatures of the order of a few thousandths of a degree. Since this entropy can be influenced isothermally by a magnetic field, this can be made the basis of a method of cooling.

This method of isothermal magnetization and adiabatic demagnetization, first employed by Giauque in 1933, has now been successfully used in a great many laboratories. The lowest temperature attainable by this method is determined by the strength of the interactions between the atomic magnetic moments which are responsible for the ordering of the magnetic system at the lowest temperatures. By a choice of suitable substances in which this interaction is weak, temperatures of the order of 0·001° K. have been reached both at Leyden and Oxford.

Apart from the entropy associated with the atomic moments in paramagnetic substances, there is also the entropy associated with the nuclear magnetic moments. Since the magnitude of these moments is some thousand times smaller, their interactions are very much weaker and it is to be expected that the nuclear entropy will persist to very much lower temperatures—of the order of one-millionth of a degree. In order to make use of nuclear magnetic moments in a cooling process, it is necessary to be able to influence their entropy by the application of a magnetic field. Very large fields of the order of 100 kilogauss applied at very low temperatures of the order of 0·01° K. will be needed. The technical problems this poses have not as yet been surmounted.

Sir Francis Simon concluded by showing how these experiments throw new light on the concept of temperature itself. The naïve association of temperature with kinetic energy clearly becomes untenable when, for example, we consider a 1-mm. cube of diamond at 0·01° K. which contains on the average only one quantum of thermal energy. The concept of temperature is, in fact, inextricably linked with those of order and entropy. A substance which has lost all its entropy is effectively at absolute zero. The temperatures reached by adiabatic demagnetization are perhaps unique in the whole universe. In interstellar space, matter exists at low temperatures but also at very low densities, so that its entropy is large. In stars, on the other hand, while the density is high so is the temperature, and the entropy is again large. It is only in the laboratory that condensed matter at very low temperatures is found.

Sir Francis Simon's introduction was followed by Dr. K. Mendelssohn, who dealt in a picturesque and vivid way with the properties of superconductors and liquid helium, which he tentatively described as a new state of aggregation.

Since the discovery by Kamerlingh Onnes that the electrical resistance of pure mercury vanishes at temperatures below 4° K., a great many other elements, mainly those in Groups IV*a* and V*a* and II*b*, III*b* and IV*b* of the Periodic Table, have been shown to be superconducting. The resistance has been found to be not only small but, in fact, effectively zero, as evidenced by the possibility of obtaining persisting currents in rings of superconductors which showed no diminution in their intensity after periods as long as a week. An empirical law relating the occurrence of superconductivity to the atomic volume of the element has been traced, and this has led to the production of superconducting alloys between two non-superconducting elements, one having too large, the other too small, an atomic volume. These alloys are, in many ways, analogous to the ferromagnetic Heusler alloys.

No completely satisfactory theory of superconductivity exists, although the phenomenological theory, mainly due to the late F. London, has done much to clarify the experimental facts. Superconductivity is a function of the metallic free electrons, and the existence of a specific heat anomaly at the superconductive transition temperature indicates that the entropy of, at any rate, part of the free electrons is considerably reduced in the superconductive state. They may, therefore, be considered to exist in an ordered state the nature of which is unlike anything we would normally consider to be ordered since they are still free to take part in electrical conduction. Superconductivity has as yet found no practical application, although extremely sensitive bolometers have been made using superconductive elements. A photograph of Prof. D. H. Andrews, of Johns Hopkins University, taken by his own infra-red radiation using a superconductive bolometer as the sensitive element, was shown; its relation to a conventional photograph was as that of a Paul Klee to a Vermeer.

Liquid helium also exhibits behaviour in many ways analogous to superconductivity. At 2·2° there is a discontinuity in the specific heat, the coefficient of thermal expansion and the thermal conductivity. The latter is most strikingly shown when helium is cooled by evaporation. As the temperature is reduced below 2·2°, all bubbling ceases and the liquid becomes perfectly still. This is because the thermal conductivity increases more than a millionfold at the transition temperature. The viscosity of liquid helium measured with an oscillating disk shows no marked discontinuity; yet if an attempt is made to measure the viscosity by studying flow through a fine capillary, it is found that the flow is independent of the pressure head and the apparent viscosity is less than that of any gas, let alone liquid. These phenomena by no means exhaust the peculiarities of liquid helium, and Dr. Mendelssohn went on to describe and illustrate the fountain effect, the mechanocaloric effect and the existence of film-flow, which he likened to the emission of α-particles from nuclei.

In all these ways helium exhibits a similarity to superconductors, for in both cases the underlying phenomenon is transport without friction. Moreover, there is a striking resemblance between the entropy – temperature curves for both classes of substance. This suggests that in both cases the transition from the normal to the superfluid state is associated with the same type of increase of order. Since helium below the λ-point is a liquid, this cannot be spatial order but may rather be pictured as order in momentum-space. This, although not a particularly simple idea, might be visualized by considering the order introduced into traffic moving along a road by the introduction of a speed limit: in the absence of the limit the relative positions of vehicles change with time; after the introduction of the limit, they all move with the maximum permissible velocity, and although the scenery past which they move changes, their relative positions remain the same.

At present there is no complete theory of liquid helium, although the fact that the odd isotope helium-3 does not show superfluidity indicates that part of the explanation of the superfluid behaviour of liquid helium-4 must be that it obeys Bose–Einstein statistics.

Dr. Mendelssohn concluded his address by some remarks of a more speculative nature. Perhaps the cold stars might be regions in which matter exists in the superfluid state, and since we have in superfluidity a new state of matter, may there not be yet another state of matter appropriate to living organisms?

The concluding part of the morning's proceedings was opened by Dr. A. H. Cooke, who described how paramagnetic resonance and relaxation measurements contribute information of great value to low-temperature research.

Prior to the Second World War, most of our knowledge of paramagnetism came from the measurement of the static magnetic susceptibility. The susceptibility is, however, only an average effect due to all the paramagnetic constituents of the substance. Since in even the simplest substances containing only one paramagnetic element the different atoms are often subjected to different internal fields, resulting in a difference in their contributions to the susceptibility, the interpretation of susceptibility measurements in terms of the magnetic properties of individual atoms was an undertaking of considerable difficulty. The method of paramagnetic resonance, on the other hand, studies the properties of each group of atoms separately and makes it possible to give an unambiguous theoretical interpretation of the paramagnetism.

The principle of the method was illustrated using a small gyroscope. When a magnetic field is applied to a magnetic ion, it precesses about the direction of the magnetic field at a frequency which depends on the strength of the field and the ratio of the magnetic and angular momenta of the ion. If an oscillatory magnetic field is applied at right angles to the steady field, the ion will make transitions, from one orientation to another, which absorb energy from the oscillatory field. This absorption can be detected, and thus a measurement of the field and frequency at which absorption occurs allows the determination of the ratio of magnetic to angular momentum. Since the latter is usually known from other evidence and is in any event an integral multiple of $\frac{1}{2}\hbar$, the measurement determines the magnetic moment.

In the demonstration the gyroscope represented the paramagnetic ion, and the magnetic field was applied by means of a length of elastic. When an oscillatory elastic field was applied at right angles, most convincing transitions from one orientation of the gyroscope to another were produced.

Knowing the magnetic moments of the paramagnetic ions in a substance makes it possible to predict many of its magnetic and thermal properties. Paramagnetic resonance experiments, however, give information only indirectly about the strength of the interaction between the magnetic ions, and it is these interactions which determine the behaviour of the substance at the lowest temperatures.

Due to these interactions, there is a contribution C_M to the specific heat which is proportional to $1/T^2$ and is therefore negligible except at low temperatures, where it rapidly assumes a dominant role. For many substances C_M is of the same order as the lattice specific heat at temperatures of a few degrees. Paramagnetic relaxation experiments enable us to determine this magnetic specific heat independently of other contributions to the specific heat.

When a system of spins is magnetized, heat of magnetization is generated, and this has to be lost by the spin system to its surroundings, that is, the crystal lattice. At high temperatures the heat of magnetization is small and the contact between the spin system and the lattice is good, so that this is a very rapid process. At temperatures below 20° K., however, this transfer may take an appreciable time; thus after the field is put on, it may take a fraction of a second for the spin system to lose its heat of magnetization and attain its equilibrium magnetization. Therefore, if the susceptibility is measured using a rapidly oscillating magnetic field, the quantity observed will be the adiabatic susceptibility of the spin system. A measurement with a static or slowly varying field will yield the isothermal susceptibility. From these two quantities a simple thermodynamic relation leads directly to the magnetic specific heat.

Thus the method of paramagnetic relaxation complements the resonance experiments. Since the magnetic specific heat is a measure of the strength of the interaction between the magnetic ions, and this determines the lowest temperature available in adiabatic demagnetization, relaxation measurements give a useful guide to the choice of substances for demagnetization. For example, iron ammonium alum, with $CT^2/R = 0{\cdot}014$, needs at 1° K. the application of 30 kilogauss to reduce its temperature to 0·01° K., whereas cerium magnesium nitrate, with $CT^2/R = 7{\cdot}5 \times 10^{-6}$, reaches 0·003° K. from a field of 15 kilogauss.

The final paper was given by Dr. N. Kurti and dealt with the low-temperature aspects of nuclear orientation.

The object of this address was the description of methods that have been, or could be, used for orienting atomic nuclei in solids. Normally the elementary nuclear magnets point at random in all directions. Under favourable conditions and at very low temperatures, it is possible to establish preferential orientations with respect either to an external magnetic field or to a crystal axis.

Nuclear orientation was originally conceived as a possible method of producing temperatures of the order of one-hundred-thousandth or one-millionth of a degree absolute. The lowest temperature that can be obtained by means of the adiabatic demagnetization of paramagnetic substances (in which the electron spins are the elementary magnets) is of the order of a few thousandths of a degree. This lowest temperature is determined by the magnitude of the interaction forces between the electronic elementary magnets. With nuclei, which have a thousand times smaller magnetic moments, one could expect to reach much lower temperatures because the interaction forces are smaller. In order to carry out such a nuclear demagnetization experiment, the nuclear paramagnetic substance (say, a metal the nuclei of which possess magnetic moments) has first to be magnetized in a field of between 50 and 100 kilogauss at 0·01° K. This presents great difficulties, and no successful nuclear magnetic cooling has been carried out as yet.

At 0·01° K. and in a field of 100 kilogauss, the nuclei would be directed preferentially along the magnetic field. Such oriented nuclear systems can be of great use to nuclear physics. If we have a radioactive substance which emits γ-rays, then, even if the intensity of emission from one individual nucleus is anisotropic, the total radiation emitted from a piece of material will be isotropic in ordinary circumstances because of the random distribution of the nuclear axes. The behaviour of an assembly of oriented nuclei, however, would approximate more and more to that of an individual nucleus. Details of the importance of such experiments were given in Dr. Grace's paper later in the session.

If one wants to produce oriented nuclei for radioactive experiments, some experimentally simpler methods are also available. Instead of using an external magnetic field of 100,000 gauss, one can make use, in suitable cases, of the strong magnetic fields (of the order of half a million gauss) which the electron spin produces at the nucleus in paramagnetic ions. In such cases the nuclear spin sets itself parallel to this local magnetic field if the temperature is low enough (a few hundredths of a degree absolute). If, moreover, the electron spins which are responsible for these local fields are oriented parallel throughout the specimen, a high degree of nuclear orientation will result. The ordering of the electron spins is brought about either by the action of the electric field of the crystal lattice or by a relatively modest external magnetic field of the order of 1 kilogauss.

The former method was used in the first conclusive demonstration of nuclear orientation in an experiment carried out by Drs. Daniels, Grace and F. N. H. Robinson in September 1951 at the Clarendon Laboratory in Oxford. The anisotropy of the γ-rays emitted by radioactive cobalt-60 which was incorporated in a paramagnetic crystal and cooled to one-hundredth of a degree was clearly shown. Since then many more experiments have been carried out with both methods in Oxford and elsewhere, and in one of the Oxford experiments a degree of orientation of nuclei of more than 90 per cent was attained.

Although at present most of these experiments yield results of main interest to nuclear physicists, the situation will undoubtedly change when nuclear magnetic cooling experiments get under way and, possibly, temperatures of 10^{-5} or 10^{-6} degrees will be reached. It has been suggested, for example, that at these temperatures one might observe 'nuclear ferromagnetism'.

Dr. Kurti concluded by asking whether it is wise and indeed justified to classify these results according to whether they belong to nuclear physics or to low-temperature physics. It is more important, he said, to realize that they are the outcome of a combination of two fundamentally different and distant branches of physics.' F. N. H. ROBINSON

OBITUARIES

Prof. F. Wood Jones, F.R.S.

WITH the death of Dr. Frederic Wood Jones at the age of seventy-five on September 29, there passed an anatomist who was well known not only for his numerous contributions to human and comparative anatomy and anthropology, but also for his unusual versatility (his interests extended far beyond the confines of pure morphology) and his vigorous expositions of Lamarckian and teleological conceptions.

Wood Jones was born in London on January 23, 1879, studied medicine at the London Hospital, and graduated in 1903. During 1905–7 he was stationed on one of the Cocos-Keeling Islands as a medical officer of the Eastern Telegraph Co., and it was here that his scientific career may be said to have derived its initial inspiration. For, as he relates, his medical duties were so nominal as to allow him to spend much of his time exploring coral reefs and making observations on the local fauna. In 1910 he published a book on "Coral and Atolls" in which he ventured an original interpretation of atoll development, an interpretation which, even if it did not gain general acceptance, aroused considerable interest because of its very novelty. It was as a result of these studies that he was awarded the degree of D.Sc. of the University of London.

In 1907 he joined the late Sir Grafton Elliot Smith in anthropological studies on behalf of the Egyptian

Archæological Survey of Nubia, and in 1909 he was appointed lecturer in anatomy in the University of Manchester. His subsequent academic career was varied as well as distinguished, for he occupied chairs successively in the Universities of London, Adelaide, Hawaii, Melbourne, Manchester and the Royal College of Surgeons, and also (for one year) acted as director of anatomy at the Pekin Union Medical College.

A man of many and varied experiences, Wood Jones was imbued with a restless curiosity which found expression in several books of essays on a great diversity of subjects. His pleasing literary style and descriptive powers, combined with a certain originality of approach, made his writings singularly attractive and stimulating; this was particularly so with his lighter essays, but it was also true of his more serious expositions, even though the intrusion here and there of his personal prejudices against some of the well-established principles of evolution occasionally proved exasperating to those who allowed themselves to be too easily exasperated by such expressions of 'unorthodoxy'. In one of his earliest books, "Arboreal Man", published in 1916, Wood Jones elaborated in a series of anatomical essays the thesis (which he continued to emphasize in many of his later works) that, compared with other Primates, man is fundamentally primitive in many details of his anatomical structure. Indeed, it was this general conception which led him to suppose that man has occupied a rather unique position in the evolutionary series, for he argued that the retention of these primitive features could only be explained on the basis of a very prolonged period of evolutionary independence. In a more comprehensive work on "Man's Place among the Mammals", published in 1929, he further elaborated these ideas, contending with considerable dialectical skill that man's relationship to other Primates is far more remote than is suggested by the evidence of comparative anatomy and palæontology. It is fair to say that, although the more extreme views put forward by Wood Jones made but little impact on biological thought, he certainly provoked his contemporaries by the very persuasiveness of his literary style to give more critical attention to the validity of the evidence on which he relied.

Apart from his essays and books, Wood Jones's most important contributions to anatomy are embodied in numerous papers which have appeared from time to time in the *Journal of Anatomy*, the *Proceedings of the Zoological Society*, and elsewhere, and which consist mainly of descriptive studies in the field of comparative anatomy. But he also made important contributions in the allied fields of embryology, physical anthropology and palæontology. All these papers are characterized by a refreshing originality and by illuminating interpretations of the relationship between structure and function. His most systematic study (and in some ways one of his best works) was his comprehensive survey of the mammals of South Australia, published in the series of handbooks issued during 1923–25 by the South Australian Branch of the British Science Guild. Like all his published works, these are illustrated entirely by his own drawings, which display particularly well the unusual skill and attractive style of his draughtsmanship. In his two books on human anatomy, "The Principles of Anatomy as seen in the Hand", first published in 1920, and "Structure and Function as seen in the Foot", published in 1944, Wood Jones showed a profound knowledge of topographical and morphological detail, and at the same time gave abundant evidence of the exceptional powers of observation which enabled him to contribute so much original information beyond the scope of the standard text-books of anatomy. They also display his intimate acquaintance with the history and literature of anatomical discovery, for he makes constant reference in them to observations of the older anatomists which seem too often to have been forgotten.

In temperament, as well as in his scientific work, Wood Jones was an individualist, and he was sometimes impatient of new orientations in anatomical teaching and research. But it would be difficult to over-estimate the service which he has done to his subject by his insistence on the comparative and functional approach to anatomical studies, by the cumulative importance of his many original observations, and by the inspiration which he gave to his contemporaries and his students through his lectures and essays.

Prof. Wood Jones is survived by his widow, Gertrude Clunies, daughter of the late George Clunies-Ross, governor of the Cocos-Keeling Islands.

W. E. LE GROS CLARK

Sir Roderic Hill, K.C.B.

SIR RODERIC HILL, rector of the Imperial College of Science and Technology, London, died on October 6 at the age of sixty.

In 1948, the Governing Body of the Imperial College appointed a committee to select a new rector, and also invited representative members of the academic staff to consult among themselves and make suggestions. The result was unexpected: both groups independently suggested Air-Chief Marshal Sir Roderic Hill. Seldom can an appointment have been so acceptable to all concerned or have proved so happy in its outcome.

From the moment he took office, it was clear that the new rector would prove a powerful leader, and that his personality and example would stimulate those who came in contact with him to give of their best to the College. A humanist by education, he had, during his long career in the R.A.F., showed judgment and experience in technological matters which many professional engineers and scientists might well have envied, and the appreciation by his colleagues that he possessed such ability lent added weight to his view, so often expressed, that the education of technologists must be broadened if they were to exercise their functions with a full sense of responsibility. His concern with this aspect of education led him to initiate general lunch-hour lectures twice a week throughout the session, covering a wide range of subjects, a particular example being the encouragement of College musical activities by the appointment of a distinguished musician as special lecturer and adviser.

The general scheme, of which this was part, was given the title 'Touchstone', which will remain one of many reminders of the ideals of its originator. Under this scheme, also, week-end study circles were held at Silwood Park, the College Field Station near Ascot, at which students, members of the staff, and experts from outside the College met to discuss social and political questions of the day.

While this and much more was being developed, Hill carried a heavy burden in connexion with the projected expansion of the Imperial College at the behest of the Government. The opportunities thus presented appealed to his imagination and he threw himself into planning and directing with that energy which he always gave so lavishly.

It was a great joy to him when, in 1953, he was elected vice-chancellor of the University of London, a post which his father, Prof. M. J. M. Hill, had held many years earlier. Some of his friends feared that the responsibilities of this post added to those he already carried might prove too great a strain and, in fact, his health obliged him to resign the vice-chancellorship before the completion of his year of office.

His career before he joined the Imperial College will be recorded elsewhere, and it is only possible to say here that the ability, enthusiasm, capacity for hard work, and keenness in everything he did, which produced an outstandingly distinguished R.A.F. officer, were all brought to the service of the College and the University. All these qualities and one other, which will be remembered most by all of us, that of charming friendliness, combined to give the College a rector who will always be remembered with deep affection. A. J. Sutton Pippard

Prof. Carl I. Cori

The death occurred in Vienna on August 31 of Carl I. Cori, emeritus professor of zoology in the German University of Prague. Born almost ninety years ago in Brux, Bohemia, he studied zoology and medicine at the ancient German University of Prague and after graduation became assistant and lecturer at the Zoological Institute under Hatschek. In 1898 he was made a professor and director of the Zoological Station of Trieste, where up to 1914 he organized biological and marine research. Pupils from many countries came to his station, and the cruises of the research vessel *Adria* which Cori himself had helped to design, and of which he was the master, are still remembered by many biologists. After the First World War, which he spent in charge of a malaria unit, he found his station closed down and he returned to Prague, where in 1919 he became professor of zoology. Three times elected rector of the German University, he retired in 1936 and had lived in Vienna since 1946.

Cori's most important publications concerned the Phoronids and Bryozoa. The chapters in Bronn's "Klassen und Ordnungen" referring to these two groups, as well as to the Brachiopoda and Entoprocta, were also written by him. Further important papers dealt with segment formation in annelids and vertebrates, the circulatory system of *Ammocoetes* and with the fauna of the Adriatic. Cori also contributed in many ways to marine and limnological research techniques. Of several books, one, "The Naturalist's Introduction to the Adriatic Littoral", appeared in several editions.

Prof. Cori is survived by a son, the well-known biochemist, C. F. Cori, of St. Louis, Nobel Laureate in 1947 for medicine, and by two daughters, one of whom is married to the Viennese geneticist, F. Mainx

The institutions at which Cori was prominently working have been destroyed by two world wars but his teaching and personality will be remembered by his pupils in many countries. H. Kalmus

NEWS and VIEWS

European Organization for Nuclear Research

President of Council : Sir Ben Lockspeiser, K.C.B., F.R.S.

At the first session of the European Organization for Nuclear Research, held in Geneva on October 7, Sir Ben Lockspeiser, secretary of the Department of Scientific and Industrial Research in Great Britain, was elected president of the Council of the Organization, in succession to M. Robert Valeur. M. Valeur, who has been director of the Interim Council of the Organization since 1953, is a member of the French Diplomatic Service and has recently been appointed director of the Information and Cultural Services of the French Embassy in Washington. Sir Ben has from the beginning taken an active part in the work of the Interim Council of the Organization as a delegate of the United Kingdom and as chairman of the interim finance committee since 1953. After holding successively a number of key appointments in Britain in the field of aeronautical research, he became chief scientist to the Ministry of Supply in 1946, and, in 1949, secretary to the Department of Scientific and Industrial Research (see *Nature*, 163, 314; 1949). He thus brings to his new post a wealth of experience both as a research worker and administrator.

Deputy Director-General : Prof. E. Amaldi

The new deputy-director-general of the European Organization for Nuclear Research is Prof. Edoardo Amaldi, who was born in Piacenza in 1908. He has spent much of his time working at various laboratories throughout the world. Though he has studied the spectroscopy of atoms and molecules, his main work has been devoted to nuclear physics, particularly the diffusion and absorption of neutrons and the radioactivity induced by neutrons; in collaboration with Enrico Fermi he published a study of slow neutrons which has proved to be of fundamental importance for research in this whole field. During the past few years he has worked mainly on cosmic rays, especially the properties of mesons of high energy, the tau and kappa mesons and hyperons. He became professo of experimental physics in the University of Rome in 1937, director of the Institute of Physics in 1950, and is a member of the Accademia Nazionale dei Lincei. Prof. Amaldi is one of the pioneers of the European Organization for Nuclear Research. A secretary-general of the Organization since its creation in 1952, he has been responsible to the Council fo the work of the Executive Group, which prepares the plans and the budget for the future. The energ with which he has applied himself in the service o the Organization has been an important factor in it growth to a fully fledged body.

Director : Prof. F. Bloch

The post of director of the European Organization for Nuclear Research has been filled by Prof. Féli Bloch, who took up his duties on October 1, on leav of absence from Stanford University, California. Pro Bloch was born in Zurich in 1905 and started h university career there as a student of engineering at the Eidgenössische Technische Hochschule. Very soon however, partly inspired by Schrödinger's lectures, he changed over to theoretical physics, and in 1927 moved to Leipzig, where as a pupil of Heisenberg he was awarded his doctorate for a dissertation on the quantum mechanics of conduction electrons. After working successively under Pauli, Heisenberg, Bohr and Fermi, he went to Stanford in 1934 as associate professor of physics, where in 1939, in collaboration with Alvarez, he made the first measurement of the magnetic moment of the neutron, using the cyclotron at Berkeley. In 1946 Prof. Bloch published the theory and, together with a number of collaborators, the experimental technique of measuring very accurately nuclear magnetic moments by the method of 'nuclear induction'. For this he was awarded the Nobel Prize for Physics in 1952 jointly with Prof. E. M. Purcell, who had done independent work in the same field (see *Nature*, 170, 911; 1952).

Director of the Synchro-cyclotron Division : Prof. C. J. Bakker

PROF. CORNELIS JAN BAKKER has been appointed a member of the Directorate and director of the Synchro-cyclotron Division. Prof. Bakker was born in 1904 and studied physics under Zeeman in Amsterdam, taking his doctorate in 1931 for work on the Zeeman effect in the spectra of the noble gases. After this he spent a year in London at the Imperial College of Science and Technology continuing his work in the field of spectroscopy. He then joined the scientific staff of Philips at Eindhoven, where he did research on certain physical problems in relation to radio. However, his interests turned to nuclear physics and during the Second World War, in collaboration with Prof. Heyn, he started designing a cyclotron for Philips. In 1946 he succeeded Gorter as professor of physics and director of the Zeeman Laboratory of the University of Amsterdam and also became director of the Institute of Nuclear Physics, the focal point of Dutch nuclear research, sponsored by Fundamenteel Onderzoek der Materie (F.O.M.), by the city of Amsterdam and by Philips. There he and his team of assistants work with the cyclotron which was designed and built by him for Philips. Prof. Bakker is a member of the Dutch Reactor Committee and, as such, a member of the Joint Dutch–Norwegian Committee, which operates the joint reactor at Kjeller in Norway; he is also secretary of the Joint Committee on Spectroscopy of the International Union of Pure and Applied Physics and the International Astronomical Union. He was one of the original eight experts invited in 1951 to draw up plans for the future of the European Organization for Nuclear Research, and since 1952 he has been director of the Synchro-cyclotron Group; with about fifteen staff members and consultants he has been carrying out the engineering studies on the synchro-cyclotron. The new Division has begun moving to Geneva, but at the moment Prof. Bakker is only spending part of his time with it.

College of Aeronautics : Prof. J. A. J. Bennett

THE Board of Governors of the College of Aeronautics has appointed Dr. J. A. J. Bennett to be professor of aerodynamics in succession to Prof. A. D. Young, who has taken the chair of aeronautical engineering at Queen Mary College, University of London (see *Nature*, January 9, p. 64). Prof. Bennett, who holds the degree of D.Sc. of the University of Glasgow and the diploma of the Imperial College of Science and Technology, London, is an international authority in the field of helicopters. He has been a member of the Helicopter Committee of the Aeronautical Research Council since 1945 and has served on a number of British missions devoted to rotary-winged aircraft. He was the originator of the Gyrodyne, which established an international speed record in 1948. A very considerable number of papers on rotary-winged aircraft have appeared under his name in technical journals both in Great Britain and abroad. Prof. Bennett is a founder member of the Helicopter Association and a member of the Council, and a founder member of the American Helicopter Society. For the past two years he has been engaged on helicopter research at Hiller Helicopters, California, and, prior to this, he was for seven years head of the Helicopter Branch of Fairey Aviation Co., Ltd.

H. W. B. Roozeboom (1854–1907)

HENDRIK WILLEM BAKHUIS ROOZEBOOM, who is remembered in the history of physical chemistry for having demonstrated the industrial importance of the phase rule, was born in the historic town of Alkmaar on the North Holland Canal, a century ago, on October 24, 1854. His interest in chemistry began in his school-days; but he was too poor to go to a university. In 1875 he was offered a position as assistant analyst by J. M. van Bemmelen, and three years later he became an assistant in the chemical laboratory of the University of Leyden. He obtained the Ph.D. of this university in 1884, and in 1890 was appointed lecturer in chemistry. In 1896 he succeeded J. H. van 't Hoff in the chair of inorganic and physical chemistry in the University of Amsterdam. In 1875 the American physicist, Josiah Willard Gibbs, contributed to the *Transactions of the Connecticut Academy* his classic "On the Equilibrium of Heterogeneous Substances", which established the phase rule for chemical equilibrium and change. Roozeboom made careful studies of melting points and solubilities, while investigating the equilibria between solid and liquid phases in various systems, and in 1904 began publication of "Die heterogene Gleichgewichte vom Standpunkt der Phasenlehre". Completed in 1918, after his death, by his pupils, this work, particularly on the composition of the salt hydrates, showed the practical value of Gibbs's rule. Roozeboom died on February 8, 1907, at the age of fifty-three.

Scientific Instruments from the Thirteenth to the Nineteenth Century

ASTROLABES, armillary spheres, portable sundials and other antique scientific instruments constitute a valuable source for the historian of science. They afford evidence which is complementary to the printed and manuscript material, and they may provide information unobtainable in any other way. Besides all this, they are frequently beautiful objects in themselves—products of a happy marriage of scientific design and the art of the metal-worker and engraver. The most important private collection of such instruments, that of Mr. J. A. Billmeier, of London, is described in the October issue of *The Connoisseur* by Dr. C. H. Josten, curator of the Museum of the History of Science, Oxford. The greater part of the collection was recently acquired from M. Henri Michel, of Brussels, well known for many years as a leading authority and connoisseur in this field. The 153 choice instruments which have now come to Britain, together with the museum collections at South Kensington, the National Maritime Museum, the British Museum, the Whipple Museum at Cambridge and the Museum of the History of Science at Oxford, constitute a tremendous national heritage. Nowhere else in the world is such an aggregate of fine collections available for study. Dr. Josten's article is well illustrated with photographs of many of the instruments, including six of the twenty-one astrolabes and an interesting selection of sundials. A fuller account has been given in a printed Catalogue of the Billmeier Collection, which was exhibited in May 1954 by Messrs. Frank Partridge and Sons, London.

Mycorrhizal Uptake and Translocation of Phosphorus

In investigations of the uptake of phosphate by excised mycorrhizal roots of the beech, J. L. Harley and J. K. Brierley have obtained evidence of the active transport of this nutrient from the fungal sheath into the host tissue (*New Phytol.*, 53, 2, 240; 1954). They point out that movement of substances from the external solution might be by way of the inter-hyphal spaces, or the walls of the fungal tissue, or through the living hyphæ themselves. In critical experiments, excised mycorrhizal roots were allowed to absorb radioactive phosphorus during the first phase while, during the second phase, the distribution of the radioactive phosphorus in the fungal and host tissue was determined after known time periods under conditions in which the rate of metabolism was varied. The rate of movement of phosphorus-32 from fungus to host was at first rapid, but became slower after 10–15 hr.; it was sensitive to temperature and oxygen supply. In low oxygen concentrations and in anaerobic conditions especially, phosphorus-32 was lost from the roots into the washing solution at normal temperatures. No such losses occurred at low temperatures in either aerobic or anaerobic conditions nor at normal temperatures in air. The loss of phosphorus-32 from roots in anaerobic conditions was entirely from the fungal tissue and resulted from a process which had a high temperature coefficient. In roots which had been returned to normal temperatures after a period of washing at low temperatures or returned to aerobic conditions after a period of washing in anaerobic conditions, transport of phosphorus from fungus to host, temporarily prevented, was resumed at an undiminished rate. The authors conclude that active transport of phosphorus from fungus to host occurs in mycorrhizal beech roots. The mechanism of transport is dependent upon aerobic metabolic processes in the fungal tissue as well as upon the absorptive processes of the core. The phosphate which is lost from roots kept in low oxygen concentrations is entirely released from the sheath and results from temperature-sensitive anaerobic processes occurring in that tissue. (See also *Nature*, October 9, p. 684.)

Abnormal Plant Growth

The Brookhaven National Laboratory, Upton, New York, has rendered a useful service to botany by bringing together a number of leading research workers interested in the phenomena of abnormal and pathological plant growths and their causation ("Abnormal and Pathological Plant Growth", Brookhaven Symposia in Biology No. 6; pp. 303, Office of Technical Services, Dept. of Commerce, Washington 25, D.C., 1954; 2.10 dollars). While the subject itself is not new, it is evident from a reading of this report that the application of recent and new techniques has resulted in the acquisition of many new and interesting facts and in a persistent analytical approach to the underlying causation of the several manifestations of abnormal growth. The symposium covers a wide field, and abnormal growth developments induced by physical, chemical and biological agents are described and discussed with special reference to their genetical, physiological and morphological aspects. In this diverse assemblage of new information the reader may read at large or he may read selectively, paying special attention to such major topics as differentiation and organogenesis, tissue culture and tumour formation as induced by genetical, bacterial, virus or insect agencies. Some of the investigations are reported in considerable detail, special reference being made to the method of induction of the abnormal development and to the related nutritional aspects. The substance of the discussion on each of the papers is also given.

Notes on Nuclear Science

A set of notes on nuclear science, mainly factual and explanatory, providing reliable data and references suitable for lecturers and teachers has been compiled by the Atomic Sciences Committee of the Association of Scientific Workers. The notes, which are in loose-leaf form, are in three sections, of which Vols. 1 and 2, dealing with scientific and industrial aspects, and the military aspect, respectively, have recently been issued; and Vol. 3, on international control, is to be issued shortly. In order to keep the notes up to date, it is intended to issue annual supplements to the respective volumes as the necessity arises. Vol. 1 is of a general nature and summarizes the basic elements of nuclear science, the large-scale release of nuclear energy, nuclear energy programmes in different countries and the production and uses of radioactive and stable isotopes. Vol. 2 deals with the effects of atomic weapons, in particular with the physical and biological effects of the bombs dropped on Japan in 1945, and with the problem of civi defence. A very detailed bibliography is a feature of this volume, and an addendum brings the information and data, on thermonuclear bombs, for example up to the date of publication, September 1953.

South African Museum: Report for 1953–4

The report of the South African Museum, Cape Town, for the year ended March 31, 1954 (from the Museum; pp. 28), records that, with the prospective legislation repealing the South African Museum Act of 1857 and the proposal to include museums and other organizations as State-aided institutions, it is hoped that the future of the South African Museum will be as progressive as it has been in the past. A preliminary survey of the site for the extension of the east wing has been made, and the trustees hope for the erection of this long-deferred addition. It is intended that it shall provide extra space for the larger mammals and also for historical objects. In Britain all strandings of whales are immediately reported by the coastguards to the British Museum (Natural History). Unfortunately, in South Africa there are long stretches of coast where such occurrences are never seen or reported, and the Museum is taking active steps to remedy this position Research is now considered to be a major functio of museum staffs, and the impressive list of publications, including those in the *Annals of the South African Museum*, bears witness to extensive activity in this direction.

Radiation Hazards in Industry: Conference in London

THE third conference of the British Occupational Hygiene Society will be a one-day meeting on "Radiation Hazards in Industry", to be held in the London School of Hygiene and Tropical Medicine on November 1. The conference is open to non-members (on payment of a fee of one guinea) as well as to members of the Society. The chair will be taken by the president of the Society, Prof. E. J. King, professor of chemical pathology in the Postgraduate Medical School, University of London. Four papers will be presented as follows: the health of workers exposed to ionizing radiation, by A. S. McLean, principal medical officer, Department of Atomic Energy; radiation safety in the Industrial Group of the Department of Atomic Energy, by D. R. R. Fair, head of the Health Physics Division, Department of Atomic Energy, Windscale Works, Sellafield; protection against X-rays and gamma-rays in the industrial field, by W. Binks, Radiological Protection Service, Ministry of Health and Medical Research Council; and safety criteria in atomic energy, by F. R. Farmer, assistant director (production), Department of Atomic Energy, Industrial Group Headquarters, Risley. There will be a short discussion after each paper. The conference will be reported, in due course, in the *British Journal of Industrial Medicine*. Those intending to be present should complete and return by October 25 the appropriate form, obtainable from the honorary treasurer, Mr. D. E. Hickish, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

Biology and a General University Education

A RESIDENTIAL conference is being arranged by the Institute of Biology in co-operation with members of the staff of the University College of North Staffordshire on the place of biology in a general university education. The meeting will take place at the University College of North Staffordshire during December 19–21. Part of the programme will revolve around the place of biology in a general science course at university-level, while the remainder of the programme will be concerned with the place of biology in a university education which is not primarily scientific. Among those expected to take part will be Dr. J. Hutchins, professor of physiology in the University of Chicago, who has been closely concerned with the planning and teaching of a course in biology for arts students, Prof. S. Zuckerman, Prof. A. R. Gemmell, Dr. C. Gordon, Mr. L. J. F. Brimble, Mr. W. B. Yapp, Prof. J. F. Danielli, Prof. T. A. Bennet-Clark and Prof. F. W. Rogers Brambell. Further information can be obtained from the Secretary, Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1.

Fourteenth International Congress of Pure and Applied Chemistry, Zurich

THE dates of the Fourteenth International Congress of Pure and Applied Chemistry and the Eighteenth Conference of the International Union of Pure and Applied Chemistry, both of which will be held in Zurich, are July 21–27 and July 20–28, 1955, respectively (and not the other way round, as given in *Nature* of September 25, p. 588). Papers will be limited to twenty minutes and summaries not exceeding 250 words should be submitted via the appropriate national organization. The final dates of acceptance vary for the different countries from December 15 and January 31, but in any event the summaries must reach the Congress secretary-general by February 15.

Announcements

THE Committee of Privy Council for Agricultural Research and Nature Conservation has appointed Mr. Frank Rayns to fill a vacancy in the membership of the Agricultural Research Council, caused by the retirement of Prof. K. Mather. Mr. Rayns is director of the Norfolk Agricultural Station, Sprowston; he is chairman of the Experimental Husbandry Committee of the Agricultural Improvement Council for England and Wales and serves on the governing body of the National Institute of Agricultural Engineering. Prof. S. Zuckerman has been appointed a member of the Agricultural Research Council for a further term of office.

DR. NICOL GROSS, managing director of S.A.G. (Pty.), Ltd., Johannesburg, has been appointed to the University of London readership in production engineering tenable at the Imperial College of Science and Technology.

MR. IVOR BOWEN has retired from the post of principal director of Equipment Research and Development (Air) in the Ministry of Supply, and is taking up an appointment with the General Precision Equipment Corporation of the United States; his new post will be in London.

THE Third International Congress on Vitamin E will be held in Milan in September 1955. The following topics will be discussed: vitamin E and metabolic processes; influence of vitamin E on the hæmato-vascular system; vitamin E and the neuromuscular system; correlation between vitamin E and other vitamins and hormones. Further information can be obtained from Prof. Emilio Raverdino, via Pietro Verri 4, Milan.

THE Rockefeller Foundation has made a grant of 7,500 dollars to the University of Glasgow towards the expenses of three small working conferences of European scientists interested in genetical problems. The conferences will be held during the next five years, one probably in or near Glasgow and the others in localities to be decided.

THREE postdoctoral fellowships in statistics are being offered for 1955–56 by the University of Chicago. The purpose of these fellowships (of value 4,000 dollars each) is to acquaint established research workers in the biological, physical and social sciences with the role of modern statistical analysis in the planning of experiments and in the analysis of empirical data. Application forms can be obtained from the Committee on Statistics, University of Chicago, Chicago 37, and must be returned by February 15, 1955.

ERRATUM. In the communication "Seasonal Regulation in British Dragonflies" by P. S. Corbet in *Nature* of October 2, p. 655, the labelling of the axes of the graph should be interchanged; thus the ordinates indicate percentage of yearly population emerging per day, and the abscissæ successive days of emergence.

ORGANIZATION OF APPLIED RESEARCH IN EUROPE

THREE reports have been prepared by the Organization for European Economic Co-operation*, the first two of which embody the results of a study of the organization of applied research in various European countries, including the United Kingdom, made during October 6–November 15, 1951, and in the United States and Canada during April 21–June 11, 1952, by two Technical Assistance Missions, the comparative observations and general conclusions of the two Missions being collected in the first report. The third report, dealing at length with applied research in the United States and Canada, though undertaken at the request of the Organization for European Economic Co-operation, was prepared as a project of the National Research Council of the United States National Academy of Sciences, in co-operation with the Mutual Security Agency. To a certain extent it has since been superseded by studies carried out by the National Science Foundation, so far as applied research in the United States is concerned, with which roughly a hundred out of its hundred and twenty-five pages deal. Nevertheless, the broad sketch of American practice in the organization, administration and finance of applied research and of the methods used to facilitate the translation of research results into practice provide a most useful supplement to the earlier publications of the National Resources Planning Board, "Research—A National Resource", and to the Steelman report, "Science and Public Policy". It is supported by a brief but well-chosen bibliography, and the much slenderer survey of industrial research in Canada is equally well-balanced and appropriate to the purpose.

The volume on applied research in Europe contains much more material that is either fresh or—except perhaps in respect of that supplied for the United Kingdom or contained in papers presented to the international symposium sponsored by the Department of Scientific and Industrial Research in London in November 1951—not so conveniently accessible. The symposium was included in the programme of the first of the two missions, and a brief account of the symposium is included in the Mission's report, which emphasizes the value of comparing methods used in the various countries for the organization of research, particularly for the adaptation of new ideas to varying conditions, and the value of international collaboration in the effective distribution of technical information. More attention should be given to the application of research results and to the improvement of means of communication. Generally, in Europe the trend has been in favour of the co-operative research organization as opposed to the sponsored research institute; but both types are regarded as necessary, and there appears to be no reason why they should not work in harmony.

In Austria, the Federal Government, which is the chief supporter of basic research, provided 390,000 dollars for this purpose at the universities and technical colleges during 1952 as well as other contributions for basic and applied research and technical development to a total of 1,960,000 dollars, but only 58,600 dollars was provided for basic research from industry or other private sources. There are some three hundred and fifty experimental research stations in Austria, employing eight hundred graduate and nearly five hundred other staff, and two centres for disseminating technical information: the Documentation Centre for Technology and Economy and the Economic–Technological Service of the Austrian Productivity Centre.

Since the Second World War scientific research in Belgium has been organized mainly by the National Scientific Research Board, with an income during 1949–50 of 306,000 dollars (187,000 dollars from State grants) and the Institute for the Development of Scientific Research in Industry and Agriculture with an income, from the State, in 1951 of 1,895,000 dollars. About 65–75 per cent of the industrial and agricultural research programme supported by the latter body is carried out at the universities or higher educational institutions, but for industrial research a higher proportion is carried out in the laboratories of the research associations.

Technical research in Denmark is mostly built up around the institutes of higher learning, but there are several research institutes established by the Government, and the Academy of the Technical Sciences makes grants totalling 192,000 dollars to various technical institutions, while the Government contributes 1,442,000 dollars for technico-scientific research, as well as 50,000 dollars for the Research Council of the Technical Sciences and 36,000 dollars for scientific research. The General Scientific Foundation has recently been established to distribute a State grant of 288,000 dollars annually for research in basic science and in the agronomic and veterinary sciences.

Applied research in France is carried out chiefly in laboratories controlled by the State, the nationalized industries and private enterprise. The National Centre of Scientific Research, with an expenditure of 8,580,000 dollars during 1951, as well as 1,720,000 dollars on equipment, is concerned mainly with fundamental research but devotes some of its activities to practical applications. Some branches of industry have organized corporate research centres, but the structure of these bodies varies widely.

In Germany the Kaiser Wilhelm Society has been replaced by the Max Planck Society for the advancement of the sciences, which has already some sixteen institutes dealing with applied research, and had an income for 1953 of 4,240,000 dollars. The German Research Association, which functions chiefly through grants to individual research workers, had funds in 1953 amounting to 2,600,000 dollars, while the Fraunhofer Society for the Advancement of Applied Research, founded in 1949 and which is still being built up, has distributed about 714,000 dollars for applied research. Research associations have been formed for some industries, to which the League of Benefactors for German Science has contributed some 238,000 dollars for fundamental research, while Federal Government contributions to industrial research totalled 6·25 million dollars.

---

* Organization of Applied Research in Europe, the United States and Canada. Report of Technical Assistance Missions Nos. 81–82–83. Vol. 1: A Comparative Study. Pp. 80. 6*s.*; 1 dollar; 300 French francs. Vol. 2: Applied Research in Europe. Pp. 192. 12*s.*; 3 dollars; 600 French francs. Vol. 3: Applied Research in the United States and Canada. Pp. 120. 8*s.*; 1.25 dollars; 400 French francs. (Paris: Organization for European Economic Co-operation; London: H.M. Stationery Office, 1954.)

The main government organization for sponsoring research in Italy is the National Research Council, with an income for 1952–53 of 3 million dollars, while it is estimated that about 2·3 million dollars a year is spent on research in the universities, another 2·7 million dollars by government departments and nearly 250,000 dollars by the learned societies, professional associations and scientific foundations. Estimates are given of the expenditure on industrial research by individual firms—for example, 924,000 dollars each by the Montecatini Co. on chemical research and by the Fiat Co. on mechanical engineering research—but not for industrial research organizations as a whole.

In the Netherlands the Central National Organization for Applied Scientific Research has been responsible since 1932 for the direction of applied research in accordance with national needs and had a budget for 1951 of 3·4 million dollars, of which 2·37 million dollars came from the government and the remainder chiefly from industry. In Norway, where the universities themselves come under the Ministry of Education, most scientific and technical research, apart from that at the Christian Michelsen's Institute, Bergen, and that of the Society for Industrial and Technical Research at the Norwegian Technical College, Bergen, is carried out directly, under the government or with government assistance, which provided about 8 million dollars for research and development during 1952–53. The Royal Norwegian Council for Scientific and Industrial Research is responsible for the furtherance of fundamental research as well as for planning technical research in accordance with the needs of industry. Expenditure on scientific and technical research in 1952–53 is estimated at about 8·2 million dollars, of which 1·8 million was in universities and technical colleges, 2·1 million in public research institutes, 680,000 in institutes under the Council for Scientific and Industrial Research, and about 2·5 million dollars in industrial laboratories, with a research staff of about nine hundred, of which 290 are in the universities and technical colleges and 182 in public research institutes.

Information on research expenditure in Sweden is much less complete. The Royal Swedish Academy of Science received government grants amounting to 243,000 dollars during 1951–52 for research work at the Nobel Institute for Physics and Chemistry, the Stockholm Observatory and other institutes under its control. The Royal Swedish Academy of Engineering Sciences received a government grant of 25,000 dollars and also support from industry. Of the four State Research Councils, that for Technical Research had a budget for 1951–52 of 212,000 dollars, the Committee for Building Research 67,500 dollars and the Atomic Energy Committee 367,000 dollars. Applied research is carried out to some extent by various government laboratories which have a total budget of nearly 1·3 million dollars, while the combined budgets of the Forest Products Research Laboratory, the Textile Research Institute, the Metallographic Institute and the Food Preservation Research Institute are 776,000 dollars, of which 235,400 dollars are provided by the State. A survey of thirty-seven of the larger industrial research laboratories indicated that they employed a scientific and technical staff of 340 out of a total of 2,300, and the total expenditure on industrial research is estimated at about 10 million dollars a year. The interchange of information between research workers and industry is facilitated by the Researchers Contact Organization.

In Switzerland applied research is organized at the national level through the Society for the Promotion of Research at the Federal Technical College, the Commission for the Sponsoring of Scientific Research, the Swiss Research Council for Atomic Energy and the Swiss National Foundation for Scientific Research. No comprehensive data are available for Federal expenditure on research, but 936,000 francs were allocated for scientific research by the Federal Council in 1945, and the Swiss Federal Institute of Technology in 1951 received Federal credits amounting to 2 million dollars, the Swiss National Foundation for Scientific Research was to receive Federal grants increasing to 936,000 dollars in its third year, while some 3·25 million dollars were expended in 1951 on research and development by the Division of War Technology of the Federal Military Department. It is estimated that the firms of Ciba and Sandoz spend about 5·85 million dollars a year on research, and Brown Boveri about the same amount. The Aluminium Foundation was established by the Aluminium Industrie A.G. of Nordhausen to support promising investigations in applied chemistry, particularly electrochemistry and electrometallurgy, and a number of other Swiss firms and industrialists have established foundations for scientific research in medicine, biology, etc.

BRITISH INDUSTRY AND SCIENTIFIC MAN-POWER

THE first part of the address of Sir Harry Pilkington, president of the Federation of British Industries, to the annual meeting at Reading, on September 21, of members of the Southern Region of the Federation, stressed the importance of the export trade to the British economy and indicated that we are on the eve of another big effort by the Federation in this field, the Trade Fair at Baghdad. He said that we are the people in the whole world whose future, safety and survival most depends on the growth of international trade, and on the credit side that means the export of manufactured industrial products. We must constantly improve our productivity, attempt to increase our share of world trade, but still more expand the total of world trade and develop the purchasing power of growing markets overseas, including the raising of the standard of living of those people whose standards are far below our own.

Sir Harry said that the new industrial revolution under way completely overshadows that of the nineteenth century, and means a demand for more, and more highly qualified, scientists. The Federation's Education Committee is concerned here both with recruitment and training, including the shortage of science teachers. We shall not obtain the rise in productivity we require, he thinks, unless we have more people with a good scientific background—not merely more outstanding inventors, but more people competent to carry out the ordinary analytical work and team-work of development. Sir Harry then emphasized the high cost of invention to-day. This is now the result of team-work and leadership, and often involves enormous sums before inventions are developed to a commercial stage. He does not believe that Britain or any other country can afford to allow all its best scientists to work in isolated compartments on the same problem, without access at least to other people's mistakes. Broad views of the advantages of pooling resources of inventiveness, or of pooling results, are of the utmost importance to Britain and to mankind as a whole. He therefore urged industrial firms to re-assess the work of their research departments, and where research institutes or associations for the whole of the industry do not exist, to try to devise other means for pooling with their neighbours or their competitors results of their development work.

Sir Harry remarked that some of our man-power resources are still being used wastefully, and touching on the question of taxation said that to abolish de-rating would give a great shock to industrial confidence in Britain and undo all the good resulting from the encouragement given last April to investment in plant and machinery. He urged member-associations and individual firms to make their own cases showing what would be the effect, industry by industry, of a re-introduction of full rating on top of revised valuations.

Although Sir Harry complained of the high level of employment in the Civil Service, he welcomed the endorsement by the Government and the Civil Service as a whole of the findings of Sir John Wood's Committee in the Crichel Down case, and said that it is equally important that private citizens, and especially industry, should show like consideration to Civil servants.

BRITISH PHARMACEUTICAL CONFERENCE, 1954

THE ninety-first British Pharmaceutical Conference was opened at Oxford on September 13 and nearly five hundred members attended.

Dr. H. Davis, in his chairman's address, discussed the impact of National Health Service on pharmacy and outlined how the changing pattern of prescribing and dispensing demands from the pharmacist of to-day less manipulative skill but a more detailed scientific knowledge of drugs and processes than was formerly required. This changing demand is reflected in the research papers read at the Conference.

Two of the papers are of general interest. The first, on demineralized water, shows that with correct technique demineralization of tap water by mixed anion and cation exchange resins produces a water of purity at least equal to that of distilled water B.P. The second general paper was a discussion of entrainment of liquid in distillation. It was shown that when the flow of vapour in the still-head was in streamline flow, the amount of entrainment increased with diameter of still-head and was proportional to Reynolds number.

Research of specific interest to practising pharmacists included a study of the pH of the castor oil soap in the preparation of a solution of chloroxylenol in an attempt to obtain a constant product. The increased use of newer emulsifying agents is reflected in the report on polyethylene-glycol esters of cetostearyl alcohol, in which it was shown that when used alone the lower members of the series (two or four ethylene oxide units) are more effective in emulsifying arachis oil. Also in the emulsion field, an interesting point was that the addition of bentonite to certain cream bases will permit them to be autoclaved without creaming or separation of the oil.

Stability of preparations of drugs is always an important subject in pharmaceutical analysis. A quick iodometric method for estimating the hydrolysis of succinylcholine chloride, confirmed by chromatographic and biological assays, has shown that increased temperature (20° → 37° C.) greatly increases the instability of this drug. Since ferrous iron is more readily adsorbed than ferric iron, oxidation of ferrous gluconate solutions should be prevented; it has been found, by suitable formulation and storage in light, that the ferrous iron content of such a solution may increase slightly, but this is accompanied by some deposition from the solution. The most stable solution is a 10 per cent solution stored in small, completely filled containers, stabilized with 7·5 per cent dextrose monohydrate and stored protected from light.

It is interesting to find that the sugar coating of tablets of penicillin intended for oral use not only masks the bitter flavour but also protects the contained penicillin from external moisture, and so increases the stability that they can then be stored for two years at 25° C.

The instability of tincture of digitalis has been a puzzle, since the frog lymph sac method of assay showed loss of potency on storage whereas the cat intravenous method did not. Fresh light has been thrown on this subject by two workers who, using a frog intravenous method, have shown that this method also indicates a drop in activity on storage and so the disagreement between the two methods of assay is not due to differences in absorption. They suggest that on storage the primary glycosides in the tincture are hydrolysed to secondary glycosides but not down to the genins.

The correlation shown between three methods of measuring pyrogenic activity—temperature rise, fall in percentage of small lymphocytes and fall in average number of lobes per neutrophil—will give pharmacologists a double confirmation of the results of pyrogen tests.

A very neat method of studying the percutaneous absorption of substances from ointment bases has been devised. Injection of acetylcholine into a rat causes secretion of reddish-brown tears; this effect is increased by eserine, and the response can be used for an assay of the eserine. By incorporating the eserine in an ointment base and rubbing on the skin of the rat, the amount absorbed can be ascertained.

A number of papers on the analytical aspect of research were presented, including biological and chemical assays.

In a new type of apparatus it has been shown that the rate of disinfection of solids by formaldehyde vapour is dependent on the amount of vapour permeating the solid rather than the concentration of formaldehyde in the vapour.

The adsorption of phenol on activated charcoal, or on a precipitate caused when ferric chloride was added to the bacteriological medium used for detecting survivors from a phenol–*Bact. coli* mixture, showed no apparent effect on the survival-rate.

An infusion of raspberry leaves has a traditional use in giving easy and speedy parturition. Preliminary investigation into the active principles which may be responsible for this effect have led to the separation of three fractions, one a spasmolytic factor which may antagonize the stimulant effect of the other two factors, and might explain the negative results of clinical trials of raspberry leaf extracts. A standard method for the purification of such extracts should lead to more definite results from them.

The comparison of two types of assay for tincture of digitalis, the 18-hr. frog method and a chemical method using 3 : 5-dinitrobenzoic acid, has shown that the biological assay of this material is still the only sure way of ascertaining potency. Search for a means of characterizing sulphonamides by examination of their benzaldehyde and salicylaldehyde derivatives not only achieved the required results but also led to a rapid colorimetric method for the assay of sulphadimidine.

Two papers were read dealing with spectroscopy, one a general outline of infra-red techniques and the other on the determination of vitamin D.

The diverse chemical nature of synthetic analgesics led to a review of their stereochemistry, when it was found that the more analgesically active isomer of optical enantiomorphs has a spatial configuration related to that of D-(−)-alanine. The isolation, purification and identification of the constituents of the petrol extract of serpentary formed the basis of one paper, which illustrated the vast amount of work that still remains to be done before the true nature of many of the drugs in common use is elucidated.

Two new assay techniques were reported, one for benzathine penicillin and the other for quaternary ammonium compounds.

It was argued on statistical grounds that some of the present standards for surgical dressings given in the British Pharmaceutical Codex need review, in that in some cases the exacting specifications take no account of variations which are bound to occur in manufacture and can easily be measured and limits imposed.

With the increasing use of the tablet as a convenient method of dispensing solid drugs, it is not surprising to find the symposium session of the Conference devoted to tablets, when the preparation, standardization and dispensing of them were fully discussed.

GIOVANNI MARIA LANCISI (1654–1720)

ANATOMIST, pathologist, epidemiologist, sanitarian and clinician, and one of the most advanced thinkers in the history of the medical sciences, Giovanni Maria Lancisi was born in Rome three hundred years ago, on October 26, 1654. He studied medicine at the Collegio di Sapienza, where he obtained his doctor's degree at the age of eighteen. After serving for two years as assistant physician at the Santo Spirito Hospital, he was made a canon of the Church of San Salvatore College in 1678 and devoted himself to studying the medical classics. In 1684 he was appointed professor of anatomy at the Collegio di Sapienza and thirteen years later professor of the theory and practice of medicine. A great admirer of Boerhaave, he introduced his clinical methods into medical teaching. He was physician to three successive popes: Innocent XI, Innocent XII and Clement XI. It was at Clement's request that in 1707 he wrote his monumental treatise "De subitaneis mortibus", in which he carefully records the pathological lesions of the brain and heart observed at autopsy, gives the first description of syphilis of the heart and of growths on the valves, and lists hypertrophy and dilatation of the heart as a cause of sudden death.

Lancisi's book, "De motu cordis et aneurysmatibus" (1728), is another landmark in the history of heart disease, for it stresses the significance of heredity, syphilis and violent emotions as causes of aneurysm. In his work "De noxiis paludum effluviis eorumque remediis" (1717) he showed remarkable insight into the theory of contagion and the possible transmission of malaria by mosquitoes. He described the natural history of the mosquito, suggested repeated examination under the microscope of the blood of malarial patients, recommended with poetic fervour cinchona bark as a remedy, and pointed out the connexion between stagnant water and mosquitoes as vectors of the disease. For the prevention of malaria he advocated the draining of marshy lands and their drying up by conservation of forests. He also wrote on equine and bovine pest.

Appreciating the relation of anatomy to sculpture and painting, Lancisi, in 1691, persuaded Bernardino Genga, professor of anatomy and surgery in Rome, to publish for the use of students his studies of anatomy made from the works of the ancients, and he himself published and edited in 1714 the "Tabulae anatomicae" of Eustachius, which had lain unused in the Vatican Library for more than 150 years. In the following year he wrote "A Correct Curriculum of Medical Studies", in which he emphasized the need of a preliminary education and the value of regular visits to other medical clinics. His library of twenty thousand rare books and manuscripts (Biblioteca Lancisiana), which he presented to the Santo Spirito Hospital in 1711 for the use of young physicians and surgeons, and for the maintenance of which he left a generous legacy, represents one of the first public medical libraries.

Paradoxically, Lancisi, whose signature is writ large on so many pages of anatomy, is eponymously commemorated solely by Lancisi's nerves—striae longitudinales on the upper surface of the corpus callosum.

A small man with lively expression and exuberant spirits, affable and diplomatic in company, Lancisi was a tremendous worker of amazing versatility, who carried on an extensive correspondence with the most famous scientists of his day. He died in Rome on January 21, 1720, at the age of sixty-six. In the tercentennial year of his birth he is gratefully remembered chiefly for having laid the foundation for a true understanding of the pathology of the heart.

SOCIETY FOR VISITING SCIENTISTS

ANNUAL REPORT FOR 1953–54

THE annual report for 1953–54 of the Society for Visiting Scientists, the seventh report of the Society, opens with an account of the financial state of the Society, which though it is disappointing is by no means hopeless, and under the energetic direction of the honorary treasurer, Prof. A. Haddow, fresh appeals will be made to the scientific industry to support the Society (preferably by deed of covenant) and to individual scientific workers to become members.

The Society's library and lounge are available to scientific societies on payment of a small fee, and it is hoped that in future more use will be made of these facilities. The premises were redecorated during the year, and they have a very pleasing appearance. As a result of the financial stringency, a certain amount of economy in the activities of the Society has had to be enforced during the year, but receptions were arranged for the delegates to two conferences—one on nucleic acids, organized by the Faraday Society, and the other by the General Assembly of the International Union of Pure and Applied Physics—and members of the Bureau of the International Council of Scientific Unions were also received on the occasion of their meeting in London in the spring. Of the three evening meetings held during the year, one consisted of scientific films on the petroleum industry, and another was a lively discussion on "The Science of Clothing". The third gathering was prompted by the occasion of the meeting in London of the Executive Committee of the International Geographical Union, and a discussion was arranged on "World Population".

The Overseas Science Students Association, which was started two years ago with the help of the Student Department, Student Welfare Department and the Science and Engineering Department of the British Council, has continued to hold its regular weekly meetings.

Although there were few 'major' occasions, the principal function of the Society—to act as a day-to-day centre in London for all scientific workers, both from overseas and those resident in Britain—was maintained, for which no little credit is due to the secretary, Miss E. Simpson. The officers of the Society are: *President*, Prof. A. V. Hill; *Honorary Secretaries*, Prof. F. J. M. Stratton and Mr. A. Lang Brown; *Treasurer*, Prof. A. Haddow; *Chairman of the Programme Committee*, Mr. G. A. McMillan; and *New Member of Council*, Sir Lawrence Bragg.

BUILDING RESEARCH STATION

REPORT FOR 1953

THE report for 1953 of the Building Research Board, to which is attached the report of the director of building research, Dr. F. M. Lea, this latter taking up the major part of the publication (pp. 66. London: H.M.S.O., 1954; 3*s*. 6*d*. net), is chiefly impressive for the very great amount and variety of research that has been undertaken at the Building Research Station, Garston, near Watford. Perhaps this is not altogether surprising, since the staff at the Station numbers more than four hundred, half of whom are officers in the scientific and experimental grades.

The director's report is divided into seven sections entitled: materials; design and performance of structures; soil mechanics; building operations; efficiency of buildings; the Scottish Laboratory; and Colonial housing and building research. In materials alone, the problems are becoming exceedingly varied and complicated as more and more different sorts of materials are invented and developed. But, of course, building research does not end with materials. There are the various types of building, from small dwelling-houses to large industrial premises, and it is with regard to the latter that many interesting developments are taking place, particularly in such media as prestressed concrete. Then, too, there is the question of building methods, productivity and costs, and the development of mechanical aids in building, of which the rail-operated tower crane is a case in point. The scope of building research extends to such problems as flooding, sea-defence banks and dams.

The Scottish Laboratory is more and more providing a means of extending investigations at the main Station, though there are particular Scottish problems, such as the utilization of local stone. In Colonial research, the work revolves around the activities of the Colonial liaison officer, who has been making extensive tours, mainly in Africa, looking into problems and arranging for the right organization to work on them. As yet, the only body in Africa engaged exclusively on building research is the South African National Building Research Institute, but plans are being laid for building research to be undertaken in British West Africa, the French African Territories and the Belgian Congo, as well as a certain amount of work on materials in Kenya and Southern Rhodesia.

Finally, mention must be made of the Building Research Board's concern at the reduction in finance during 1953, which severely curtailed long-term and short-term research, leaving the resources more concentrated on advisory work and the practical application of research. The Board feels strongly that its function is to promote not only work of immediate use but also that which will yield returns in the more distant future, and it is to be hoped that the recent lifting of financial restrictions on the Department of Scientific and Industrial Research will be reflected in the allocations to building research.

PLANT CULTIVATION IN SALINE AND BRACKISH WATER

THE raising of plants under saline conditions is a common problem in arid areas, where there is little leaching of the soil by rainfall and where the water available for irrigation has often a high salt content. In the fourth volume produced under the Unesco Arid Zone Programme*, the utilization of saline water is dealt with in three reviews, which not only provide a useful summary of existing information, but also, by emphasizing the gaps in our knowledge, serve as pointers to further research.

The first review, by Georges Grillot, of the Centre de Recherches Agronomiques, Rabat, Morocco, is based on research carried out in Africa, Europe and the Middle East. It deals with the biological problems presented by the growth of plants in saline or alkaline environments, and includes a particularly thorough section on the use of saline water for irrigation. Some of the important data are concisely set out in nine appendixes, among which is a table of natural halophytes "indicative of the corresponding cultivability of domestic species". One of the principal conclusions of the review is that both research and actual practice show that irrigation by saline water is not necessarily harmful. Certain types of soil, however, may be impoverished by even slightly saline water; but since vegetation is tolerant of higher degrees of salinity, the problem is one for the soil chemist rather than directly for the biologist.

---

* Arid Zone Programme. Reviews of Research on Problems of Utilization of Saline Water Pp. 96. (Paris: Unesco; London: H.M.S O., 1954.) 1 75 dollars, 500 francs, 10*s*. 6*d*

The second review is by Dr. H. E. Hayward, director of the United States Salinity Laboratory, Riverside, California, and covers research in the Americas, Australia and India. The practical problems encountered in the various geographical regions receive a comprehensive treatment; but more space is allotted to an interesting general account of basic physiological problems. Subjects discussed include the physiological basis for salt tolerance, the physiological basis for alkali tolerance, the effect of saline and alkali soils on plant growth, toxic effects of specific ions and salt tolerance in relation to germination. It is concluded that one of the main effects of moderate levels of soil salinity is to limit water supply to the plant by increasing the osmotic pressure of the soil solution. This effect is intensified by an increase in soil moisture tension, and the combined effect, total soil moisture stress, conditions the growth of plants. Over and above the osmotic effect, each component of the saline solution may have some specific toxic effect which may vary among various genera, species and varieties of agricultural crops. Because of this specificity in salt tolerance, it is important to make a proper selection of crops for use on lands that are marginal because of salinity.

The third review, by Dr. Everett D. Howe, of the Faculty of Engineering, University of California, is restricted to a consideration of methods of purification of salt and brackish waters. The development of an economically feasible method of carrying out such a purification on a large scale is clearly of the greatest importance, but has evidently not yet been achieved.

The reviews are clearly written and although their main value will be to those engaged in the agricultural development of saline regions, they have much of interest for many readers, particularly for the plant physiologist or ecologist.

A. ALLSOPP

HOUSEFLIES RESISTANT TO A GROUP OF CHLORINATED HYDROCARBON INSECTICIDES

By DR. J. R. BUSVINE

London School of Hygiene and Tropical Medicine

IN general, DDT has been the subject of far more research than other chlorinated hydrocarbon insecticides and, in particular, this is true of investigations of insecticide-resistance in houseflies. It seems that resistance to the insecticides γ-BHC, chlordane, dieldrin, aldrin and toxaphene is quite distinct from DDT-tolerance. These compounds must have some factor in common, since selection by exposure to one of them raises the resistance of a fly strain to the others. Questions which now arise are: Is there a single defence mechanism which protects resistant flies from all these compounds; and what is the common factor which defines this group of insecticides?

As regards DDT tolerance, there is evidence of at least two defence mechanisms, which may be more or less developed in different strains of fly, and thereby modify the type of resistance displayed. This has been exemplified by two strains of DDT-resistant flies, which showed marked differences in relative susceptibility to a range of DDT analogues[1].

It seemed possible that a similar type of investigation might reveal whether resistance to the γ-BHC–chlordane group of chlorinated compounds was equally heterogeneous. The method used was to determine the exact degrees of resistance, to a series of related compounds, shown by four strains of flies from very different sources. The strains of houseflies used were: (1) Sardinia strain. Previous history in the field: DDT house-spraying throughout the island during 1947–50; chlordane added to the spray from 1948; laboratory colony started in November 1950. (2) England strain. Previous history in the field: from a refuse tip at Egham, treated with DDT during 1947–49; during 1951–53 treated with BHC; laboratory colony started in September 1953. (3) Omdurman (Sudan) strain. Previous history in the field: all pit latrines and other breeding sites near the town dusted with BHC during 1949–52; in 1950, many houses sprayed with DDT; laboratory colony started in March 1953, through the kindness of Dr. D. J. Lewis. (4) Uruguay strain. Previous history in the field: widespread use of BHC and DDT; laboratory colony started in 1951; a subcolony kindly sent to me by Mr. Newman, of Imperial Chemical Industries, Ltd., in January 1954. (5) Normal strain. Reared in the laboratory for many years and believed to be normally susceptible to insecticides.

Samples of males of the above strains were collected and, on the fresh specimens, the ratios head width/frons width were calculated, with the following results: Sardinia, 6·81 ± 0·44; England, 5·98 ± 0·38; Omdurman, 10·94 ± 1·45; Uruguay, 5·17 ± 0·46; normal, 5·14 ± 0·46. The Omdurman strain is clearly of the *M. domestica vicina* type, while the England, Uruguay and normal colonies are of the *M. domestica domestica* form. The Sardinia ratio is a little high, but approximates to the latter. These figures agree with those of Sacca[2], though I find the difference between colonies of *domestica* and *vicina* to be more constant than he suggests. Thus, after a year in my laboratory, the Omdurman ratio was found to be 11·14 ± 1·40, so that it had not changed appreciably.

Measurements of relative resistance. Purified samples of the following seven compounds were kindly supplied by the Shell Co., Ltd.: α- and β-chlordane (1, 2, 4, 5, 6, 7, 8, 8-octochloro-4, 7-methano-3a, 4, 7, 7a-tetrahydroidane); it is believed that α- and β-chlordane differ in regard to the position of chlorine atoms on carbons 1 and 2, α being a *trans*-

Table 1. MEDIAN LETHAL CONCENTRATIONS OF VARIOUS INSECTICIDES TO DIFFERENT STRAINS OF HOUSEFLY

Fly strain	Median lethal concentration (per cent)							
	Chlordane alpha	Chlordane beta	Isodrin	Endrin	γ-BHC	Aldrin	Dieldrin	DDT
Uruguay	30	9	0·5	0·3	0·8	7	3	0·35
Omdurman	18	4	0·35	0·2	0·5	2	1·5	0·6
Sardinia	3·5	0·3	0·1	0·05	0·09	0·4	0·25	1·8
England	2·0	0·4	0·09	0·06	0·1	0·22	0·14	1·0
Laboratory	0·04	0·018	0·015	0·009	0·008	0·007	0·006	0·08

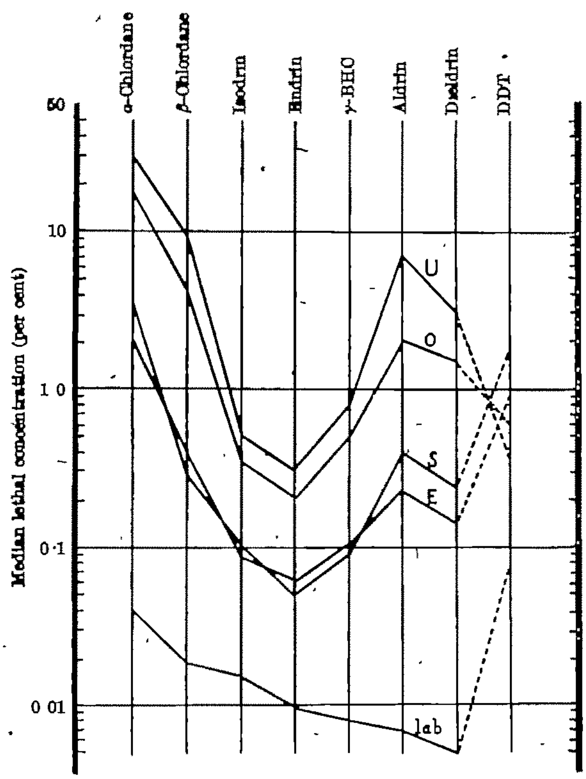

Fig. 1. Relative resistance to chlorinated hydrocarbon insecticides in houseflies. The logarithmic scale on the left indicates the median lethal concentration of various insecticides, which are shown as vertical lines. These, with the exception of DDT, are arranged in order of toxicity to the normal laboratory strain of flies (lab.). The irregular lines display the similar resistance 'pattern' of the following strains: U, Uruguay; O, Omdurman; S, Sardinia; and E, England

and β a *cis*-isomer; both are thought to be *endo* forms in respect of the isomerism about the 3*a*–7*a* carbon bond. Dieldrin and endrin (1, 2, 3, 4, 10, 10-hexachloro-6, 7-epoxy-1, 4, 4*a*, 5, 6, 7, 8, 8*a*-octahydro-1 : 4, 5 : 8-dimethanonaphthalene); dieldrin is an *endo–exo*- isomer, whereas endrin is the *endo–endo*- form. Aldrin and isodrin (1, 2, 3, 4, 10, 10-hexachloro-1 : 4, 5 : 8-dimethano-1, 4, 4*a*, 5, 8, 8*a*-hexahydronaphthalene); aldrin is an *endo–exo*-isomer, whereas isodrin is the *endo–endo*- form. γ-BHC (γ-1, 2, 3, 4, 5, 6-hexachloro-cyclohexane).

These insecticides were dissolved in refined, high-boiling mineral oil (Shell risella oil), and their toxicities to the various fly strains determined by droplet applications, as in previous investigations[1]. The median lethal concentrations were estimated, the results being set out in Table 1 and illustrated by Fig. 1.

These results have certain interesting characteristics. It will be seen that the 'pattern' of resistance of the four fly strains is remarkably similar, despite their different histories and origin in such diverse geographical areas. All of them have developed highest resistance to α- and β-chlordane, dieldrin and aldrin. Resistance is intermediate to γ-BHC, and it is least developed against endrin and isodrin. Though three of the strains acquired resistance by the selective action of BHC used in the field, yet in all cases resistance to chlordane, dieldrin and aldrin is higher.

Possibility of a common defence mechanism. The results strongly suggest that the four strains depend on the same defence mechanism for dealing with insecticides of this type, though it may be more highly developed in some strains than others. From Fig. 1 it will be observed that the compounds aldrin and dieldrin, and the two isomers of chlordane, retain the same order of toxicity to the resistant as to the normal flies. In contrast, endrin, isodrin and γ-BHC, which are intermediate in toxicity to normal flies, are decidedly more toxic to resistant ones than the group mentioned above. This change is puzzling; but, indeed, the reasons for the original order of toxicity to normal flies is equally obscure. In a later paragraph it will be suggested that all these compounds have similar insecticidal action by reason of similar toxophores. If this is so, their individual levels of toxicity might depend on characters of the whole molecules, affecting such things as phase distribution or efficiency of absorption or diffusion. It is conceivable that these characters might have different effects at the high concentrations necessary for the resistant flies.

Another possible explanation could be offered if the resistance mechanism depended on detoxification; for this might well be more efficient with some compounds than others. Then, for example, one would expect dieldrin introduced into resistant flies to disappear faster than endrin.

The following tests were conducted. Batches of resistant females were injected with 0·1 per cent oil solutions of dieldrin or endrin. After various periods, the flies were ground up and extracted with ether and the insecticide remaining in the residue estimated

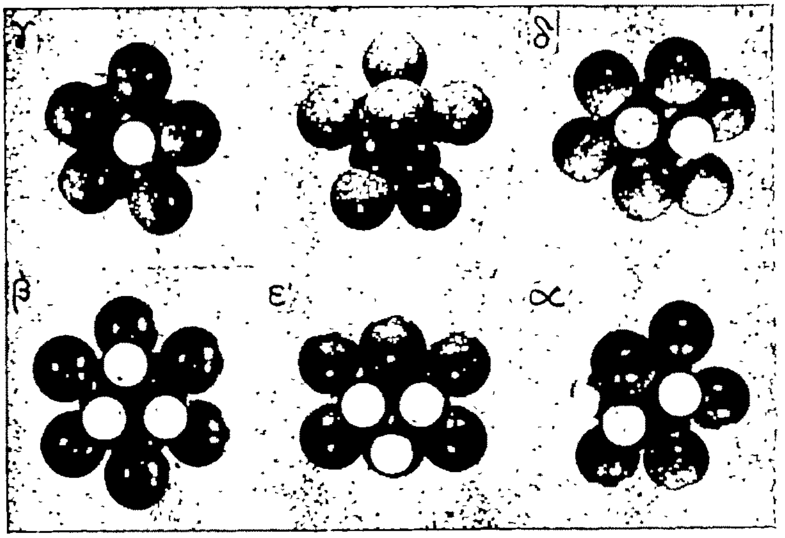

Fig. 2. Molecular models of α-, β-, γ-, δ- and ε-BHC and (top centre) end-view of a molecule of either chlordane, dieldrin, aldrin, isodrin or endrin, all of which have a somewhat similar pentagon. Key to the colours: black, carbon; white, hydrogen; grey, chlorine. It will be seen that for BHC the pentagonal arrangement of chlorine atoms occurs only in the γ form. (The bonding angles in the 6-membered carbon rings in these compounds are somewhat strained and the carbon balls have been slightly modified by Dr. S. L. Thomas to obtain a fit. In consequence, this model cannot be used for an accurate estimate of molecular dimensions.) The models were made by Messrs. Catalin, Ltd., according to specifications of Settatree, Thomas and Yardley (ref. 3)

Table 2 EXTRACTION OF DIELDRIN AND ENDRIN (μgm./fly): (a) FOR LIVING AND DEAD FLIES, RESPECTIVELY, AFTER 30 HR.; (b) LIVING AND DEAD FLIES TOGETHER, AFTER 0, 40 AND 70 HR.

	Living	Dead
(a) Dieldrin	0·21	0·24
Endrin	0·26	0·28

	0 hr.	40 hr.	70 hr.
(b) Dieldrin	0·26	0·24	0·19
Endrin	0·23	0·17	0·14

by bioassay, by wire-loop applications to susceptible male flies (Table 2).

These limited data suggest that the different degrees of resistance developed to these two compounds do not depend on relative ease of elimination.

Common factor of the γ-BHC–chlordane group. The second question mentioned earlier was the problem of the common factor of the γ-BHC–chlordane group of insecticides. The compounds chlordane, aldrin, dieldrin, endrin and isodrin have obvious similarity in part of their molecules; but γ-BHC appears quite different when represented graphically. When molecular models are prepared, however, it may be observed that five of the chlorine atoms of the chlordane group are arranged approximately symmetrically, with a sixth protruding from the centre. Models of the various isomers of hexachlorocyclohexane reveal a rather similar pentagon of chlorine atoms in the γ-form only (Fig. 2). It seems likely that this is the toxophore responsible for the high insecticidal activity of γ-BHC and the chlordane type insecticides. It may also explain the correlated resistance developed by flies to members of the group.

Additional evidence for this hypothesis was obtained by tests with a sample of octochloropropane, a highly chlorinated hydrocarbon not possessing a pentagonal arrangement of chlorine atoms. The median lethal concentration of this compound was found to be approximately 20 per cent for both the Omdurman and the laboratory strains. Thus, this substance is not highly insecticidal, nor does resistance to the γ-BHC–chlordane series alter the level of susceptibility to it.

Apart from chemical considerations, observations of the progress of intoxication in flies reveal similar features in γ-BHC and the chlordane group, which are quite different from signs of DDT poisoning. DDT causes continual, unco-ordinated movements; but until a late stage of intoxication, the wings can function normally. Flies poisoned by γ-BHC or by a member of the chlordane group frequently show 'fanning' movements of the wings, insufficient to cause flight. At a late stage of intoxication, the legs are all tightly contracted under the body and the wings are usually deflected downwards (cf. Weismann[4]).

It is interesting to learn that, in mammals, there is an analogous difference in signs of poisoning by DDT as compared with those due to the γ-BHC–chlordane group of insecticides. Dr. J. M. Barnes, of the Medical Research Council Toxicology Research Unit, kindly allows me to quote his observations, as follows: "When these insecticides are dissolved in 'Tween 80' (polyoxyethylene sorbitan oleate) and injected intravenously into rats, there are two types of effect. DDT and methoxychlor, like phenol, produce widespread muscular twitchings. The intensity of the tremors depends on the dose. In the case of DDT, convulsions are relatively minor in severity and come as a cumulation of the violent tremors. Death may not take place for 1–2 hours. With *gamma* BHC, aldrin, endrin, dieldrin and chlordane, fine muscular twitchings are not seen. The outstanding feature is convulsions, of sudden onset and extreme violence, often starting within a few minutes of giving a dose that is just lethal. Death may occur during convulsions, or after a period of unconsciousness following the convulsions. Death, if it occurs, usually takes place within 10–15 minutes".

PHOTOLYSIS OF CHLORINE DIOXIDE AND ABSOLUTE RATES OF CHLORINE MONOXIDE REACTIONS

By F. J. LIFSCOMB, PROF. R. G. W. NORRISH, F.R.S., and DR. G. PORTER

Department of Physical Chemistry, University of Cambridge

THE absorption spectrum of chlorine monoxide was first detected in the photochemical reaction between chlorine and oxygen[1,2] and all direct studies of its reactions have so far been carried out on this system. The mechanisms of these reactions have been thoroughly elucidated, but[3] it has been necessary to express the absolute rates and concentrations in terms of an unknown constant which is numerically equal to the extinction coefficient of chlorine monoxide at a given wave-length. The evaluation of this constant would lead to absolute extinction coefficients of chlorine monoxide at all wave-lengths, absolute concentrations under any required conditions and absolute rate constants of the reactions of chlorine monoxide.

The extinction coefficient appears in these quantities because the observed parameter is an optical density, D_λ, of the reaction mixture at a given wave-length λ. We then have

$$D_\lambda = \varepsilon_\lambda c l,$$

where ε_λ is the extinction coefficient of chlorine monoxide at this wave-length, c is its concentration and l is the length of the absorption path. It is therefore possible only to measure the product $\varepsilon_\lambda c$ and not the separate quantities. Since the relative extinctions at two wave-lengths are easily obtained, all can be referred to a standard extinction, ε_s, at a wave-length of 2577 A., which is in the continuous region of the spectrum and is therefore insensitive to the exact wave-length and independent of the resolving power of the spectrograph.

The ClO radical is removed by the bimolecular process:

$$2ClO = Cl_2 + O_2; \qquad (1)$$

and the rate constant of this reaction is given by

$$k_1 = 7{\cdot}2 \times 10^4 \times \varepsilon_s \exp \frac{(0 \pm 650)}{RT} \text{ litre mole}^{-1} \text{ sec.}^{-1}.$$

To evaluate ε_3, the concentration of chlorine monoxide must be known and, in principle, this can be found by difference if the concentrations of the other species present are known. Thus, in the reaction between chlorine and oxygen, the only species which contain chlorine and which are present in significant concentrations are chlorine monoxide and chlorine, and the decrease in concentration of chlorine should lead directly to the concentration of chlorine monoxide. Unfortunately, owing to the low extinction of chlorine, this decrease of concentration was below the limit of detectability and it was therefore only possible to give a lower limit for ε_3 which was 310. Reasons were given for supposing that ε_3 was less than 3,000, but no further limits could be fixed by these experiments.

The extinction coefficient of chlorine dioxide is much greater than that of chlorine and is of the same order of magnitude as the above predicted values for chlorine monoxide. It follows that, if chlorine monoxide were detected during the photolysis of chlorine dioxide, the decrease in concentration of chlorine dioxide should be readily measurable. We have therefore investigated this reaction by the same experimental methods as were used to study the chlorine–oxygen reaction. The photolysis flash was operated with an energy of 250 *J* and had an effective duration of 100 μsec. Pressures of chlorine dioxide were ½ mm. mercury or less, and the experiments were conducted in the presence of up to half an atmosphere of inert gas (argon, nitrogen or carbon dioxide) in order to reduce the rise in temperature to a few degrees. Plate densities were measured by reference to calibrations made with a neutral step wedge.

It was found that a single flash decomposed about 90 per cent of the chlorine dioxide and that this spectrum was replaced by that of chlorine monoxide, which then decayed slowly in the same manner as had been observed in previous work. Spectra of other chlorine oxides were absent at all times, and microphotometric measurements at 2780 A. established that chlorine trioxide (ClO_3), which has an extinction coefficient of 1,210 at this wave-length[4], could not have been formed in an amount greater than 1 per cent of the total chlorine dioxide decomposed. This is different from the photolysis of chlorine dioxide at normal intensities, where chlorine trioxide is a major product[5], but the difference can be understood in terms of the following competing reactions:

$$O + ClO_2 = ClO_3 \qquad (2)$$

$$O + ClO = ClO_2 \qquad (3)$$

$$O + O + M = O_2 + M \qquad (4)$$

Since the ratio of the concentration of atomic oxygen plus chlorine monoxide to the dioxide is many thousand times greater in the flash experiments, the probability of reaction 2 relative to 3 and 4 will be correspondingly reduced.

The primary photolysis undoubtedly occurs by the process:

$$ClO_2 + h\nu = ClO + O\,; \qquad (5)$$

and therefore, if measurements are made before the chlorine monoxide has reacted to form chlorine, the concentration of chlorine monoxide will be given simply by the difference between the corresponding concentration of chlorine dioxide and the concentration originally present. Allowance was made for the chlorine monoxide which had reacted before measurement by carrying out a number of determinations at pressures of chlorine dioxide of 0·1, 0·2 and 0·5 mm. mercury, and extrapolating to zero concentration. The correction was very small, the observed value at the lowest chlorine dioxide pressure being only 4 per cent less than the extrapolated value, while the mean deviation from the mean at a given pressure was 7 per cent. The final value of the extinction coefficient at 2577 A. obtained in this way was 1,190 ± 100 litre mole^{-1} cm.$^{-1}$. Substituting this numerical value into the expression of Porter and Wright, we obtain:

$$k_1\ (20^\circ\ \text{C.}) = 8{\cdot}6 \times 10^7 \text{ litre mole}^{-1}\text{ sec.}^{-1}.$$

We have also measured the rate constant of removal of chlorine monoxide independently, using the same methods but preparing it by photolysis of chlorine dioxide. The mean value of the bimolecular constant obtained at 20° C. was $5{\cdot}7 \times 10^7$ litre mole^{-1} sec.$^{-1}$. The difference between these two values is probably within the combined errors of the two completely independent determinations, which used different density standards for plate calibration. It follows that chlorine dioxide, like chlorine and oxygen, has no effect on the rate of disappearance of the ClO radical.

It has been pointed out that reaction 1 has a low frequency factor and the reasons for this have already been discussed[3]. It is one of the simplest bimolecular radical reactions for which quantitative rate data and spectroscopic constants are now available for more detailed theoretical treatment.

RESTRICTION OF INFLAMMATORY RESPONSE BY POLYSACCHARIDES

By M. SHILO, B. WOLMAN and SHLOMO HESTRIN

Laboratory of Microbiological Chemistry, Department of Biochemistry, Hebrew University–Hadassah Medical School, Jerusalem

THE suggestion that colloids from the blood plasma may coat the capillary endothelium and that the porosity of the latter may thereby be reduced was advanced more than a decade ago[1]. However, the possibility of utilizing this mechanism as a means of restricting inflammatory response has perhaps not been appreciated clearly. Water-soluble polysaccharides frequently occur on micro-organisms in the form of capsular envelopes. It is relevant to the mechanism of infection and of interest to learn whether such polymers also can act on blood vessels as wall-coating agents. In the experiments described here, we have attempted in particular to ascertain whether neutral and high-molecular bacterial polysaccharides, lævan and dextran, systemically administered, retard escape of blood colloids and cells across the capillary wall at sites of tissue injury.

The influence of the intravenous administration of high-molecular polysaccharide on the capacity for acute inflammatory responses to local irritants is illustrated by the results in Table 1. The saccharide used was native lævan of *Aerobacter levanicum* (3 per cent in saline), given intravascularly before the irritant in doses of 100 mgm./kgm. in rabbits and guinea pigs, and of 500 mgm./kgm. in mice. This preparation, though apparently non-toxic towards the mice and guinea pigs, evoked an untoward reaction (immediate diarrhœa and occasionally death) in a few rabbits. The irritants were: (1) peptone, 0·1 ml. of 10 per cent 'Difco' proteose peptone in saline; (2) turpentine, 0·005 ml.; (3) staphylococcus, 0·1 ml. of a suspension of a *Staphylococcus* sp. grown on an agar slant for 24 hr., washed and finally suspended in 5 ml. of saline. These findings show that inflammation throughout an area of injury can be markedly restricted or prevented both by a lævan and a dextran. The same effect was uniformly present in systems involving different irritants, tissues and hosts.

Table 1. INFLUENCE OF HIGH-POLYMER LÆVAN ON ACUTE INFLAMMATORY RESPONSES

Irritant	Route of irritant	Animal	Reactions no lævan	Reactions lævan
Peptone	Intradermal	Rabbit	+ (*a*)	—
Turpentine	Intradermal	Rabbit	+ (*a*, *b*)	—
Staphylococcus	Intradermal	Rabbit	+ (*a*, *b*, *c*, *d*)	—*
Staphylococcus	Intradermal	Guinea pig	+ (*b*, *c*)	—*
Staphylococcus	Intra-peritoneal	Mouse	+ (*e*, *f*)	—

* When the high-polymer dextran of *Leuconostoc mesenteroides* was used instead of lævan, the same gross result was obtained.

+ indicates the presence of the inflammatory responses listed in parentheses; — their absence or marked diminution.

a – local blueing reaction within 1 hr. when 5 ml. of 1 per cent trypan blue in saline was administered intravenously immediately before irritant;

b – local œdema at 4 hr.;

c – local erythema at 4 hr.;

d – diapedesis at 1 hr. as observed in histological preparations;

e – markedly increased number of leucocytes in peritoneal exudate at 4 hr.;

f – marked elevation of the amount of an agglutinin (*Salmonella typhi O* 901 rabbit antiserum) in the peritoneal exudate 4 hr. after the intravenous administration of the agglutinin.

A *Staphylococcus* sp. injected intradermally into normal guinea pigs and rabbits evoked skin lesions which were soon localized and became purulent within a day. In hosts with diminished inflammatory responsiveness, such skin lesions are known to be non-purulent and to show a tendency to spread[1]. When rabbits or guinea pigs received lævan or dextran systemically, the intradermal inoculation of the staphylococcus regularly evoked a spreading and necrotic rather than a purulent lesion (see Fig. 1). These findings have strongly supported the concept that the promoting effect of lævan and dextran on infection is mediated by the ability of the polysaccharides to arrest inflammatory responses[3].

Dr. E. Margoliash in this laboratory has also found that subcutaneous resorption of a foreign tissue (fragments of a transplantable mouse mammary carcinoma) in the rat can be greatly retarded by daily intraperitoneal injection of lævan: the resorption in the normal rats was advanced in four to five days; resorption was less marked after two weeks in the 'lævanized' animals. Thus it appears that the lævan can inhibit a presumably chronic process of inflammation and not only the acute inflammatory responses.

The question arises whether the polysaccharides prevent or simply mask the capillary injury. We observed that 1–3 hr. old skin lesions produced in rabbits by intradermal injection of turpentine show an almost instantaneous blueing reaction with intravenously injected trypan blue. When rabbits with the preformed skin lesions received lævan 30 min. before the injection of the dye, the blueing reaction at the injured sites was prevented or greatly diminished and delayed. This suggests that lævan effects the rapid masking of the capillary injury.

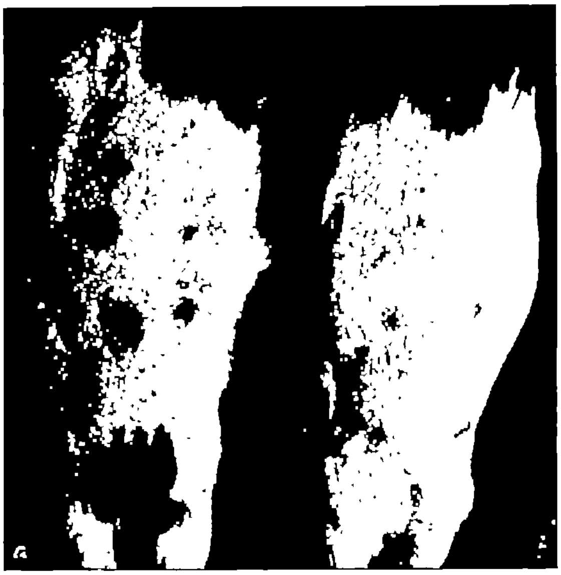

Fig. 1. Influence of high-polymer lævan on a cutaneous staphylococcus infection. guinea pigs infected intradermally at several dorsal sites. The inoculum was 0·1 ml. of suspension of washed cells of a *Staphylococcus* sp., the doses corresponding respectively in the lesions of the left and right rows to 1/50 and 1/500 of an agar slant. Lævan (150 mgm.) was administered intravenously. Photographs show lesions after six days. Lesions are purulent and localized in the non-lævanized control (*b*), whereas they are non-purulent, characteristically necrotic, and cover a relatively large skin area in the lævanized animal (*a*)

Both the ability to restrict inflammatory response and the attendant ability to promote infection are manifested by some shocking agents[2] and by cortisone[4] as well as by the polysaccharides. However, the mechanisms whereby these classes of substances affect the inflammatory response could, of course, be quite distinct. The activity of the polysaccharides was diminished greatly or abolished when molecular weight was reduced from greater than 10^6 to 10^4–10^5, which is the range acceptable in a plasma expander. Hence the activity is not determined solely by the structure of the polymer repeating-unit. The activity, however, could well be simply a function of capacity, dependent on molecular size, for adsorptive combination and resulting formation of an extraneous polysaccharide coat on the surface of the endothelium (cf. ref. 5).

A detailed report and discussion of clinical implications will be presented later. We thank Dr. M. Wolman for criticism and the analysis of histological preparations. Support of the investigation by a grant from the Scientific Department, Defence Ministry of the Government of Israel, is gratefully acknowledged.

Contraction and Relaxation of Collagen Fibres

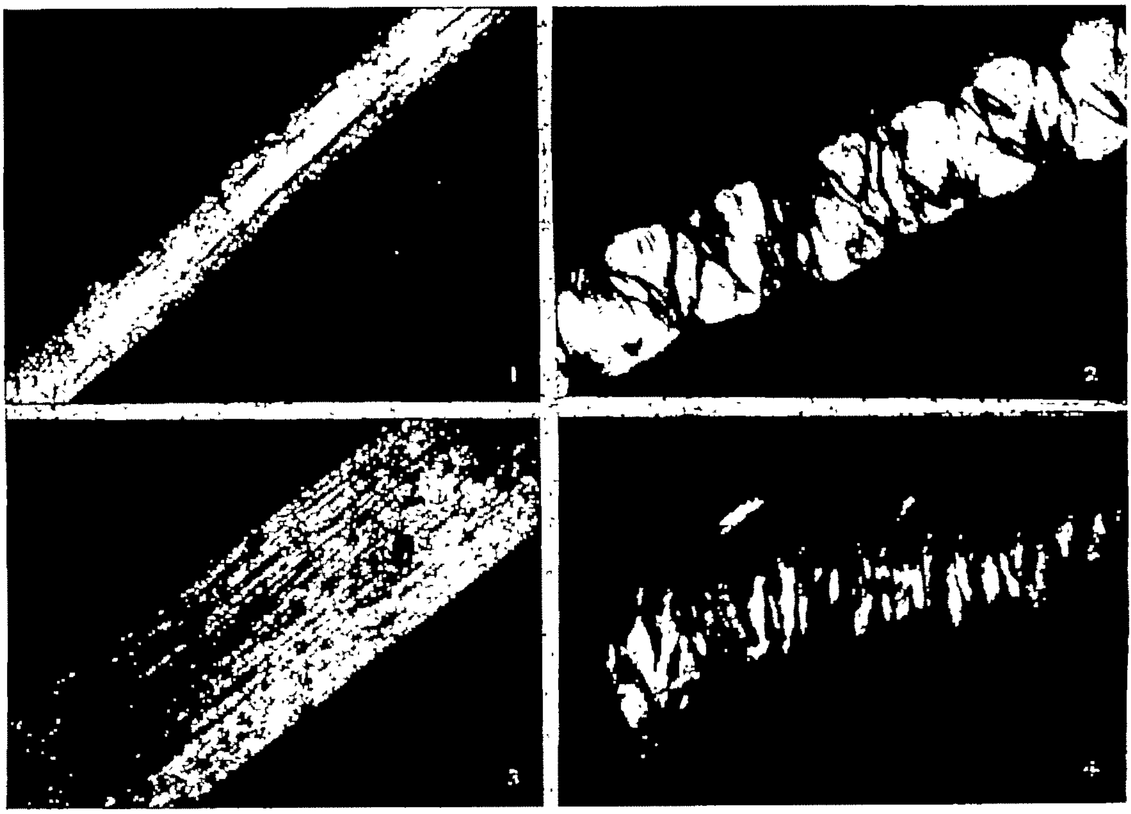
PARTRIDGE[1] reported that tendons from the tail of the rat loaded with small lead shot at above 60° C. in distilled water first shorten and thereafter lengthen, that is, contract and relax.

We have studied this phenomenon in detail by polarization microscopy, and by chemical and enzymical methods using isolated collagen fibres of rat tail tendon. We found that contraction and relaxation can be brought about also without heat at room temperature in concentrated salt solutions such as potassium iodate and potassium mercury-iodate in 40 per cent concentration. Single dry native fibres 1–2 mgm. in weight, 0·10–0·20 mm. in diameter and 5–6 cm. in length were loaded with small lead shot weighing 70–80 mgm. and placed at room temperature (20° C.) in the solutions mentioned above. Contraction starts after 20–30 sec. and ceases in 1–2 min. The fibres shorten to one-third of their length (67 per cent shortening). The relaxation only begins after 20–25 min., and it stops after approximately 60 min., when the fibres have lengthened to 80–85 per cent of their original length. We call this phenomenon observed in concentrated salt solutions at room temperature 'chemical contraction and relaxation'.

We have established that by the heat contraction of collagen fibres performed in water at 67° C. the fibres (as above) contract in 7–10 sec. and relax in 40–60 sec. The shortening is the same as in 40 per cent potassium iodate (67 per cent); the relaxation is 100 per cent. The analyses made by polarization microscopy and with chemical and enzymic methods show that the heat and chemical contraction – relaxation processes are similar to each other.

The native, contracted and relaxed fibres were examined separately in the wet and the dry state. The contracted fibres when wet are elastic, rubber-like, in contrast to the non-expansible native and easily torn relaxed fibres. By polarization microscopy we found that whereas the native fibre is optically homogeneous, in the contracted fibre two optically different phases can be observed: apparently an outer phase with small birefringence and an inner phase with helical structure and strong birefringence. The relaxed fibre is again homogeneous, showing fibrillary structure (Figs. 1, 2 and 3). Imbibition experiments show that in contracted fibre the two phases differ both qualitatively and quantitatively from each other.

The dissolution of protein was examined during the contraction – relaxation processes with larger amounts of collagen fibre. While the fibre is passing from the native to the contracted state, only a small quantity of mucoid[2] is dissolved; but the beginning of relaxation is connected with the dissolution of a larger amount of protein. Having kept the fibres for 20 min. in 40 per cent potassium iodate, relaxation starts; thus 36 per cent of the nitrogen of



Photomicrographs taken with the polarizing microscope. (1) Native fibre, optically homogeneous. (2) Contracted fibre. Outer phase of small birefringence and internal phase of strong birefringence with helical structure (3) Relaxed fibre, swollen, with pronounced fibrillary structure. (4) Contracted fibre after the effect of elastase; the outer phase is dissolved. × 100 the collagen is dissolved, and in 60 min. (complete relaxation) 75 per cent of the nitrogen of collagen goes into solution. By heat relaxation the same dissolution of protein takes place. At 67° C. in 2 min. 14 per cent, in 5 min. 47 per cent and in 10 min. 73 per cent of the nitrogen of the collagen is dissolved. The gross structure of the collagen fibre remains, as if the protein has dissolved only from the inside.

With elastase at pH 10, only 5–10 per cent of the native fibres were dissolved. From the contracted fibre the elastase dissolves the outer phase, which accounts for 15–20 per cent of the entire collagen nitrogen, while the internal phase remains intact. Fig. 4 shows a contracted fibre after treatment with elastase. The relaxed fibres are dissolved with elastase without residue.

The contraction process remains reversible if the fibres, just after contraction, were removed from the solution, washed, stretched and dried in the stretched state. But after relaxation, contraction could no longer be observed.

In a previous experiment, one of us (Banga[2]) showed that during the heat contraction of Achilles tendon a mucoid is dissolved which contains 6–8 per cent of carbohydrate. In those experiments the relaxation is already beginning and the analytical results may have related to the combination of two substances. It is to be noted that in Achilles tendon of cattle the heat contraction – relaxation processes follow much more slowly than in the collagen fibre of rat tail tendon.

Our experiments seem to prove that the collagen fibre is not built up from a single protein but at least of two different protein components. In our experiments the chondroitin sulphuric acid content of the ground-substance which stabilizes the collagen fibre does not play a part in the process of contraction – relaxation. This is shown by the following experiment. We treated the native collagen fibres with a concentrated aqueous solution of hyaluronidase, which dissolves chondroitin sulphuric acid. After treatment for 24 hr., contraction and relaxation took place in the usual way. This indicates that neither of the two proteins described corresponds to chondromucoid.

A paper containing the detailed results of the experiments will be published in the *Acta Morph. Acad. Sci. Hung.*

A Lipid Component of Reticulin

In a previous communication in *Nature*[1], renal cortical reticulin was described as consisting of randomly orientated collagen fibrils embedded in a structureless matrix. X-ray diffraction photographs of these reticulin specimens showed a diffraction pattern quite typical of that of collagen, together with some additional rings; this suggested that the reticulin consisted of collagen together with an unidentified material.

Further studies on the chemical composition of this reticulin, isolated from kidneys as before, indicated that a fat component was present.

The X-ray diffraction pattern of this isolated fat has been compared with that of a series of saturated fatty acids, and the spacings and intensities show close agreement with the series. The precise member of the series present in reticulin was not identified from the diffraction pattern alone, but a melting point over the range 49°–52° C. suggested a mixture of fatty acids, with myristic acid predominating. Analysis by Imperial Chemical Industries, Ltd., using vapour phase chromatography, has given more than 90 per cent myristic acid.

In the X-ray diffraction pattern of reticulin, the broad collagen band at 4·5 A. somewhat masks the bands seen at 4·5 and 3·8 A., which are very intense when the isolated lipid component is examined alone. Outside the classical 2·9 A. collagen band seen in reticulin are other rings at 2·5, 2·35 and 2·2 A.; and these outer rings correspond very closely with those seen with saturated fatty acids.

From a reassessment of the electron microscope results, it is probable that the lipid was present in those regions which were too thick to give clear photographs. The reticulin as isolated was therefore a mixture of three components—collagen, fatty acid and polysaccharide-containing matrix. From the extraction methods used for isolating the reticulin samples, it was clear that the fatty acid was an essential component of the reticulin, and not a contaminant from extra-reticular sources.

Staining Reactions of Elastic Fibres with Special Reference to 'Elastotic Degenerations' in the Human Skin

Part of our research programme is devoted to clarifying various aspects of skin carcinoma in man and in experimental animals. Careful study of the dermal accumulations of morphologically unusual fibrillar material, consistently found in our specimens, and generally referred to by other authors[1] as "an increase in elastic fibres", led us to suspect that these accumulations of unusual fibrils were not, in fact, unmodified elastic fibres. We conducted a systematic survey of the staining reactions of the fibrillar masses in the dermis and in diseased blood vessels, always carefully comparing our findings in the abnormal with those of the elastic and other fibres in apparently healthy human skin, aorta and other vessels.

The unusual clumps of dermal fibres, referred to above, as well as certain fibres which may appear in vessel walls during degenerative vascular diseases, stain with some of the dyes (for example, Weigert's, Verhoeff's, orcein and Gomori's aldehyde-fuchsin, in particular), but not with all the stains which sharply delineate apparently 'normal' elastic fibres. On the other hand, these same fibre clumps may stain with several dyes, or dye-mixtures, which do not stain 'normal' elastic fibres (see Table 1).

The conclusion, therefore, seems to be justified that the accumulations or clumps of morphologically

Table 1. TINCTORIAL REACTIONS OF ELASTIC FIBRES IN HEALTHY DERMIS AND ARTERIES COMPARED WITH 'ELASTOTICALLY DEGENERATED' FIBRES

Stain	'Normal' elastic fibres—dermis or arteries	'Elastotically degenerated' fibres—dermis or arteries
Orcein	Deep red-brown	Pale to deep reddish-brown
Verhoeff's	Dark blue-black	Pale to dark blue-black
Weigert's	Deep purple-blue	Deep purple-blue (+ eosinophilic 'granules')
Gomori's aldehyde-fuchsin	Deep red-purple	Deep red-purple to pale red
Periodic acid-Schiff	Red borders	Irregular red 'pools' and pink fibre borders
Iron hæmatoxylin	Grey, black or brown	Grey to jet-black fibres, rods and 'pools'
Safranin water-blue (Unna)	Pink to red	Pink to deep red
Van Gieson	Yellow with thin red fibre outlines	Yellow with irregular red 'granules'
Wilder's reticulum and basic fuchsin	Red fibre 'cores' with thin black outlines	Irregular coarse granular and fine black fibres
*Ponceau 2*R*—light green	Bright pink-red	Irregular blotchy 'grey' with red and yellow patches
*H. and E.	Pale pink	Pale blue-grey + pink 'granules' and threads
*Toluidine blue	Colourless to pale-blue	Deep blue-green coarse fibres and 'granules'
*Mallory's triple	Orange to pink	Completely chromophobic with scattered orange or blue 'granules'
*Mallory's phosphotungstic acid hæmatoxylin	Bright purple 'coat' with orange 'core'	Pale orange with occasional purple threads
*Rinehart–Abul Haj†	Pale yellow 'cores' with bluish-green outlines	Dirty pale green with scattered blue 'pools'

* Implies stains providing clearly distinguishable tinctorial differences between 'true' elastic fibres and 'elastotically degenerated' fibrillar aggregations.

† Modified Hale's method for acid mucopolysaccharides (ref. 4).

abnormal fibres, particularly in the dermis, while simulating that "increase in elastic fibres" described by modern authors, cannot be regarded as being constituted of unaltered elastic fibres, either on morphological or on tinctorial criteria. We suggest the name 'elastotically degenerated' fibres for these masses, since they are morphologically and tinctorially distinguishable from normal elastic and collagen fibres, although they stain with the generally used elastic stains.

These elastotically degenerated fibres seem to be derived primarily from alterations in the composition of preformed collagen, or, perhaps, from disturbances in metabolic processes during the formation of normal reticular, collagen or elastic fibres. The former possibility, concerning the origin of 'elastotically degenerated' fibres, is supported by our recently recorded finding[2] that, some time after the grafting of trypsin-treated auto- or homo-dermal tissue in man, numerous plaques or even extensive beds of 'elastotically degenerated' tissue can usually be found in the dermis of the host area. These fibre masses may have been derived from the original collagen of the graft. Alternatively, the grafted dermal collagen may have induced a change in the metabolism of the connective tissue in the host site, resulting in the deposition of new fibres, which were 'elastotically degenerated' *ab initio*—a possibility in conformity with the latter of the above two suggestions. Stages in the formation of these abnormal fibres, in dermis, can be defined on the basis of tinctorial reactions with the aid of the above-mentioned dyes. The final product of such elastotically degenerated fibres can be sharply distinguished from an increase in 'true' elastic fibres and from 'normal' collagen fibres.

Our findings also indicate that the generally accredited standard histological methods for demonstrating elastic fibres cannot be relied on to stain only 'normal' elastic fibres. This latter view is in conformity with that expressed by Astbury *et al.*[3] from their combined histological and electron-microscopic studies of normal and abnormal human dermis.

The expenses incurred during this study were defrayed primarily by a generous grant from the Schlesinger Organization, South Africa. Literature was made available, in part, through the Florence Powell Cancer Research Library Grant and through the kind assistance of Mrs. B. H. Robinow. We also acknowledge the technical assistance of Patricia R. Low.

Secretion of Aldosterone and Corticosterone by the Rat Adrenal

A STUDY has been made of the nature and regulation of rat adrenal steroid secretion. The adrenal-vein blood of rats was collected, extracted and chromatographed by the method of Bush[1,2]. Corticosterone was detected and estimated by the soda-fluorescence reaction[1]. Mineralocorticoid activity was estimated by the biological method of Simpson and Tait[3].

A potent mineralocorticoid was detected in the zone of the paper chromatogram which would include aldosterone[4,5]. In concentrates of this zone there was a substance which had the same R_F and soda-fluorescence reaction as aldosterone and was present in an amount appropriate to the observed biological activity. The activity of this zone has been tentatively identified with aldosterone.

Intact rats, subjected to the surgical stress of collection of adrenal effluent, secreted aldosterone equivalent to about 45 μgm. of deoxycorticosterone acetate, and 150 μgm. corticosterone per adrenal/kgm./hr., with a ratio of 0·30 : 1. Treatment with deoxycorticosterone acetate for seven days (2 mgm. per day), or feeding a potassium-deficient diet for four weeks, reduced the secretion of aldosterone by more than 90 per cent without altering the corticosterone secretion. The ratio was lowered to 0·014 : 1 by the potassium-deficient diet, and to 0·044 : 1 by the deoxycorticosterone acetate treatment.

Untreated hypophysectomized rats, examined at two, seven or fourteen days after operation, secreted an average of 7·8 μgm. deoxycorticosterone acetate equivalent of aldosterone and 2 μgm. of corticosterone, per adrenal/kgm./hr., with a ratio of 3·65 : 1. In hypophysectomized rats two days after operation, acute treatment with corticotropin (homogeneous by ion-exchange chromatography[5]; 1 μgm. at the start, and 0·5 μgm. during collection) raised the rates of secretion of both steroids. There was a greater proportional increase in the corticosterone, and the quantities of both steroids secreted were not significantly different from those in intact rats. A similar result was obtained when hypophysectomized rats received a daily dose of 200 μgm. corticotropin for seven or fourteen days after operation, and the adrenal effluent was then collected with acute corticotropin stimulation.

Hypophysectomized rats kept for seven days without corticotropin maintenance gave a different response to acute treatment with corticotropin. The aldosterone secretion was increased to the equivalent of 50 μgm. of deoxycorticosterone acetate, comparable with the values in intact rats, but the corticosterone only to 9 μgm. per adrenal/kgm./hr. The ratio of the secretions, 5·4 : 1, remained typical of untreated, hypophysectomized rats.

In the only experiment on this point, daily treatment of hypophysectomized rats with both deoxycorticosterone acetate and corticotropin depressed aldosterone secretion to a level similar to that of the intact rats treated with the former, without influencing the secretion of corticosterone. This experiment suggests that changes in the secretion of aldosterone following treatment with deoxycorticosterone acetate, and possibly those following changes in electrolyte balance, can occur in the absence of the pituitary.

These studies show that a potent mineralocorticoid, probably aldosterone, is secreted by the rat adrenal; this observation is analogous to those of Simpson *et al.* with the dog[6] and the monkey[7]. The results provide direct support for the indirectly based view of Swann[8] and later workers[9], according to which mineralocorticoid secretion in the rat can vary independently of glucocorticoid secretion and can be influenced by extra-pituitary factors. However, our experiments show clearly that the simultaneous secretion of both aldosterone and corticosterone can be induced by corticotropin. It is also noteworthy that secretion of both steroids still occurs in the hypophysectomized rat without corticotropin.

We wish to point out that these results do not provide any evidence relating to the proposition that the zona glomerulosa of the rat is specifically associated with secretion of aldosterone.

A detailed account of these studies will be presented elsewhere. This work was largely financed by a grant from the Nuffield Foundation to Prof. F. G. Young and was under his general direction.

Development of Pain-producing Substance in Human Plasma

WE have previously reported[1-3] that inflammatory exudates and fresh plasma produce: (i) pain when applied to the exposed base of a cantharidin blister in man, and (ii) contraction of the isolated rat uterus. Since we find these two actions to run in parallel, we assume that they are due to the same agent, which we term 'pain-producing substance'. When an inflammatory exudate is collected in a glass syringe, this substance is not at first detectable, but develops within 2–5 min. The same is true of whole blood, with or without anticoagulant.

The development of pain-producing substance in plasma can be prevented by avoiding contact with glass or metal during the process of collection and separation, as follows. Blood is withdrawn into a silicone-coated needle and syringe and rapidly transferred through polythene tubing immersed in ice to cooled polythene centrifuge tubes containing heparin (40 units/mL., final concentration). The blood is immediately centrifuged at 22,000 rev./min. for 4 min., after which the upper half of the separated plasma is removed and placed in fresh polythene tubes in ice. This plasma, in which there are no white cells and practically no platelets (< 50/c.mm.), contains little or no detectable quantity of the pain-producing substance when kept in polythene tubes for up to two hours, but activity develops within a few minutes after the plasma is transferred to a glass tube. This activity reaches a peak within 10 min. and decays to 1/10–1/20 of peak value within an hour. The decay of the substance in plasma is delayed at 0° C. and prevented by deep-freezing.

The same effects are observed when sodium citrate (3 mgm./mL., final concentration) is used as anticoagulant. In the absence of anticoagulant, plasma kept in polythene tubes still fails to develop the pain-producing substance; but when it is transferred to glass tubes activity appears and clotting occurs.

Biological actions of the pain-producing substance. (i) Active plasma applied to an exposed blister base produces delayed and prolonged pain[1]. It does not cause itching, flare or wheal. Our previous report[1] that plasma did not produce pain referred to tests performed from one to three hours after collection of blood, when the pain-producing substance would have decayed.

(ii) It causes contraction of the isolated rat uterus. At peak activity, 0·01 mL. of plasma (in a 30-mL. bath) may produce maximal uterine contraction. This action is not antagonized by atropine or dihydroergotamine. This preparation is particularly suitable for routine assays of the pain-producing substance.

(iii) It produces delayed slow contraction of the guinea pig ileum and also stimulates the rabbit jejunum. It lowers blood pressure in the cat and rat.

Chemical properties of the pain-producing substance. (i) Pressure ultrafiltration at 0° C. of active plasma through a 'Cellophane' membrane yields protein-free filtrates containing the pain-producing substance; their activity rarely exceeds one-fifth of average peak activity in plasma. Pain-producing substance produced in this way is stable for several hours at 20° C. There are, however, certain minor differences between the biological actions of ultrafiltrates and their parent plasmas, perhaps due to the presence of modifying substances in the latter.

(ii) Freeze-dried samples of active plasma or ultrafiltrate are active; such material can be used to study solubility characteristics of the substance.

(iii) The substance is soluble in water, glacial acetic acid, hot methyl alcohol, 90 per cent ethyl alcohol and 90 per cent acetone. It is insoluble in ether, absolute ethyl alcohol and anhydrous acetone.

(iv) It is precipitated with the proteins when alcohol or acetone (10 or 20 vol.) is added to active plasma in the cold.

(v) It is adsorbed by charcoal and cellulose powder, but not by barium sulphate. It is completely removed from ultrafiltrates by cation exchangers (hydrogen form), and partially removed by anion exchangers (hydroxyl form).

(vi) Pain-producing substance from ultrafiltrates is stable on boiling in $N/3$ hydrochloric acid for 10 min., but is largely destroyed on boiling in $N/3$ sodium hydroxide for 10 min.

(vii) It is rapidly inactivated by plasma.

(viii) The substance is inactivated by chymotrypsin (Armour). Trypsin (Armour) has a much weaker action, and crystalline pepsin has no effect.

It has not yet been possible to isolate the pain-producing substance in a pure form. Its biological and chemical properties resemble those of bradykinin, a polypeptide prepared by Rocha e Silva *et al.*[4,5] by the action of trypsin or *Bothrops jararaca* venom on plasma α-globulins.

A sample of bradykinin (activity 10 units/mgm.) in a concentration of 10 μgm./ml. produced pain like that due to our pain-producing substance; 100 μgm./ml. also produced itching, flare and wheal. Bradykinin also stimulates smooth muscle and lowers blood pressure[4]. It is rapidly inactivated by plasma and by chymotrypsin, but not by trypsin[5]. On Rocha e Silva's estimate[5] that such bradykinin preparations contain about 0·5 per cent of a pure polypeptide of molecular weight 5,000–10,000, our most active plasmas contain pain-producing substance in a concentration equivalent to 1 μgm./ml. of the pure bradykinin.

Certain other biologically active polypeptides, for example, angiotonin (hypertensin), substance P, leucotaxine, oxytocin and vasopressin, also produce both cutaneous pain and contraction of smooth muscle; but studies on relative potency, and some differences of action, have shown that our pain-producing substance is not identical with any of these. Nevertheless, the evidence suggests that it is a polypeptide. It can be readily distinguished from 5-hydroxytryptamine (serotonin)[2,6].

The processes concerned with the appearance of the pain-producing substance in cell-free plasma are obscure, but the failure to develop activity in contact with polythene and the time-course of development in contact with glass are strikingly reminiscent of the processes of blood clotting. However, heparin and sodium citrate do not prevent the activation of plasma by glass. The rapid decay of the substance in plasma, coupled with its much greater stability in protein-free solutions, suggest an enzyme-catalysed destruction.

The role of the pain-producing substance in the production of pathological pain is being studied. We suggest that development of the substance might occur when plasma escapes from capillaries and makes contact with damaged tissues as, for example, in burns.

We are grateful to Dr. M. Rocha e Silva and to Dr. H. O. Schild for bradykinin; to Dr. A. C. Corcoran and Dr. F. Merlin Bumpus for lyophilized angiotonin; to Dr. B. Pernow for substance P; to Dr. W. G. Spector for leucotaxine; and to Prof. C. J. O. R. Morris for the loan of the ultrafiltration apparatus. We should like to thank Mr. B. J. Stevens for valuable technical assistance.

Estimation of the Survival-Rate of Anopheline Mosquitoes in Nature

THE daily survival-rates of *Anopheles gambiae* and *A. funestus* in two areas of tropical Africa have recently been estimated from the ratio of their sporozoite-rates immediately on capture and those recorded after keeping wild-caught specimens alive for the duration of the extrinsic cycle of the predominant malaria parasite[1,2]. This method naturally involves considerable time for the dissection and keeping alive of significant numbers of mosquitoes.

A more direct method of determining the age-composition of wild-caught populations, based on changes in the size of the ampulla of the oviduct with ovarian development and oviposition[3], has now been evolved. By this method the proportion of a given population which is parous (M) can be determined and the survival-rate per day (p) calculated from the expression[4], $p^n = M$, where n is the number of days between emergence of adult and first oviposition.

Table 1. AMPULLA DIAMETERS OF COLONY *A. gambiae* MEASURED IN DISTILLED WATER

Stomach and ovary conditions	No. of mosquitoes examined	Ampulla diameters in microns: Mean	Standard error	Median
Nulliparous females				
Never fed—ovary stage I	145	124	1·8	120
Fed once, but no ovarian development beyond stage II	187	168	2·2	160
Fed once or twice with ovarian development to stage III	72	204	3·1	200
Fed once or twice and gravid—ovary stage V	85	242	3·2	240
Parous females				
Laid once after one or two feeds—ovary stage II	62	265	3·8	264
Laid once, fed again and developing the second batch of eggs—ovary stage III	44	258	4·3	256
Laid twice—ovary stage II	25	279	4·7	280

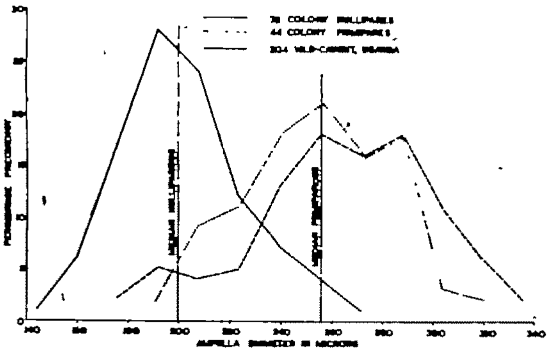

Fig. 1. Frequency distribution of ampulla diameters of colony and wild-caught *A. gambiae* with stage III ovaries

Evidence now exists[1-3] that in the case of *A. gambiae* the time from emergence to first oviposition is five days in the hotter parts of Africa, composed of: (*a*) the first feed, 24 hr. after emergence, but without ovarian development beyond ovary stage II; (*b*) the second feed, two days after the first; (*c*) two days elapsing from the second feed to the maturation of the eggs and oviposition.

Extensive studies of colony *A. gambiae* have shown increases in diameter of the ampulla of the oviduct with feeding, ovarian development and oviposition (Table 1); these were most marked when dissection was carried out in distilled water. At the same time, considerable variation in ampulla diameter was found to occur in females in the same stage of ovarian development in the same gonotrophic cycle and, as a result, a considerable overlap in measurements between mosquitoes in the same stage of ovarian development but in successive gonotrophic cycles (Fig. 1). However, the smallest diameter recorded for a particular ovary stage in primiparous females was very seldom less than the median diameter recorded in nulliparous females in the same stage. Thus it is considered justifiable, when dealing with wild-caught mosquitoes of any one ovary stage, to take those showing ampullæ of less diameter than the median recorded in nulliparous females of the same ovary stage as half the nulliparous females.

The proportions parous in each of the ovary stages II–V (females with stage I ovaries were obviously nulliparous) have been estimated in this way in three series of wild-caught *A. gambiae* from the two areas of Africa where the immediate and delayed sporozoite-rates were estimated (two of the series were dissected over the same periods as the latter), and the survival-rates were found to be almost identical by the two different methods (Table 2).

In practice it is considered simpler, instead of dissecting mosquitoes in all ovary stages, to restrict dissections to those of the commonest ovary stage found in Nature by the usual methods of mosquito capture. In the hotter parts of Africa the commonest ovarian stage in daytime house-resting *A. gambiae* is stage III. In this species the first stage III ovary is normally reached on the fourth day after emergence, and the gonotrophic cycle at temperatures of 23·3° C. and higher is two days[6]. Thus the proportion of mosquitoes at this ovarian stage which is nulliparous is:

$$\frac{p^4}{p^4 + p^6 + p^8 + p^{10} \ldots p^\infty}$$

$$= p^4 \bigg/ \frac{p^4}{1 - p^2}$$

$$= 1 - p^2;$$

from which p^2 = 1 − proportion nulliparous
= proportion parous.

Therefore, $p = \sqrt{\text{proportion parous.}}$

Thus the survival-rate equals the square root of the proportion parous if the gonotrophic cycle occupies two days (the cube root if it occupies three days).

In the three series of wild-caught *A. gambiae* already mentioned, the survival-rates calculated from stage III females only were:

Tanganyika, 1952	0·91
Tanganyika, 1953	0·91
Uganda	0·93

Thus the method in its simplest form requires:

(1) Analysis on colony-bred mosquitoes of the median ampulla measurement, and its range, for nulliparous and parous mosquitoes in the same stage of ovarian development (preferably stage III); this has been done for *A. gambiae*.

(2) A knowledge of the period occupied by the gonotrophic cycle.

(3) Capture of wild mosquitoes and derivation by the method given of the proportions nulliparous and parous; it is thought that this can be estimated with considerable accuracy providing it is established that none, or very few, of the ampulla diameters of parous mosquitoes fall below the median of nulliparous ones.

(4) Derivation from this of the daily survival-rate; this depends on an assumption that the population is relatively static in composition and needs correction by observation over several consecutive days.

Influence of Ribonuclease on the Division of Amphibian Eggs

Thomas, Rostand and Grégoire[1] observed that the puncture with a needle which had been dipped in a relatively pure solution of ribonuclease inhibits the development of undivided frog's eggs and prevents cellular division. They also showed that no such effect is obtained with deoxyribonuclease, nor with pepsin or trypsin used under the same conditions. We thought it of interest to repeat these observations with highly purified enzymatic preparations, taking advantage of the fact that only reduced ribonuclease has enzymatic activity[2].

Fertilized amphibian eggs (*Rana fusca*, *Axolotl*, *Pleurodeles*) were injected with reduced or oxidized ribonuclease; urease was used as a control. Reduced ribonuclease was prepared as previously described[2]; oxidized ribonuclease was prepared by the action of hydrogen peroxide on the reduced form[3].

Of all enzymes tried, only reduced ribonuclease was active; division of the injected blastomere was inhibited with concentrations of the order of 10^{-12} mol. per egg. Using higher concentrations, the neighbouring blastomeres are also affected. Neither oxidized ribonuclease nor urease (—SH form) showed visible effects, even when 10^{6} times more concentrated. Thus, only the enzymatically active reduced form of ribonuclease inhibits embryonic development, and the conditions of preparation of the enzymes exclude all possibility of contamination.

These results confirm those of Thomas, Rostand and Grégoire, and emphasize the need for the —SH groups in the enzyme. As the injection of concentrations higher than 10^{-10} mol. in one of the blastomeres of segmenting embryos inhibits the development of the neighbouring blastomeres, we thought this might be an indication that the enzyme is capable of crossing cellular membranes. We therefore placed the eggs of pleurodeles in solutions of reduced and oxidized ribonuclease of different concentrations. In these conditions, embryonic development is completely stopped by concentrations of reduced enzyme greater than or equal to 100 µgm./ml. Oxidized ribonuclease is also completely without effect on segmentation (Figs. 1, 2 and 3).

In order to verify if the enzyme really penetrates into the egg, we prepared radioactive oxidized and reduced ribonuclease with radioactive iodine[4] and we followed its diffusion by radioautography[5]. Sections show a zone where radioactivity appears in the embryo and which extends progressively from the animal pole. Simultaneously a zone of increased basophily appears in the radioactive region, but only when reduced ribonuclease was used. This zone appears to correspond to an increase in ribonucleic acid synthesis, as seems indicated by preliminary determinations on egg homogenates. This synthesis of ribonucleic acid induced *in vivo* by reduced ribonuclease is probably the first step in its antimitotic action. This action seems to be related to a modification of the process by which the cytoplasm assumed a gel form and which interferes with the normal formation of the segmentation furrows.

Summarizing, ribonuclease in its reduced form is a very potent antimitotic agent. Both oxidized and reduced enzymes diffuse easily through the cellular membranes of amphibian eggs. Reduced ribonuclease seems to induce a synthesis of ribonucleic acid during its diffusion, and this substance is probably related to the inhibition of segmentation.

Breeding of the Tree Shrew

A colony of tree shrews, *Tupaia glis* (Diard), has been maintained at the University of Malaya for the past nineteen months, specimens having been obtained both from the Federation of Malaya and from Thailand. A total of fifty-five living animals has been received; the colony at the time of writing includes thirteen males and fourteen females. After heavy mortality in the early stages of the work, the death-rate dropped to a point where most of those animals surviving the first three months tend to live for at least a year.

Most of the animals are kept in compound cages consisting of six three-foot cubical units, but some are kept in a large outdoor cage of 1,280 cu. ft. capacity. The large cage is heavily planted with shrubs and vines.

The natural diet of *Tupaia* apparently includes a preponderance of insects, supplemented by soft fruits. The present diet includes fruits such as banana and papaya, and an 'insect substitute' mixture containing high-protein cereal, beef extract, honey, fresh eggs, powdered milk, dog biscuits for roughage, cod liver oil, vitamin E, calcium lactate and salt.

Extreme variations in weight obscure evidence of pregnancy by weight records until the last two weeks of pregnancy. Delicate abdominal palpation has often proved satisfactory in indicating pregnancy at an early stage. The animals are highly nervous, however and require delicate handling.

In no case has it been possible to keep two male tree shrews in the same cage. A male and one or more non-pregnant females live in reasonable harmony, a female being dominant despite he smaller size. Pregnancy has produced marked anti-social aggressiveness in the females observed

An aggressive attitude towards another individual, once begun, seems to remain fixed, and will lead to a fatal feud unless the animals are separated. Fighting occurs just as frequently in the large as in the small cages.

Copulation, first observed in January of this year, occurred with increasing frequency during February and March and declined through April and May. Nineteen out of twenty-four females were observed to copulate at least once; eight became palpably pregnant, some individuals more than once, with thirteen pregnancies in all. All but one of the pregnant females either aborted or killed and ate their young the night they were born. The exception (*Tf*39) has given birth twice; the first pair of young was neglected and was found dead and trampled in the nest box litter four days after birth; the second pair was eaten by the mother on the third day. *Tf*39 became pregnant a third time but aborted or resorbed the embryos at about half term.

There is no indication of male sterility, all males appearing sexually vigorous. The females appear to suffer from some factor or factors antipathetic to reproduction manifested by refusal to mate, sterility, spontaneous abortion, litter killing, and neglect of the young. In no case has there been any record of enlargement of mammary glands in pregnant females; the single case of neglect of the young may have been due to milk failure.

The gestation period for *Tupaia glis*, as indicated by the records to date, is between 46 and 50 days. Of six pregnancies for which the number of embryos is certain, there were twins in five cases and a single young in the sixth. (These records include autopsies on three pregnant newly captured females which were received dead.)

Female *Tf*39 showed what I interpret as post partum heat; she achieved a fertile mating between 48 and 72 hr. after parturition.

Observations to date indicate that male sexual aggressiveness is stimulated by female secretions and that the female goes through a socio-psychological pattern similar to that of heat in non-primates.

Cases of intra-uterine bleeding suggestive of menstruation are being investigated at present.

Acknowledgment is due to the Institute for Medical Research, Kuala Lumpur, Malaya, and to the U.S. Army Medical Research Unit in South-East Asia for supply of Malayan specimens and for financial aid in obtaining animals from Thailand respectively. Both bodies are interested in breeding of tree shrews as laboratory hosts of primate virus diseases. The study is proceeding, and I would welcome communication from interested workers.

Note added in proof, Sept. 29. A litter of two born on August 20 is now being weaned.

Attempts at Nitrogen Fixation *In vitro*

THE low activation energies generally associated with free-radical reactions have prompted several workers to explain the high velocity of various biological processes[1,2], including nitrogen fixation[3,4], by mechanisms involving free radicals. Burris's fixation mechanism[3] postulated an enzyme–hydrogen peroxide complex and reduction or oxidation of molecular nitrogen by the free radical $A_2.H^{\cdot}$ or $A_2.(OH)^{\cdot}$, respectively, in the latter case producing $N_2(OH)_2$. Pethica *et al.*[4] suggested that nitrogenase, like catalase[5] and methæmoglobin[6], functions by way of a ferrous–ferric couple activated (as in Fenton's reagent) by hydrogen peroxide, which they regarded as an intermediate in respiration. The link between respiration and fixation could be hydroxyl radicals which reacted with nitrogen to form $N_2(OH)_2$.

Attempts were made, using the isotopic technique, to detect *in vitro* fixation by cell-free extracts from *Azotobacter vinelandii* in the presence of free hydrogen and hydroxyl radicals. Extracts from vigorous cultures were prepared by grinding centrifuged and washed cells with powdered 'Pyrex' glass and phosphate buffer solution (*p*H 7·0) at – 2° C.; the paste was spun out and the supernatant used immediately. An atmosphere of oxygen and heavy nitrogen was circulated by means of the apparatus previously described[7,8] through various solutions in the culture flasks for five hours. In case oxygen gas, some constituent of the medium[8], or free radicals were necessary before nitrogenase could function, these were supplied, singly and together. Hydrogen and hydroxyl radicals, which would according to Pethica be supplied *in vivo* by the respiratory system, were generated *in vitro* by reaction between *M* ferrous sulphate and *M*/2 hydrogen peroxide (inhibitor-free), one drop of each being added every five seconds throughout the experiment.

No shift in the abundance ratios of the atmosphere was observed in any experiment, nor were any gas samples obtained from the various solutions by the Kjeldahl digestion process[3]. In five hours, the equivalent of eighty litres of labelled atmosphere, containing 26·0 atom per cent excess nitrogen-15, passed through each solution, so that it is clear that no fixation of nitrogen is possible under the conditions described. It may be that nitrogenase does not survive the extraction, or must be augmented in some way not at present understood. It is of interest that nitrogen can be fixed in aqueous solution by an electric discharge. Campardou[9] gives the equations:

$$N_2 + 2H_2O \rightarrow NH_4NO_2$$
$$NH_4NO_2 + \tfrac{1}{2}O_2 \rightarrow NH_4NO_3$$

and observes that the net reaction uses nitrogen and oxygen in the exact proportion in which they dissolve in water at one atmosphere pressure. However, the results above, together with failure[8,10] to demonstrate the importance of compounds of formula $N_2(OH)_2$ (which is common to the different free radical postulates), constitute strong experimental evidence against such postulates.

A Quantitative Biological Test Sensitive to Low Doses of Ionizing Radiations

THE important linear dose-effect relationship which is observed in the induction of mutations with ionizing radiations and which has been verified down to 25 r. has not been satisfactorily investigated below this value[1].

Owing to the existence of the 'induction' phenomenon, lysogenic bacteria may be used to demonstrate this relationship within a wide range of doses, including doses as low as 1 rep. The virus in such bacteria is in a masked state, the prophage, which is included in the genetic pattern. Its induction may be considered as a lethal mutation. That some radiations 'induce' the development of phage in lysogenic bacteria was discovered by Lwoff, Siminovitch and Kjelgaard[2] using ultra-violet radiations (2537 A.) and was later shown by Latarjet[3] to occur with X-rays. A bacterium 'induced' with X-rays bursts after a latent period, the length of which depends on physiological conditions, and liberates an average of 100–200 virus particles into the medium. By determining the number of free phages in an induced culture, it is possible to determine how many bacteria have been induced.

The strain utilized here is the lysogenic *E. coli* *K*.12(λ) cultured in 'Difco' tryptone broth. After induction with X-rays, the latent period is 55 min.; that is, after this delay, the first bacteria burst. However, the majority lyse between the 65th and 80th minutes. Both the latent period and the burst size (average number of phage particles liberated per bacterium) are independent of the dose.

In a non-irradiated growing culture of *K*.12(λ) one finds, owing to spontaneous bursts, about one phage per 200 bacteria. This figure corresponds to about 10^{-3} to 10^{-4} spontaneously 'induced' bacteria per generation time. After induction by X-rays, the number of free virus particles increases proportionally to the number of induced bacteria. By measuring the increase in frequency of free phage in the medium, the number of induced bacteria may be estimated.

In an irradiated sample the total number of free phages, N_r, is equal to the sum of the phages produced by induction, N_i, and those arising spontaneously, N_s. For the most accurate determination of N_r it is necessary to have N_s as small as possible. This condition is automatically fulfilled for high doses (more than 50 rep.), but for low doses N_s must be diminished. This may be done without appreciably affecting N_i owing to the fact that the large majority of N_i appear between the 65th and the 80th minute. N_s may be inhibited by adding anti-λ serum before the 65th minute and then suppressing the action of the serum by dilution.

The following experimental technique is used. Samples of a culture of *E. coli* *K*.12(λ) in tryptone broth containing 2 × 10^8 bacteria/c.c. are diluted tenfold in broth at 0° C. and irradiated. Aliquots of 1 c.c. are taken and kept at 37° for 55 min. At the end of this time, 0·05 c.c. of anti-λ serum is added. At this concentration the serum inactivates 90 per cent of a phage suspension in 5 min. at 37°. The serum is allowed to act for 10 min. and then diluted 100-fold in broth in order to stop its action.

The samples are then incubated for 10 min. at 37°. During this time N_s in the control increases to one-tenth of the initial value, while nearly all the phages arising from induction are liberated. At the 75th minute the bacteria are killed by the chloroform technique[4] and the free phages are titrated. Contrary to *T*2, λ is partly inactivated by this treatment, but since inactivation is the same for every sample the results are unaffected. The titration of the free phage is made using *K*.12S/Str. (streptomycin-resistant) as the indicator strain in the presence of 200 γ of streptomycin to prevent contamination. The plaques are counted after 18 hr. incubation at 37°.

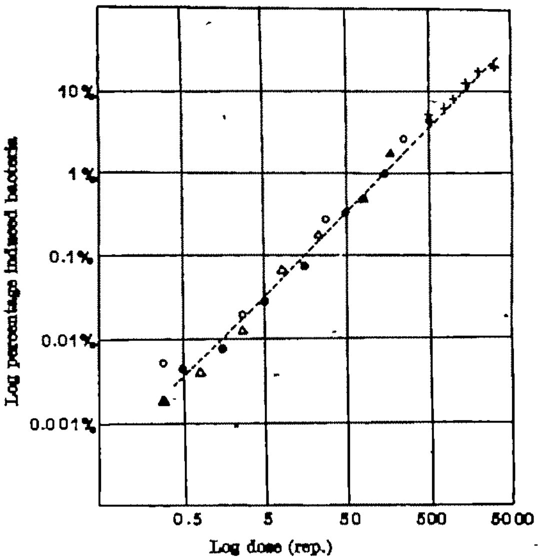

Fig. 1

The source of X-rays is a Holweck tube with a molybdenum target which operates at 37 kV. giving an average wave-length of 0·9 A.

With doses greater than 500 rep. the technique described above (free phage technique) is unnecessary. If the bacteria are plated immediately after irradiation (direct method) each induced bacterium gives one plaque and the percentage of induction may be calculated directly.

In the free phage technique the relationship between the ratio N_i/N_s and the radiation dosage is linear. The slope of this straight line is the same as that of the straight line obtained by the direct method which relates percentage of induced bacteria to dose (see Fig. 1). The two straight lines are brought into conjunction by determining for the same dose (500 rep.) the percentage induction by the direct method and the ratio N_i/N_s by the free phage method on the same sample. This procedure gives a constant which is added to log N_i/N_s so that results below 500 rep. may be expressed as percentages. Since in Fig. 1 the abscissæ and ordinates are on the same scale, it may be concluded that the number of induced bacteria is directly proportional to the dose and that, consequently, induction is a single-hit process.

In Table 1 are given the data used to calculate N_i/N_s for the experiment represented in Fig. 1 by circles. A dose of 1·5 rep. produces a significant increase in the number of the plaques.

Table 1

Doses		0·5	1·5	5	15	50	150	500
N_r		1,225	1,556	4,180	9,070	33,100	114,000	430,000
N_s	697							
N_i/N_s		0·75	1·23	4·85	11·96	46·28	161·8	613

On extrapolating the straight line it can be seen that 100 per cent induction corresponds to a dose of about 10,000 rep. On the basis of the target theory, the diameter of the target for induction is therefore of the order of 100 mμ.

The same doses expressed in rep. given as γ-rays of radium or as X-rays of wave-length 0·9 A. produce the same frequency of induction. By using both X- and γ-rays the inducing effect of radiations was found to be independent of intensity over a range of 10^4. The irradiated bacteria and the control may be kept at 0° C. for several hours without affecting the results of the experiment. This permits the study of ionizing radiations produced at some distances from the laboratory. After 24 hr., however, the sensitivity of the test is lower.

The sensitivity of the above test depends on the inactivating power of the antiserum. Since λ is unfortunately a poor antigen, other lysogenic systems are being investigated.

In addition it should be noted that the sensitivity of this method was found to be too low to detect any effect of cosmic rays at sea-level or any naturally occurring ionizing radiation.

I thank Dr. R. Latarjet for his criticisms and suggestions and Miss R. Vayne for technical assistance.

Paramagnetic Resonance in Carbonaceous Solids

FOLLOWING the discovery[1,2] of a paramagnetic resonance absorption of high intensity, and narrow width, in charcoals and other low-temperature carbons, a systematic survey of different coal and carbonized coal samples has been undertaken, to determine what factors affect the magnitude of the absorption. The samples were prepared at Leatherhead and the measurements have been made at Southampton using frequencies of 24,000 Mc./s., 9,000 Mc./s. and 40 Mc./s.

The first effect studied was the variation in intensity of the paramagnetic absorption signal with carbonizing temperature, and the results are shown in Fig. 1. Two series of carbonized coals were used, and both gave very similar variations, having a marked maximum at a carbonizing temperature of c. 550° C., and then falling sharply to zero. This variation of signal strength with carbonizing temperature has also been found in other specimens, and it seems to be a general feature that the paramagnetic resonance absorption is destroyed once the carbon has been heated above c. 650° C. These results seem to confirm the previous suggestion[3] that this type of absorption is not due to conduction electrons such as those found in graphite[3], but rather to unpaired electrons associated with 'broken bonds' or 'free radicals'. We suggest that heating above 650° C. enables these bonds to join with those from neighbouring carbon atoms, the absorption signal being therefore considerably reduced.

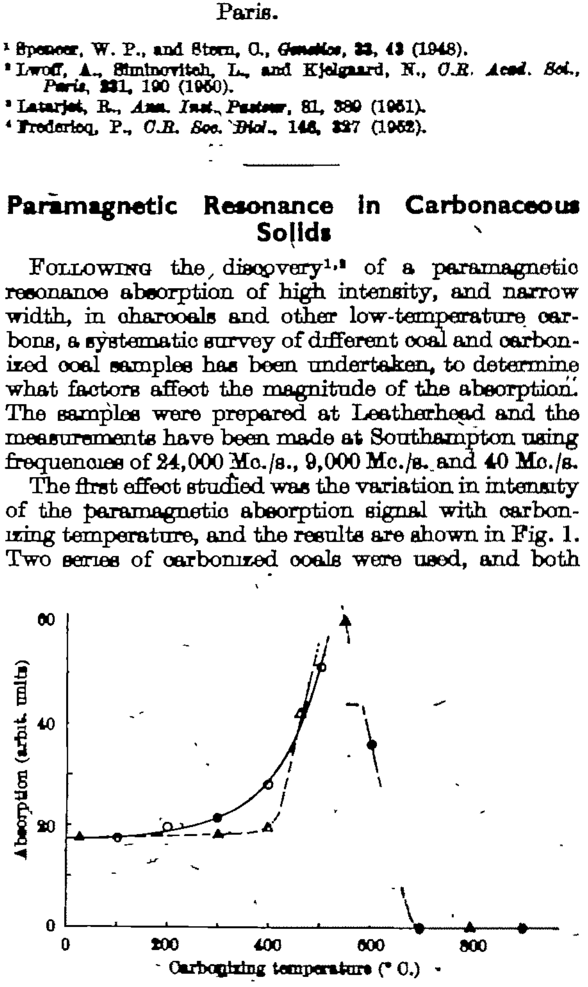

Fig. 1

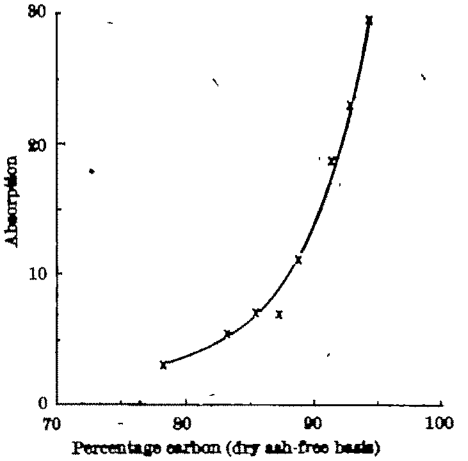

Fig. 2. Absorption of 30 units = 2·5 × 10^{19} free radicals/gm.

The line width and spectroscopic splitting factor remained constant over the whole range of carbonizing temperatures, having values of 8 ± 2 gauss and 2·0030 ± 0·0003 respectively. A width of 7 ± 1 gauss was still obtained at 40 Mc./s., which is in striking contrast to the value of 0·1 gauss obtained by Henning *et al.*[4] on graphites at these frequencies, again suggesting that this is an entirely different mechanism from that associated with the conduction electrons. It would appear that variations in width observed in other low-temperature carbons[3] are therefore due to special effects, such as gas adsorption.

An estimate of the number of free radicals present in the carbon was obtained by comparing the intensity of absorption with that from 50 μgm. of diphenyl trinitrophenyl hydrazyl; the results indicated that there are about 3 × 10^{19} free radicals/gm. in carbons showing the highest absorption (that is, one free radical per 1,600 carbon atoms).

The second effect studied was the variation of absorption intensity of raw coal with its percentage carbon content (rank). These results are shown in Fig. 2. A very sharp increase in the intensity of paramagnetic absorption is observed in coals of rank exceeding 80 per cent carbon content (dry ash-free basis), the intensity at 94 per cent being seven times that at 80 per cent. If the absorption intensity is plotted against the percentage of volatile matter in the coal, an alternative, though less reliable, measure of its rank or maturity, a straight line is obtained.

Since submitting this letter for publication, the work of J. Uebersfeld, A. Étienne and J. Combrisson on a similar subject has been reported (*Nature*, 174, 614; 1954).

Microwave Spectrum of Methyl-Cyanoacetylene

THOUGH methyl-cyanoacetylene (methyl-propiolnitrile) is a substance of some interest structurally, its preparation has not apparently been described. With the object of studying the microwave spectrum of this substance, we have prepared it by the method used for obtaining higher alkyl-cyanoacetylenes by Grignard and Courtot[1] and Curran and Wenzke[2]. The Grignard reagent, $H_3CCCMgBr$, was treated with cyanogen chloride and a moderate yield of methyl-cyanoacetylene isolated as a colourless, low-melting solid of sweet, penetrating aromatic odour. The best sample obtained to date, by vacuum fractionation, has melting point 16° C., boiling point 101·5° C. (754 mm.) and $n_D^{20} = 1 \cdot 4342$, but we regard these values as preliminary ones, pending a closer study of possible traces of impurities.

The microwave pure-rotation spectrum of the substance suffices to identify the molecule with certainty. The spectrum is that of a strictly symmetric-top molecule of moment of inertia compatible only with the expected linear arrangement of the nitrogen and carbon atoms on the figure axis. Quadrupole coupling hyperfine structure is also observed, the splitting being that expected for a nitrogen-14 atom located on the figure axis in the group $—C \equiv N$; the *iso*cyanide grouping is thus excluded, since it is not expected to give rise to resolvable quadrupole coupling[3]. Measurements have been made on the $J = 5 \rightarrow 6$, $8 \rightarrow 9$ and $10 \rightarrow 11$ transitions, and spectroscopic constants are derived as follows: $B_0 = 2{,}065 \cdot 73$ Mc./s., $D_{JK} = 19 \cdot 8$ kc./s., $D_J = c.\ 0 \cdot 1$ kc./s. and eqQ of $^{14}N = -4 \cdot 4 \pm 0 \cdot 5$ Mc./s. Absorption lines due to molecules in excited bending vibrational states are also observed in the manner expected for this molecule.

The moment of inertia, I_B, derived from B_0 is $406 \cdot 20 \times 10^{-40}$ gm.cm.^{2}, and is in good agreement with the most probable structural parameters. Thus the structure

$$\overset{1\cdot458}{H_3C—C} \equiv \overset{1\cdot379}{C—C} \equiv N \quad (C \equiv C: 1\cdot203,\ C \equiv N: 1\cdot157)$$

(distances in A.), with $d_{CH} = 1 \cdot 10$ A. and the HCH angle 108° 30′, is in accord with I_B. These parameters are close to those found for analogous bonds in cyanoacetylene[4] and methylacetylene[5]. Methyl-cyanoacetylene has a structure very similar to that of penta-1 : 3-diyne[6], and the values of the distortion constants are very similar for the two molecules.

Further measurements on the fine structure of the spectrum are planned, and it is hoped to evaluate the coupling constant more precisely. Work is also in progress on D_3CCCCN, and we hope later to detect spectra of other isotopic combinations and to determine further details of the structure. We are also investigating the possibility of exchange reactions between the hydrogen atoms and deuterium oxide.

Details will be given in a full report to be published elsewhere.

Thunderstorms and Sporadic *E* Ionization of the Ionosphere

IN the course of the ionospheric observations carried out at Calcutta (lat. 22° 33′ N., long. 88° 21′ E.) for more than two decades, it had always been found that sporadic *E* ionization (E_s) is greatly increased during the occurrence of thunderstorms. In view of the persistence of the phenomenon, it was thought worth while to make a close study of the increase of E_s ionization during the occurrence of severe thunderstorms of the squall type, known as 'nor'westers', which are a special feature of the weather of this part of India (Bengal) in the pre-monsoon months March–May. During these thunderstorms the wind generally blows from a north-westerly direction with velocity often exceeding 50 miles/hr. The thunderstorms are invariably accompanied by lightning discharges.

Sporadic *E* ionization during ten such squalls occurring in the months April–May of 1953 and 1954 has been studied. As the squall was seen to be approaching—indicated by the appearance of the towering cumulo-nimbus clouds—special observation on E_s (besides the usual routine ones) was started and continued until the squall passed over. The observation consisted in gradually increasing the frequency of the transmitter and noting the frequency (fE_s) at which the E_s echo disappeared. The E_s's were distinguished by the characteristic fluctuation of the echoes and the simultaneous appearance of the F_2 echoes. The observations were repeated every four minutes during the progress of the squall. Figs. 1 and 2 depict graphically the results of the study for two typical cases. (The meteorological data in the figures regarding the progress of the squall—start, highest gust and end—and the atmospheric pressure variations were obtained from the Meteorological Office, Alipore, six miles south of the ionosphere station.)

It will be seen that with the approach of the squall there is sudden appearance of intense sporadic *E* ionization over the observing station. fE_s attains values as high as 10 Mc./s., as compared with the

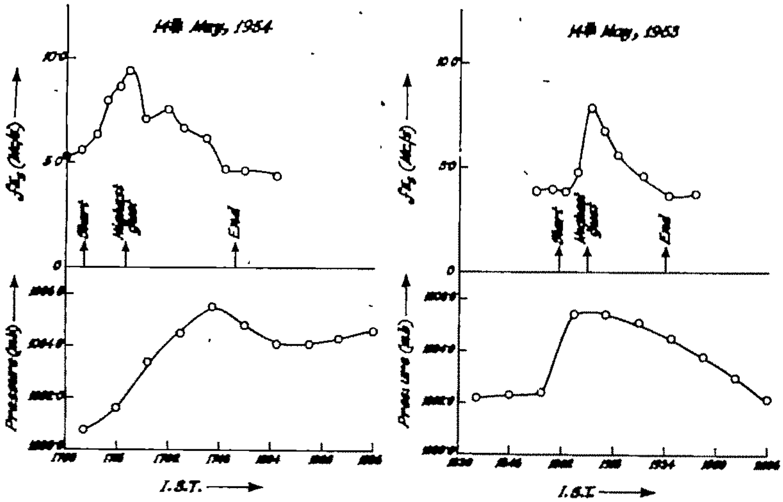

Fig. 1

Fig. 2

Figs. 1 and 2. Increase in the intensity of sporadic *E* ionization (measured by the penetration frequency fE_s) during the incidence of 'nor'wester' type of severe thunderstorms at Calcutta. The lower curves show the variation of atmospheric pressure during the progress of the storms

average no-storm value of 3·5–5 Mc./s. at this station. It is also to be noted that the development of the sporadic *E* ionization is such that it attains a maximum soon after the arrival of the squall overhead and decays gradually as the squall moves past the observing station.

The above results strongly suggest that one at least of the causes of sporadic *E* ionization, the origin of which is still insufficiently understood, is associated with thunderstorms.

The investigations described above form part of the programme of the Radio Research Committee of the Council of Scientific and Industrial Research, Government of India. One of us (M. R. K.) is a research assistant under the Council. We acknowledge the help of Mr. A. K. Saha, research assistant, in making the observations.

Reactions of Molten Salts with Layer-Lattice Silicates

In a study of the reaction of molten salts with layer-lattice silicates, it has been found that treatment of muscovite less than 5 μ equivalent spherical diameter in size with molten lithium nitrate removes a large portion of the potassium from the mica, and lithium is fixed in a not readily exchangeable manner. When saturated with barium and glycerol-solvated, the material gives a 001 spacing of 17·8 A., the basal spacing for glycerol montmorillonoids. The intensity of the 17·8 A. line with respect to the 10 A. mica line varies with the muscovite/lithium nitrate ratio and the length of treatment. The muscovite was obtained by fractionation of delamica, a finely divided muscovite separated from Cornish china clay and containing a small amount of kaolinite.

As an example of the action of molten lithium nitrate on muscovite, the chemical composition of the treated and untreated material from one experiment is shown in Table 1. The 1–0·2 equivalent spherical diameter fraction of muscovite was heated with 60 parts by weight of lithium nitrate at 300° C. for 18 hr., washed free of excess salt and saturated with calcium by seven washings with 1 *N* calcium chloride, and total potassium and lithium determined with an Eel flame photometer.

Theoretically, muscovite should contain 250 milliequivalents of potassium per 100 gm. The negative charge equivalent to this presumably arises from substitution of Al^{3+} for Si^{4+} in tetrahedral co-ordination. If potassium is replaced by cation exchange or the negative charge on the layer decreased internally by penetration of lithium into the structure, the summation of milliequivalents of potassium, lithium and cation exchange capacity should be constant. The equivalences by Table 1 are a general feature of all treatments analysed. The experimentally determined cation exchange capacity is in good agreement with the difference 250 − $\Sigma K^+,Li^+$. These equivalences suggest the following mechanism: lithium replaces potassium, then enters the lattice and reduces the charge on the lattice, which renders it expandable.

The X-ray diffraction pattern of a glycerol-solvated specimen of the untreated muscovite showed no trace of any expanding material. When the lithium-treated muscovite was saturated with barium and glycerol-solvated, it showed a rational series of reflexions corresponding to a d_{001} of 17·8 A. on X-ray analysis.

Removal of potassium from muscovite by molten lithium nitrate proceeded quite rapidly in the case of the 1–0·2 μ fraction until the concentration of potassium in the melt reached a value of approximately 0·05 *N*. Treatment of muscovite with a melt of lithium nitrate having a potassium concentration of 0·05 *N* resulted in almost complete inhibition of the reaction.

Other dioctahedral micas, including an illite from Fithian, Illinois, a micaceous sub-soil clay on basement Carboniferous sandstone from North Wales, and paragonite reacted in a manner similar to the muscovite. Biotite, a trioctahedral mica, was not expanded by treatment with molten lithium nitrate.

Hofmann and Klemen[1], in explaining the irreversible loss of surface on heating of lithium-montmorillonite, suggested that lithium ions migrated into the vacant octahedral positions with a consequent neutralization of charge. The present work

Table 1. CHEMICAL COMPOSITION OF TREATED AND UNTREATED MUSCOVITE OF 1–0·2 μ EQUIVALENT SPHERICAL DIAMETER

	Potassium ions	Lithium ions	Cation exchange capacity	$\Sigma K^+,Li^+$, cation exchange capacity
	(milliequivalents per 100 gm.)			
Untreated	223	15	15	253
Treated	63	94	92	249

shows the lithium ions to be very firmly held by the dioctahedral layer silicates on treatment with molten lithium nitrate, and although it does not show that they enter octahedral co-ordination, it is unlikely that the lithium could be fixed between the layers or on accessible surfaces in such readily expanding material.

A more detailed account of this work will be published elsewhere.

Grateful acknowledgment is made to the British Museum (Natural History) for gifts of minerals. I wish to thank George Brown for his encouragement and general assistance and Dr. D. M. C. MacEwan for his interest and the invitation to work in the X-Ray Section of the Rothamsted Pedology Department. The investigation was undertaken while on sabbatical leave from the Purdue University Agronomy Department and during the tenure of a National Research Council (U.S.A.) Postdoctoral Fellowship.

Conductivity induced in Polystyrene by X-Rays

A long time-constant of recovery for the conductivity induced by X-rays in a polystyrene-insulated condenser was observed by one of us (F. T. F.) in 1942[1]. We have recently made further measurements on polystyrene, using the d.c. amplifier technique with the insulating specimen in an evacuated chamber, as previously described[2,3]. The dependence upon temperature and dose-rate of the induced conductivity both during and after irradiation have been investigated.

These experiments have confirmed the long time-constant, which is comparable with those observed in polythene[3] and polytetrafluorethylene[4]. The magnitude of the induced current, however, is smaller than in the two latter materials, being in fact of the same order as that in 'Perspex' or some types of amber.

Dose-rate dependence. In the relationship between induced current i and dose-rate R,

$$i \propto R^{\Delta}, \qquad (1)$$

we find $\Delta = 0{\cdot}6 \pm 0{\cdot}1$ for polystyrene over the range $R = 2$–64 r./min., and between 20° C. and 110° C. Using Rose's model of photoconducting insulators[5], this value of Δ leads us to postulate an exponential distribution of trapping-levels below the conduction band. A consequence of this model is that when Δ is close to $\frac{1}{2}$, the variation of Δ with temperature should be large enough to be observed. This is in fact found to be so, Δ having the higher values at the lower temperatures, as in the case of polytetrafluorethylene[4].

Temperature dependence. Fig. 1 shows the graphs of log (conductivity) of polystyrene plotted against the reciprocal of absolute temperature. The resulting straight lines are of slope proportional to the activation energy, according to the general formula

$$\sigma = \sigma_0 \exp\,(-W/kT). \qquad (2)$$

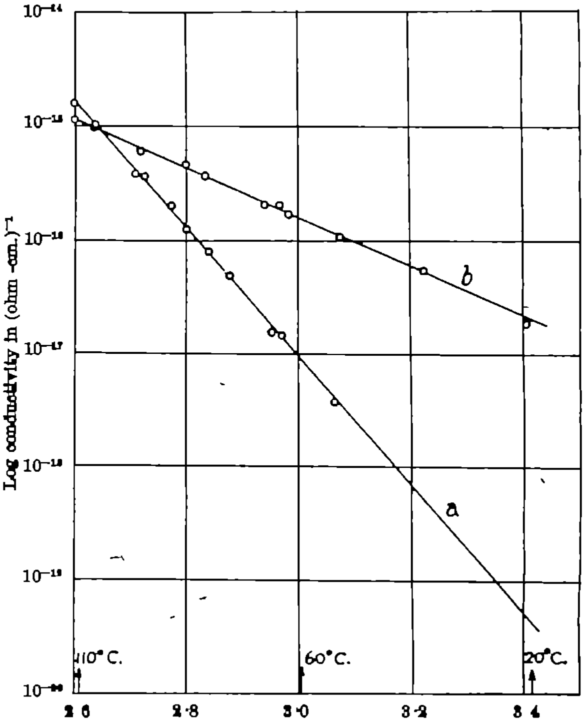

Fig. 1

In the case of static conductivity (that is, no incident radiation; Fig. 1*a*), $W = 1{\cdot}2$ eV. For the equilibrium induced conductivity under X-irradiation (Fig. 1*b*) at $R = 7$ r./min., the slope corresponds to $W = 0{\cdot}44$ eV.

From the latter graph it can be seen that the induced current increases by a factor of 60 between 300° K. and 400° K. The corresponding increase predicted using the model of an exponential distribution of traps is by a factor of 80, if we assume a value of $N_0 = 10^{19}$ for the number of available energy-levels in the lowest part of the conduction band a few kT wide. The agreement is fairly satisfactory, and shows that a slightly lower value of N_0 would give better agreement, as in the case of polythene and polytetrafluorethylene.

Decay of induced current. The time-constant of decay varies slowly with temperature, showing the same general features that we have described for polythene and polytetrafluorethylene: at temperatures below 70° C. the current falls at first more rapidly, but after a few minutes more slowly than at higher temperatures, so that complete decay takes longer at the lower temperatures. The current remaining after a few minutes is proportional to 1/time, as for polythene and polytetrafluorethylene. The time-constant decreases with increasing dose-rate, as expected, and the relationship appears to be reciprocal.

The magnitude of the time-constant is large, being even greater than for polytetrafluorethylene (for which $\Delta = 0{\cdot}63$), and considerably longer than for polythene ($\Delta = 0{\cdot}8$). The following table summarizes the results:

Temperature	Dose-rate	Time to fall to 10 per cent	Time to fall to 1 per cent
100° C.	7 r./min.	1 hr	6 hr.
20° C.	7 r./min.	¼ hr.	12 hr.

These recovery curves are in good agreement with the earlier results[1] of one of us (F. T. F.).

The magnitude of the induced current accords well with the results of Armistead, Pennock and Mead[6], and of Coleman and Bohm[7], if equation (1) is used to extrapolate the present measurements to the higher dose-rates used by them.

Anomalies in Osmotic Pressure Measurements

In the course of a study of the molecular weights of coal-tar pitch fractions, we have observed unusual anomalies with two samples in benzene solution. A large number of fractions have been examined in benzene and in other solvents using modified Zimm–Meyerson osmometers fitted with specially prepared polyvinyl alcohol membranes[1] of the lowest possible permeability. We and other workers[2] have found samples of average molecular weight as low as 250 to be retained by the membranes, and nearly all our samples have followed van't Hoff's law almost exactly. As the full results of the investigation are being published elsewhere, attention is now directed only to the behaviour of two fractions produced by molecular distillation of that part of a coke-oven tar pitch which is insoluble in petroleum ether of boiling range 100–120° C. but soluble in benzene.

These two samples are believed to consist predominantly of condensed polycyclic aromatic hydrocarbons and to contain also limited quantities of compounds containing oxygen, nitrogen or sulphur in the ring structure or oxygen in phenolic form. Both have a number average molecular weight of about 400. The anomalous behaviour is a marked reduction of the reduced osmotic pressure, when measured at 25° C. in benzene solution, with increasing concentration. In both instances the actual osmotic pressure passed through a maximum and fell again as the concentration was raised. One of the samples was found to yield no detectable pressure at all at a concentration of 0·065 gm. per 100 gm. solvent. The other sample was examined at each of several temperatures in benzene and at 30° C. in nitrobenzene, the results being shown in Fig. 1. The phenomenon tends to disappear at elevated temperatures and does not occur at all in nitrobenzene solution.

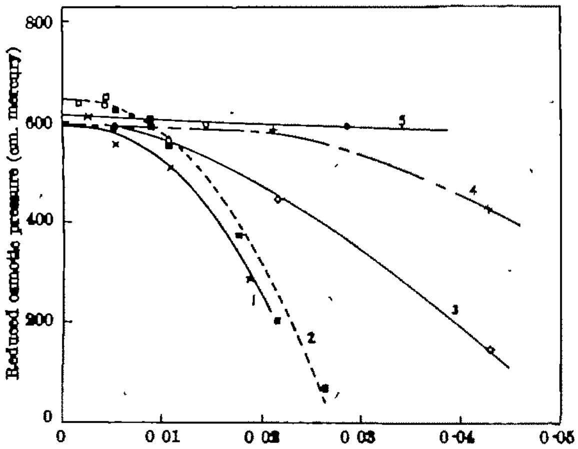

Fig. 1. Reduced osmotic pressure curves for pitch fractions. Curves 1–4, in benzene at 20°, 25°, 30°, 40° C. respectively. Curve 5, in nitrobenzene at 30° C.

At first sight this behaviour seems to be most readily explained by assuming association of the solute molecules in a weak solvent, and the effect of raising the temperature and of changing to the stronger polar solvent seems to support this view. That association should occur to the extent indicated by the results, however, and at so low a concentration, is difficult to imagine.

Structural Changes in Boiling Solutions of Sugar with Reference to Chromatography of Carbohydrates

The sensitivity of the chromatographic method in detecting sugars has made possible a greater appreciation of the labile character of many monosaccharides, and has emphasized the significance, in quantitative work, of degradation in sugar solutions at the boil[1] and of accelerated epimerization attributable to trace alkalis in chromatographic paper[2]. It does not seem to be so fully appreciated, however, that structural changes in sugar solutions can occur during heating for periods comparable with those frequently used in polysaccharide hydrolyses, and that such changes might give rise to misinterpretation of the results of qualitative paper-chromatography studies.

The effect referred to may be illustrated by the chromatograms reproduced in Fig. 1, which were obtained by applying the appropriate syrups to the paper without heat-drying, developing with butanol/acetic acid/water solvent, and spraying with aniline hydrogen phthalate. The hydrolysate of the water-soluble fraction of chlorite-treated *Urena lobata* fibre, after neutralization and concentration to a syrup at 50° C., was applied, without heating, along a line on a sheet of filter-paper. A spot of the syrup was used to indicate the positions of the separated fractions in the main chromatogram (Fig. 1,*a*). Half the section of the paper which contained the rhamnose fraction of the hydrolysate was extracted with distilled water in a micro-Soxhlet apparatus, and the solution in the flask was maintained at the boil for 12 hr., a period in excess of that required for complete extraction, yet considerably less than many hydrolysis times quoted in the literature. On chromatographic development the concentrated solution yielded not only a spot corresponding to rhamnose but also another spot for a sugar with an R_G value approximating to that of xylose (Fig. 1,*b*). The other half of the section of the paper, with the remainder of

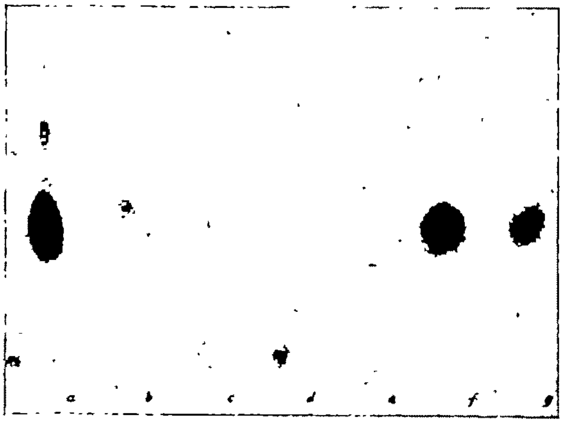

Fig. 1. Chromatograms illustrating the effect of heating sugar solutions. (a) Hydrolysate from *Urena lobata*; (b) rhamnose fraction of the hydrolysate after boiling; (c) rhamnose fraction from the hydrolysate eluted with cold water; (d) pure rhamnose solution after boiling; (e) pure rhamnose; (f) pure xylose solution after boiling; (g) pure xylose

the rhamnose separated out from the main hydrolysate, was eluted with cold distilled water, and the resultant chromatogram (Fig. 1,c), obtained as usual, showed only the single spot corresponding to rhamnose. Thus it would appear that the rhamnose isolated from the fibre hydrolysate was uncontaminated by other sugars, and that epimerization or other structural change had occurred by and during the heating of the aqueous solution. It seemed scarcely feasible that alkaline conditions could have arisen either from the glassware, which was of well-used 'Pyrex', or from the filter-paper, in view of the acidity of the solvent used. Confirmation that structural transformation occurs on heating rhamnose in non-alkaline solution was obtained by refluxing a solution of chromatographically pure rhamnose (Fig. 1,d) in distilled water for 12 hr., during which period the pH of the solution fell to a value of 3·9 (Fig. 1,e).

The conversions occurring are not confined to the methyl pentose, since xylose solution, which yielded a single spot on a chromatogram (Fig. 1,g), showed additional spots after boiling for 12 hr. (Fig. 1,f).

Effect of Chelating Agents on Heavy Metal Catalysis

In a recent communication, Pirie and Van Heyningen[1] have reported "a case where a chelating agent accelerated the oxidation of a substance (glutathione), which it was intended to preserve in the reduced state"[1]. The object of the chelating agent was "the removal of metals", traces of which would presumably catalyse the oxidation. Since chelating agents are being generally used for this purpose, it seems worth while emphasizing that the metal chelate complexes formed are not necessarily without catalytic activity. Thus 1 : 10 phenanthroline, $\alpha\alpha'$di-pyridyl and $\alpha\alpha'\alpha''$tripyridyl increase the iron-catalysed rate of decomposition of hydrogen peroxide by as much as one hundred-fold[2], and certain hæmoprotein complexes of iron are well known as catalysts in biological systems.

We are studying the effect of chelating agents on the metal-catalysed autoxidation of *cyclo*hexene. Only in the case of copper has the metal chelate complex been found to be catalytically inactive. In the case of iron, the formation of the chelate complex greatly increased the rate of the reaction. Approximate results are quoted in the table for the reaction at 60° C. in the presence and absence of 2 gm. mol. of NN′disalicylidene ethylene diamine per gm. mol. of the metal heptoate.

Metal, initial valency state and concentration	Extent of oxidation after 60 min. reaction (gm. oxygen/kgm. *cyclo*hexene)	
	No chelating agent	Disalicylidene ethylene diamine present
Cu^{II} 50 p.p.m.	13	0·12
Fe^{III} 500 p.p.m.	1·3	c. 50
Mn^{II} 49·5 p.p.m.	21*	25
Co^{II} 49·1 p.p.m.	27	36*
Metals absent	0·12	0·12

* Durations of these reactions are taken as 60 min. from the termination of the induction periods.

The formation of the chelate complex has little effect on the manganese-catalysed reaction. The kinetic characters of the two cobalt-catalysed reactions are completely different, however. In the absence of disalicylidene ethylene diamine the rate decreases, but in its presence the rate increases during the initial course of the reaction. The effect of a chelating agent sequestering copper but 'vivating' iron has also been established by us for the autoxidation of *cyclo*hexene in the presence of NN′di*cyclo*hexyldithiooxamide. Further, we have observed a similar phenomenon for the autoxidation of sodium sulphite in aqueous solution, thus indicating that it is by no means confined to non-aqueous media.

The foregoing results show that not only metal ions but also covalently bound metals can be effective catalysts for free-radical chain-reactions. The fact that copper catalysis is prevented by chelation may result from the special condition that cuprous–cupric transitions probably involve large free energies of activation when the metal is chelated. Both cuprous and cupric copper have a normal co-ordination number of four, but the former requires a tetrahedral and the latter a planar disposition. Iron, however, will co-ordinate octahedrally in both valency states. Moreover, a quadridentate chelating agent may sterically prevent reaction in the case of a metal with a normal co-ordination number of four if the electron transfer mechanism requires the reacting molecule to enter the co-ordination shell of the metal. The study of hexadentate chelating agents for metals with a maximum co-ordination number of six should throw further light on these possibilities. Work is continuing in this direction.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Principal (with appropriate agricultural qualifications, together with experience in teaching, administration and practical farming) of the Yorkshire Institute of Agriculture, Askham Bryan, near York—The Chief Education Officer, County Hall, Wakefield (October 28).

Scientists (with a first- or good second-class honours degree in physics, engineering, mathematics or statistics, and experience in field, laboratory or operational research), in the Field Investigation Group, to carry out field work at collieries—National Coal Board, Establishments (Personnel), Hobart House, London, S.W.1, quoting TT/852 (October 30).

Lecturer (graduate in chemical engineering or graduate in chemistry with postgraduate training and/or experience in chemical engineering) in Chemical Engineering—The Principal, Manchester Municipal College of Technology, Manchester (November 1).

Research Fellows (2) (one with at least a second-class honours degree in physics, chemical or mechanical engineering, and the other with at least a second-class honours degree in mechanical engineering or physics) in the Department of Textile Industries—The Registrar, The University, Leeds (November 1).

Assistant Lecturer (with a university degree in engineering or equivalent, and preferably with some industrial experience) in General Engineering Subjects—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (November 2).

Assistant Lecturer in Pure Mathematics—The Registrar, The University, Sheffield (November 6).

Chemical Engineer or Chemist (with a good honours degree in chemistry or A.M.I.Chem.E., and with previous industrial experience), at the Divisional Laboratory, National Coal Board, Edgbaston, Birmingham, for investigations into the treatment and disposal of mine water effluents—The Divisional Establishment Officer, National Coal Board, Himley Hall, Dudley, Worcestershire (November 6).

Biometrician (with a good degree in mathematical statistics, and a wide experience in the design and analysis of field experiments in all branches of agricultural and animal husbandry research); a Fisheries Officer (graduate in natural science, and preferably with specialization in zoology, and with subsidiary knowledge of physiology and chemistry); a Dairy Officer (graduate in dairying or agriculture, and with experience in the administration of milk recording schemes); a Systematic Botanist (graduate in botany and preferably with experience in herbarium work); and an Animal Husbandry Officer (graduate in agriculture with specialization in animal husbandry), in the Department of Research and Specialist Services, Federal Ministry of Agriculture, Federation of Rhodesia and Nyasaland—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (November 10).

Technical Officer, Grade II (with good general training in chemistry, preferably up to degree standard, and experience in fuel technology and fuel analysis) in the Coal Survey Laboratory, Leeds—National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/856 (November 10).

Assistant Lecturer (Botany), and a Demonstrator (Zoology) in the Biology Department—The Registrar, University College of North Staffordshire, Keele, Staffs (November 13).

Cereal Technician (with a sound knowledge of wheats and milling technique, and City and Guilds of London certificate or equivalent qualifications) at the Agricultural Research Institute, New South Wales Department of Agriculture, Wagga, Australia, to be fully responsible for the preparation, appraisal and milling of wheat on Allis Chalmers test mill, and maintenance of plant—The Agent General for New South Wales, 56 Strand, London, W.C.2 (November 15).

Lecturer in Civil Engineering at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, November 15).

Lecturer (with a university degree in mechanical engineering) in Mechanical Engineering at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 22).

Lecturer in Applied and Industrial Chemistry at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 25) (Additional copy to The Registrar, University of Cape Town, Private Bag, Rondebosch, C.P., South Africa (November 30)).

Lecturer (with good experience in different types of educational posts, and preferably with ability to specialize in methods in teaching science) in Education at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Hong Kong, November 30).

Professor (with a higher degree, teaching experience at university level and with research experience in at least one of the more important fields of psychology) of Psychology, at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, November 30).

Agricultural Economist (graduate in economics and/or agriculture, and with some postgraduate experience in agricultural economics), in the Department of Agricultural Economics, School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

Assistant (graduate in metallurgy, chemistry or physics, and preferably with foreign language knowledge), for abstracting, translating, literature searching, indexing and editorial work—The Secretary, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1.

Chemists or Engineers (with an honours degree in science or engineering, or Corporate Membership of a recognized professional institution, and with varied scientific experience in industry or a research establishment) at Risley, to serve in a headquarters section whose function is the co-ordination and control of a group of laboratories—The United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 688.

Electrical Engineers and Physicists (with a first- or second-class honours degree or equivalent in physics or light electrical engineering) at the Ministry of Supply Radar Research Establishment, Malvern, Worcs, for research and development work on radio and electronic equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.267/54A.

Engineer or Chemist, Grade I (with an honours degree in engineering or science or Corporate Membership of a recognized professional institution, and with wide and varied engineering or scientific experience, and preferably with experience in programme planning, cost control, staff management, etc.), to take charge of a headquarters section responsible for co-ordinating activities of a group of research and development laboratories—United Kingdom Atomic Energy

Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 686.

ENGINEERS and PHYSICISTS, Senior Scientific Officer and Scientific Officer grades (with an appropriate first- or second-class honours degree or equivalent high professional attainments), in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire areas, and in Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 246/52A.

GEOLOGIST (with a degree in science with geology as a major subject, or equivalent, and preferably with experience of economic geology) IN THE MINES DEPARTMENT of South Australia—The Agent General and Trade Commissioner for South Australia, South Australia House, Marble Arch, London, W.1.

JUNIOR INVESTIGATOR (Research Officer grade) (with a degree in metallurgy or equivalent qualifications), to undertake research work on the welding of aluminium alloys and special materials; and a LABORATORY ASSISTANT (Research Assistant grade), to undertake metallographic work and testing as a member of a research team—The Secretary, British Welding Research Association, 29 Park Crescent, London, W.1.

KEEPER (with practical experience in a herbarium and ability to organize and direct technical staff, and preferably with a science degree and a fundamental knowledge of taxonomic botany) OF THE HERBARIUM (Botanic Garden), Adelaide, South Australia—The Agent General and Trade Commissioner for South Australia, South Australia House, Marble Arch, London, W.1.

MASTER or MISTRESS TO TEACH BIOLOGY throughout the school to university entrance standard—The Headmaster, Keswick School, School House, Keswick.

MICROBIOLOGIST (preferably with medical qualifications and some experience of clinical bacteriology and virus work), for research on aetiology of non-specific urethritis—Prof. A. A. Miles, Lister Institute, Chelsea Bridge Road, London, S.W.1.

ORGANIC CHEMISTS (Ph.D. or equivalent experience) to continue research on the degradation of carbohydrates—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester.

PHOTOGRAPHIC TECHNICIAN (with good training in photographic methods, and preferably with some experience in medical work)—The Secretary, Royal Free Hospital School of Medicine, Hunter Street, London, W.C.1.

PHYSICIST (with a good honours degree and preferably some research experience), to undertake research on the shrinkage and dimensional stability of fabrics—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester.

SCIENTIFIC ASSISTANT (with a university degree, a knowledge of at least two European languages and ability to write clear, concise English), for duties which include abstracting world scientific literature on animal breeding, genetics and production—The Director, Commonwealth Bureau of Animal Breeding and Genetics, King's Buildings, Edinburgh 9.

SENIOR EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with higher school certificate (science) or equivalent), to assist in a chemical engineering branch, in the compilation of detailed flowsheets, design calculations, and plant specifications, required for the engineering design branch for new chemical plant and equipment—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 519/WGE/2.

TECHNICIAN IN THE DEPARTMENT OF CHEMICAL ENGINEERING to assist in preparation of Co-enzyme "A"—The Secretary, University College, Gower Street, London, W.C.1, quoting Chem.Eng./2.

UTILIZATION OF RESEARCH IN THE BRITISH COMMONWEALTH

A RESOLUTION passed at the British Commonwealth Scientific Official Conference in 1946 recommended the preparation of a report on the methods for promoting the application of research carried out under government auspices which had proved successful in the countries of the Commonwealth. This arose out of the realization that what was of first importance for Great Britain in particular was not the general expansion of research but the more effective utilization of existing knowledge. Following Sir Henry Tizard's emphasis on the point in his presidential address to the British Association in 1948, the problem has been regarded as one of increasing urgency and has been considered both by the Parliamentary and Scientific Committee and the Advisory Council on Scientific Policy. It has also received some comment in the reports of the productivity teams which visited the United States under the auspices of the Anglo-American Productivity Council.

In spite of this, a draft report in implementation of the recommendation of the Scientific Official Conference was only presented to the British Commonwealth Scientific Conference held in Australia early in 1952, instead of in December 1947, as originally recommended. The draft report was endorsed by the Conference, and it has now been brought up to date to the end of 1953 and published[*]; it also includes a brief reference to the survey of the relations between industry and science in the Greater Manchester area carried out by the Manchester Joint Research Council, so far as it bears on the problem, issued only in April last. All but forty of the two hundred pages of a well-produced volume are occupied by a series of factual accounts of the means at present used in the United Kingdom, in Canada, in Australia, in New Zealand, in South Africa, in India, in Ceylon and in Southern Rhodesia for securing the rapid translation of research results into practice. A further appendix describes methods used in the United States by the Tennessee Valley Authority, the Bureau of Agricultural and Industrial Chemistry of the United States Department of Agriculture and the Research Corporation and University Research Foundations.

These factual accounts are clearly presented and, on the whole, are adequate; though, seeing that most of the information was reasonably accessible, the time-lag seems inexplicable. Where the book is inadequate is in the three chapters reviewing the methods by which the results of scientific research are normally communicated, supplementary methods, and obstacles to the use of information. These chapters fail so completely to provide the critical analysis required that the conclusions which follow likewise fail to get to the heart of the problem; indeed, the book makes practically no contribution to the question what are the forces and motives which retard or stimulate commercial development. It takes us no further than the discussion on the subject nearly three years ago at the International Symposium on the Organization of Scientific Research sponsored by the Department of Scientific and Industrial Research. Far more searching and relevant to present needs are the comments in the Comparative Study of Applied Research in Europe, the United States and Canada, published as Vol. 1 of the report of three Technical Assistance Missions of the Organization for European Economic Co-operation the substance of which, with two related volumes, was noticed in *Nature* of October 23, p. 778.

---

[*] The Application of Results of Research. Compiled and Edited by Vera Connell, in collaboration with the British Commonwealth Scientific Offices (London). (British Commonwealth Scientific Conference.) Pp. vii+212. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1954.) 21s. net.

Nevertheless, it is worth looking a little more closely at the chapters on the communication of the results of scientific research in the volume arising out of the British Commonwealth Scientific Conference of 1946. The book is concerned primarily with the utilization of the results of research carried out under government auspices and, quite apart from the increasing extent to which both fundamental and applied research depend on government support, the shortcomings of the book may perhaps give a clue to some of the real causes of failure to secure effective development, or even to the real weaknesses in government-sponsored research. At least the complacency with which the adequacy of the existing arrangements is taken for granted should be challenged. When, for example, Sir Cyril Hinshelwood can write, as chairman of the Fuel Research Board, "On the basis of existing knowledge, and with no undue capital expenditure, the same amount of useful heat and power as are now obtained could be achieved with a saving over the country as a whole of several millions of tons of coal a year", it is time to examine not merely the receptivity of firms to scientific and technical information, but also the appropriateness of the way in which it is presented. We cannot assume that the multiplication of reports and scientific or technical papers, of liaison officers and the like will of itself achieve the object. The much more searching question of their appropriateness to their purpose must be asked.

On that point this report has little or nothing to say. As to whether reports or scientific and technical papers are actually read and understood by those to whom they are distributed, no evidence is offered. The validity of the existing methods of dissemination are taken for granted in the assumption that intensification or multiplication is all that is required. Yet the essential factor is the difference between securing the utilization or development of knowledge acquired as a result of some piece of investigation conducted or instituted by the firm itself, and the utilization of knowledge acquired from outside without its own effort. We cannot even assume that the latter process is parallel with the dissemination of scientific knowledge to scientists or technologists in general.

It is the psychological factor that is important and, however effective methods of overcoming it may prove, its existence is a reason for regarding with some reserve the tendency for the State to assume increasing financial responsibility for industrial research and especially technical development. Th selection of industrial research objectives can scarcel be as sound from outside as from within a firm, an from those two points of view alone the utilizatio of research results is more likely to be encourage by a government policy which encourages initiativ and enterprise by the individual firm than by actu government sponsoring of research and developmen Indeed, it might well be asked if a sound move t counter the prevailing sluggishness would not be fiscal policy which ceased to bolster up the inefficien firm and forced it out of existence.

Sir Henry Tizard has not concealed his ow uneasiness as to the rigidity of British industry an the dangers of relying on government initiative an support where development is concerned, if not al in regard to research. Moreover, where industry lacking in the spirit of adventure and in receptivit to new ideas, it is unlikely that such a defect will b corrected from the government side. In the Civ Service such defects are commonly accepted as pa of the price to be paid for its virtues and excellence It will be noted that, while the report records som of the activities, such as investigations into the rate technological innovation, which have been initiate by the Committee on Human Relations in Industr with funds from the Conditional Aid Programme, shows no appreciation of the urgency and importan of this work, if the obstacles to innovation ar development are to be overcome.

Such inquiries as are now being sponsored by th Committee on Human Relations in Industry ma well indicate ways and means for dealing mo effectively with human obstacles to the introducti of new production techniques and methods and new processes and products. Simultaneously, ho ever, the whole climate of industrial research an development in Great Britain requires examinati in relation to the application of existing knowledg There is room for more factual inquiry on questio which are commonly matters of opinion, as w recently pointed out in these columns (see *Natu* 174, 145; 1954); and the effectiveness of existin means of communicating knowledge should be n more immune from such inquiry than the relevan and appropriateness of the knowledge communicate or the ability and competence, as well as th receptivity, of those to whom it is supplied.

Admittedly, some such inquiries go outside t scope of the report contemplated by the Briti Commonwealth Scientific Official Conference in 194 but none the less, any critical appraisal of existin methods of promoting the utilization of resear results should have at least indicated the bearing such factors on the application of existing knowled and technological innovation. It should also ha examined the appropriateness of existing practic and considered whether or not some of the effo could not be better expended in other directions on new methods. It should not be assumed axiomatic, as this report appears to do, that all t existing effort given to the communication of resear results is necessarily effective and worth while. Ev if industry does need to employ more scientists a technologists at all levels, it no more follows that industry is being supplied with the information it most needs in the most appropriate way, or that all the existing information services should be maintained or expanded, than it follows that thereby the more fundamental psychological, economic or fiscal obstacles to innovation will be removed.

The report does not, it is true, overstress the part which methods of communication play in furthering the application of the results of research; but it does not seriously question the suitability of methods of distributing scientific and technical knowledge to the right places for utilization. "Information obtained through research represents in the aggregate very large expenditures of money and of the time, energy and intelligence of all-too-scarce trained men. Failure to make the fullest use of this effort is a flagrant waste which no country can afford. The responsibility for minimizing this waste must be shared by industry and research organizations. Management and labour must be receptive, and those responsible for research organizations must accept, as one of their primary duties, the task of ensuring that there is no waste of information through their default or neglect."

This, concludes the report, should be a cardinal point of policy, and it adds, "To give effect to it requires conviction of its necessity, continuous and close attention to its operation, imaginative but realistic choice of the methods to be used and persistence in their application". Nevertheless, no hint is given that this is exactly what is required of those actually engaged in the task of communication, and that the technique of communication and the trained man-power devoted to it are as appropriate a subject for scrutiny as the disposition of trained man-power in industry and in government service generally. The very fact that industry is already in fierce competition with the universities, with government departments and with the schools for the present supply of scientists makes it essential that such scientists should be wisely and effectively used, and not employed on duties which could be equally well performed by less highly trained persons.

Any such scrutiny of the use made of scientists in industry must include their use in information and like services, as well as in research. We should be as careful to satisfy ourselves that scientists are only employed in information work when their scientific qualifications are really essential, as will often obtain, as to ensure that industrial research is directed to objectives that are worth while; and neither duplicates what is being done elsewhere or is being pursued in fields unlikely to yield returns commensurate with the effort. What has to be realized is that every scientist engaged in such activities is one less available for the myriad other tasks involved in technological development, that each information officer or liaison officer employed on a non-essential task means one less available elsewhere, either for some essential part in winning the confidence of industry, in interpretation, or in training the fresh scientists and technologists that industry still needs.

All this is emphasized by even the limited comparative study of the organization of applied research in Europe and the United States and Canada made for the Organization for European Economic Co-operation. Most countries, it is clear, would benefit from an expansion of their research effort and from a close scrutiny of their policy with regard to research staff and their arrangements for co-operation, co-ordination and the exchange of information. Everywhere the critical factors are the shortage of qualified workers and their most effective use, and the inadequacy of allocations for research, and, especially in Europe, for the commercial application of the results.

Greater efforts in all countries, and also internationally, are recommended to ensure the more effective communication of research results and technique, and far more stress is laid in these reports than in that presented to the Commonwealth Scientific Conference on the importance of the personality of the liaison officer in the increasingly active industrial liaison service which is recommended. While once again it is emphasized that there is no lack of quality in European research, conditions in the United States are generally more favourable for applied research and industrial innovation. What is needed in Europe is a more frankly commercial initiative on the part of the applied scientist, and more direct support and recognition of the production and profit potentialities by industry and government.

Though there is much in these reports which repeats what has frequently been said in discussions on scientific and industrial research in Great Britain during the past ten years—the principles commended in the chapter on the research climate in the United States and Europe, for example, have been pressed in these columns for even longer—they make a number of suggestions, adoption of which might well help Britain to foster the enthusiasm for research which gives the United States so marked an advantage. We have still, for example, to formulate an adequate national research policy with the appropriate balance between fundamental and applied research, and scientists are reminded that when their work receives little attention and appropriations are not forthcoming, the fault may be partly their own failure to make full use of their opportunities for stating their opinions or selecting research projects of sufficient scientific or economic importance. Again, the need is emphasized for a constant review of the work and growth of government research organizations, and research councils are recommended to make a determined effort to collect and analyse data on investment in industrial research and development. A study is also recommended of the possibilities of minimizing the deterrent effects of taxation and encouraging both the commercial exploitation of research and the appropriation of funds for research.

What emerges particularly from this study is that for each country the organization and encouragement of applied research present a challenge to imaginative enterprise and to constructive thought. There is no general solution to the problems, however much the experience of other countries may assist any particular country in working out a pattern and solution appropriate to its own needs and conditions. Forms of co-operation even may differ, and while in the United States, for example, sponsored research institutes are already well established and the co-operative research association finds no favour, the situation varies considerably in Europe, where the field for sponsored research institutes depends on the extent and efficiency with which industry and government meet the requirements for research. No wholly satisfactory solution to the research needs of the small firm has yet been found; but on the other hand, the factors responsible for a satisfactory research climate are well understood and valid generally. The reports of these Technical Assistance Missions are well calculated to dispel any complacency engendered by that submitted to the Commonwealth Scientific Conference. Even in regard to documentation and the communication of results, they call for a critical review of existing methods and for active attempts to improve the means of communicating research results to industry; and the research worker himself is summoned to take part in this work. In particular, he is urged to examine the form in which information is supplied to him and, where appropriate, to indicate and press for better means. No scientist who reads the reports of these Missions is left in any doubt as to the importance of the contribution which he has to make, both personally and through his professional associations, to the constructive thinking and critical scrutiny of our whole organization for scientific and industrial research and for the means of disseminating the results of its activities. That thinking and scrutiny must precede alike the formulation of an adequate national research policy, and the devising of appropriate measures both to foster a real research climate and to overcome the obstacles, whether fiscal, psychological or technical, which hinder technological innovation in industry.

ANALYSES OF MARINE ORGANISMS

The Elementary Chemical Composition of Marine Organisms

By A. P. Vinogradov. (Memoir No. 2.) (Translated from the Russian by Julia Efron and Jane K. Setlow, with Bibliography by Virginia W. Odum.) Pp. xiv + 647. (New Haven, Conn.: Sears Foundation for Marine Research, Yale University, 1953.) 17 dollars.

THOUGH less than one-half per cent of the organisms that live in the sea have been submitted to any kind of elementary chemical analysis, much has been done. Analyses have become buried in a mountain range of journals, many highly inaccessible. There has been no means by which a research worker in a reasonable time could find what has been done in his own field. Full assessment of the part played by marine organisms in geochemistry has been impossible.

As part of the programme of Prof. V. I. Vernadsky's Biogeochemical Laboratory of the Academy of Sciences, Moscow, Prof. A. P. Vinogradov undertook the exceedingly onerous task of collecting and assessing this literature. He has published the results in the *Travaux* of that Laboratory in three parts in 1935, 1937 and 1944. These included much fresh and accurate analytical work from Russian laboratories by Vernadsky, Vinogradov and their school. Of these Russian publications, very few copies are available to the Western world. The reviewer knows of no accessible copy of the 1944 part in the British Isles.

The translation of this unique work into the English language has resulted from a happy Russo-American collaboration under the ægis of the American Museum of Natural History and the Sears Foundation of Marine Research. It is not a word-by-word translation by hacks but really a new work. The additions of the 1944 part were incorporated as appropriate in the earlier parts. The whole English translation was then seen by Vinogradov, who added new and unpublished material and made corrections. Still more recent material was added during editing and preparation for the press. There are also many helpful footnote commentaries by the translators. The bibliography of about 2,500 entries is essentially new and adds greatly to the value of the work for the advancement of geochemistry, marine biochemistry and systematics, oceanography, as well as of industrial biology and the science of petroleum.

One chapter is devoted to each phylum and may occupy 100 pages or less than one. For phyla much investigated such as algae, molluscs and fishes, the chapters are broken down into sections dealing either with single chemical elements or with single families. Owing to the difficulty of removing extraneous salt from the marine organism there has been much confusion in the meaning of such basic terms as 'wet weight'. Vinogradov has made order out of chaos, and future analysts of marine organisms would be wise to model their procedure to fit his classification.

The language of such a compilation is always likely to be repetitive, stilted and dull. In fact, this work is none of these, but has literary merit and holds attention by well-marshalled presentation and attractive writing. The technical production is superb and, in a book which will long retain scientific value, may be justified. However, in spite of heavy subsidy from the American Museum of Natural History and the Sears Foundation of Marine Research and the financial advantages of printing in Denmark, its price is so high as to place it beyond the means of most individuals outside the United States. Many would forgo the pleasure of consulting a collector's piece in a wealthy library for the advantage of themselves possessing a shoddier edition of an essential working tool. The cost of essential books which should be in a research worker's personal library is ever rising. Is there a case for again pressing on the Board of Inland Revenue, perhaps in the debates on the Finance Bill, the view that such costs are properly chargeable as personal expenses against taxation?

This book is as complete as any work of man is ever likely to be, but it cannot remain so. In a few years supplements will be needed, perhaps to the 327 tables with their numbers unchanged. It is to be hoped that the Biogeochemical Laboratory of the Russian Academy of Sciences, the American Museum of Natural History and the Sears Foundation may be able to achieve the preparation and publication in Russian and English of such supplements.

L. H. N. COOPER

THE RAW MATERIAL IN FOOD PRODUCTION

Soil

By G. V. Jacks. (Nelson's Agricultural Series.) Pp. ix+222+10 plates. (Edinburgh and London: Thomas Nelson and Sons, Ltd., 1954.) 12*s*. 6*d*. net.

THE problem of food supply will always be with us; it will not be solved by pretending it does not exist; it can be properly approached only through some knowledge of the soil, which is the basis of all agricultural pursuits. The brown or grey surface layer of the fields—the 'earth' to the uninitiated—is but the visible sign of an ageless development of soil, in the genesis of which parent material, climate, vegetation, topography and time are the factors inextricably related and on which man can finally exert an influence that may completely upset for good or ill the slow change of centuries.

What is soil in its origin, physical and chemical properties, fertility, utilization? These are the questions that are dealt with in this book, the fifteenth in the Nelson Series for farmers and students of agriculture, and one that could also be profitably read by any others seriously interested in the question of food production. As becomes a writer with an enviable reputation and a wide knowledge of his subject, the text carries the stamp of authority; it is a straightforward statement in plain English of what we know and what we do not know, with the emphasis on general principles and the interplay of factors. Mr. Jacks has, in fact, most ably achieved his aim of presenting an interpretation of the scientific facts in language comprehensible to the non-specialist reader.
